A word in reference to the situation of the peach orchard. To guard against late Spring frosts, avoid low, rich ground, and choose rather high and rolling land. Here the trees may grow less luxuriantly, and the fruit ripen a little later, but frost and various diseases will make less trouble. It is a mistake, however, to suppose that the peach is partial to a poor and thin soil. It is often put into this, as in Delaware and New Jersey, because this land will yield no other crop so remunerative. It is chiefly because of the poverty of the land that the peach orchards there are so short-lived, often flourishing no longer than three or four years. Give the peach a good, substantial loamy soil, well drained and moderately enriched, and it will very often remain productive fifteen or twenty years.

In setting out a young orchard, choose fresh land. Plant the trees 16 feet apart unless you know that they are likely to live more than 12 years. Give the land a light annual dressing of manure, and keep it well stirred. After the trees have begun to bear plentifully, no other crop should be taken from the land.

They may be pruned during the growing season to advantage, by pinching in the shoots in such a way as to give a compact and uniform top, and keep the fruit more within reach. The tendency of the sap, the most rapid growth, and much of the fruit, are always towards the ends of the limbs, and thus, each year, our pruned trees stretch away further and further from the ground. Pinching in gives larger and better developed leaves, better buds for next year, and greater perfection to the fruit, which is borne both on year old, and still older wood. The blooming is so profuse that little fruit is lost by pruning. When thus shortened in in Spring or Autumn, better the former, cut back, leaving only four or five good buds on wood of the past season's growth, and remove at the same time all side shoots that fill up the tree too much.... The experience of Mr. S. S. Gregory, Cuyahoga Co., O., is interesting on some of the points, and we give it as he writes to the *American Agriculturist*:

"Fourteen years since I purchased fifty peach-trees, at eight cents a piece. One of these trees was of "natural fruit," and the remainder were of four sorts: the Melocoton, Morrisania, and the Red and Yellow Rare-ripes. The soil upon which they were set varied in character, part being a gravelly dry loam, tolerably well calculated for peaches, and part just the reverse, low and wet. Since setting out, part of the trees have yielded fruit four times, while a part died without producing enough to pay for the cost and trouble of planting them. As near as I can estimate, besides a bountiful supply of peaches for my own use, the receipts for the fruit sold from the bearing trees have been amply sufficient to pay for all the trees originally purchased, *and for the land upon which they stood.* The chief, and perhaps the sole reason why the bearing trees failed to bear, ten of the fourteen

years, has been hard freezing, which combined with a heavy wet undersoil, killed part of the trees, and materially injured the remainder. Of the fifty trees originally set out, there are now about a dozen remaining alive, and these, with the exception of the one bearing natural fruit, which was bought through mistake, give unmistakable signs of old age. And yet, in 1860, these decrepit trees yielded fruit sufficient to pay for all their cost and the land upon which they stand. In my experience with these trees and about one hundred and fifty others since set out, I find invariably, where the trees were set on land having little gravel or sand, and where the subsoil was heavy and wet, they either died or became so withered as to be of little use—except as a lesson to those setting out peach trees. I find that mulching the trees with straw, leaves, etc., is profitable. It helps to keep a sod from forming round the roots, and greatly promotes the growth of both trees and fruit by preserving a proper degree of moisture. I find that trees of the same sort produce very different sized peaches according to the soil in which the trees are planted; but the size materially depends also upon the number of peaches on any tree. Often trees having only one or two hundred peaches on each, will have fruit of double the size of those which are loaded down to their utmost capacity of bearing. And on the highest limbs where comparatively few peaches grow, the fruit is of a size much larger than on the lower limbs which had many peaches on them. The fruit on a few of my trees was of an inferior quality, on account of my setting them in localities where the ground was too rich."

Experience with Dwarf Pears.

Nothing is more various than the experience of cultivators with this fruit, and nothing more unsettled than the dwarf pear question. Meet one fruit grower, a little enthusiastic, and pump him on this subject, and he tells you that nothing is easier than growing fine dwarfs. Look into his garden, and you see them—splendid pyramids, the bark as clean as the skin of his favorite colt, the limbs coming out nearly at right angles, and loaded with handsome fruit. Look at the further end of his garden, and quite likely you find a tub of soap suds, sink water, or fountain of liquid manure, which reveals the secret of his success. Meet another gentleman, and he tells you dwarf pears are a humbug—a wicked device of nurserymen to impose upon the public. Look into his fruit yard, and you see them dying, dead, bored at the collar by worms, sap blighted, covered with scale bugs—a very good basis for the owner's opinion.

What is the truth upon this subject? Both these men are right. Dwarf pears are a success with the first man, because he takes care of them, and a nuisance to the latter, because he pays no attention to them. I have been cultivating pears since 1850, and have now about 150 trees, standards and dwarfs. The first trees planted were suckers, contrary to the advice of the books, and to the practice of the best pomologists. They were respectively budded with the Flemish Beauty, Louise Bonne de Jersey, White Doyenné, and Winter Nelis, and have never thrown up a sucker. The last two bore for the first time last year, though they have had good cultivation, plenty of manure, and have been shortened in every year. The others began to bear three or four years earlier. They are all well set with fruit buds, this year, and will bear, probably, a full crop. It is a work of time to make a standard pear tree. The next lot was from a traveling agent of an unknown nursery. They did poorly, but with careful nursing got to growing in about three years, and two only, one a dwarf and the other a standard, have made good trees. The standard is a Muskingum, which bore for the first time last year, ten years from the planting. It comes about ten days earlier than the Bartlett—is nearly as large, and to my taste, is better. It is now full of fruit buds, and is making wood fast enough. The dwarf is of unknown variety, bears well, and is growing rapidly. Eight years ago I budded a Flemish Beauty and the Glout Morceau, upon the common Orange Quince. They are among my most thrifty, handsome, and fruitful trees.

A White Doyenné from the nursery, on quince, began to bear the second year, and bore itself to death in three years. The fruit was fair, and without cracks. It was my ignorance that killed it. Another, budded upon a common quince, has made but a poor growth, and never will amount to any thing.

About five years ago I bought a lot of dwarf Louise Bonnes from an honorable nurseryman. They had been in bearing a year or two, and I let them continue to bear, until at this time they are all dead but one. This was my fault.

I bought two Glout Morceaus and three Vicars, dwarfs, about ten years old, the following season. Owing to a second removal two of them died. The other three grew vigorously, and the Vicar has borne fine crops every other year. All are making wood fast enough, and are doing as well as I could desire. Two Epine Dumas bore well for three years, and were destroyed by grubs. This was also my fault. They should have been planted deeper, and have been examined more frequently. This is one of the new pears, an abundant bearer, of excellent quality, ripens in November, and is worthy of a further acquaintance. The Andrews and Bloodgood are hard cases. I could never make them flourish, and after many trials, have not a tree that I should like to show to my neighbors. Have two Dix on quince—one dead and the other alive, but not flourishing. The standards grow, and possibly my grand-children will eat fruit from them, if they occupy the homestead. The dwarf Urbaniste trees have grown finely, but have borne no fruit, six years after planting. The Beurré d'Amalis does well, both as dwarf, and standard, but the fruit is not first rate.

The Buffum makes a tree and fruit that I am altogether pleased with. It grows uniformly in the Lombardy poplar shape, occupies little room, looks "genteel," and is just the tree to plant beside garden walks and avenues. The St. Ghislain, and the Seckel also look well in the same localities. The Buffum looks temptingly upon the tree, and is good enough upon the table. It is one of the best sorts for the seashore, near which it originated. The same may be said of the Flemish Beauty. The Bartlett does so well, and bears so easily as a standard, that it seems a mistake to dwarf it in any case. The only way in which I have been able to get any wood upon young trees, is by persistently cutting off the blossom buds. If this is done for the first five or six years after planting, you can make a vigorous tree, of good form, that will give abundance of good fruit in due season.

I find as the result of my experience, that I am running more and more to standards, though I have still faith in the utility of dwarfs for the garden. Do not touch them unless you have manure in plenty, and mean to take care of them. Nothing but cultivation will make dwarfs a success. CONNECTICUT.

Shad-bush or June-berry as a Pear Stock.

Mr. Charles B. Ott, nurseryman in Bucks Co., Pa., says he has used the June-berry, (*Amelanchier Canadensis*,) for a stock on which to graft the pear, and after 18 years' experience is well satisfied with it for some varieties, while others fail after 10 or 12 years. The Seckel does remarkably well on the amelanchier stock, bearing very fine fruit. Mr. Ott worked his trees four feet from the ground, but would advise budding them close down, as low as on the quince stock. He thinks the native June-berry, (known in New-England, New-York, and Ohio, as shad-bush or shad-blow), has been too much overlooked, both as a stock on which to work the pear, and as a fruit and ornamental tree of itself. The tree, or rather shrub, grows from 15 to 20 feet high, is of graceful form, covered in Spring with handsome flowers of snowy whiteness, hanging in racimes; while the round, purple fruit, nearly as large as the mazzard cherry, is sweet, and not unpleasant to the taste, and very likely susceptible of improvement. As the name indicates, the berries are ripe in June, before other fruit is in eating condition.

For the American Agriculturist.

Transplanting Evergreens from the Forest.

"This," you say, in the *Agriculturist* for April, (p. 102,) "is a somewhat uncertain operation."—So it is as usually practised! The method you propose, I think, would be almost certain to succeed, but it involves the delay of a year, and can be practised only where the trees to be removed stand singly in an open pasture, certainly not where they are found in "the forest."

The Hemlock (*Abies canadensis*), and the common White Pine (*Pinus strobus*), are probably as difficult to manage as any that can be named, and may be taken as representatives of their class; but a little study of their habits will aid us greatly in determining the proper time and also the proper mode of transplanting them!

These trees put forth their shoots only once in the year, and then only at the ends of the twigs where preparation was made the preceding Autumn by the formation of buds. These buds begin to start in the Spring as soon as the weather becomes warm, but in this latitude they make little progress until some time in the month of May, and the growth continues until the middle or last of July. The remainder of the year is required to mature the wood thus formed. This rule seems to be absolute for these two specimens; and you look in vain for the appearance of a shoot or twig not in conformity with it! And the same rule holds in regard to the roots, which put forth their shoots at the same time, and probably in the same manner!

Does not this plainly indicate that the proper season for transplanting these trees is at the time when the shoots are starting, or during the time of their vigorous growth? Does it not as plainly indicate the impropriety of attempting it at any other season? It shows also the absolute necessity of preserving as large a part of the roots unbroken as possible, as it is only from the very ends of the little rootlets that the new ones will make their appearance.

My own experience and observation in this region incline me to believe that the best time for transplanting these evergreens is as late as the first of June or even later. And done at this season, and in a proper manner, they are nearly as certain to live as any other trees! J. J.

Middletown, Conn., April 18, 1862.

Engraved for the American Agriculturist.

Kinds of Fruit—A Botanical Description.

BY T. D. BENNETT.

The organs of a flower are of two kinds (1st,) the *protecting* organs or leaves of the flower, consisting of two circles of leaves, the outer called the *calyx*, the inner the *corolla*. (2nd,) The *essential* organs, which are also of two kinds, *stamens* and *pistils* placed one above or within the other. The stamen consists of two parts, the filaments or stem, and the anther, a case which contains the yellow fertilizing dust, called *pollen*. The pistil is in three parts, (beginning from below,) the *ovary*, a hollow case containing rudimentary seeds called the *ovules*, second the *style*, the tapering part above, third the *stigma*, the tip of the style consisting of loose tissue, upon which the pollen falls, when the ripe anthers open. Referring to the flower (1) in the engraving—(a) is the calyx, (b) corolla, (c) stamens, (d) the pistil, with the ovary showing the ovules within. The pollen upon being discharged from the anthers falls upon the stigma and communicates an influence down the style into the ovary: the ovules thus fertilized become seeds, which ripening, with the ovary, constitute the fruit. Proper fruit then is this ripened ovary called seed-vessel or *pericarp*, containing the seeds. Sometimes the calyx (a) adheres to the ovary and thus becomes a part of the fruit, and even forms the principal bulk of it, as in the apple.

Fruits are divided into simple and multiple. Fruits of the former class consist each of a single ovary, one or many seeded, and are classified as Fleshy fruits, Stone fruits, and Dry fruits, etc.

In FLESHY FRUIT the walls of the ovary thicken and become soft and juicy. The principal kinds of fleshy fruits are the following:

The Berry which is fleshy or pulpy throughout. The grape, gooseberry (3), currant, tomato, etc., are good examples. The orange, the lemon, the shaddock, etc., are berries with leathery rinds.

The Pepo, or *Gourd fruit* (15), is also a sort of berry, externally firm, and internally pulpy. Cucumbers, melons, and squashes are illustrations.

In the *Pome* (2), such as the apple, pear, and quince, the calyx only is thickened, the star-like core in the center is the ripened ovary.

Of STONE FRUITS the most familiar kind is the *Drupe* (11), such as the cherry, plum and peach. In this, the outer part of the ovary becomes fleshy, like a berry, while the inner hardens like a nut. The blackberry and raspberry are composed of a great number of miniature stone fruits, like cherries, upon an elongated *receptacle*, as the end of the flower stalk is called.

In DRY FRUIT, the seed-vessel remains herbaceous in texture, or becomes thin; or else it hardens throughout. Some forms are *indehiscent*, that is, remain closed; others are *dehiscent*, that is, split open at maturity in some regular way. The principal indehiscent kinds are the following:

The *Achenium*, or Akene. This may be mistaken for a naked seed; but it is a ripened ovary, the remains of its stigma being plainly seen. Of this sort is the fruit of the Buttercup (13). The crown on the top of some species of akene fruit is called *Pappus*; in some it represents a cup, in others, scales, as in the sunflower (9); in the thistle, aster, dandelion (6), and hundreds of others it is cut up into a tuft of fine hairs.

The *Utricle* is the same as an akene, with a thin, bladdery pericarp; as seen in the pigweed (12).

A *Caryopsis* or Grain differs from the last by the seed filling out and adhering to the pericarp, so that fruit and seed are in one body; as seen in wheat, Indian corn and other kinds of grain.—A *Nut* is a dry indehiscent fruit, commonly one-celled and one-seeded, with a hard bony wall or shell, such as cocoa-nut, hazlenut and acorn (7).—A *Samara*, or *Key fruit*, is either a nut or an akene, furnished with a wing, like maple keys and seeds of the ash, (17), and elm.—The *Capsule*, or *Pod*, is the general name for dry seed-vessels which split open at maturity. There are several sorts distinguished by particular names. Two have simple pistils, namely:

The *Follicle*, a simple fruit opening as in larkspur, columbine, marsh marigold (5), and the *Legume*, a true pod like the pea (4), this is similar to the follicle only it opens at both sides.

The true *Capsule* is the pod of a compound pistil. The difference between a simple and compound pistil can be seen by comparing the pea (4), and marsh marigold (5), with the triangular fruit of the Iris, or Flower de Luce, (18).

The *Silique* (16), the pod of the mustard family, differs from the legume by having a so-called false partition, to which the seeds are attached.

The *Pyxis* is a pod which opens by a horizontal line, one part forming a lid, as in purslane (10).

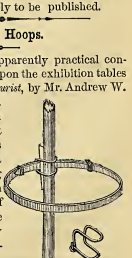
Multiple or *Collective Fruits* are masses of fruit, resulting from several blossoms, aggregated into one body, as the pineapple, mulberry, and fig.

The Strobile or *Cone* is a scaly multiple fruit. The hop is one species where the large scales are bracts; but the name more especially belongs to the pine or fir cone. The scales are *open pistils* overlying each other and pressed together in a spike; 14 is one of these scales of a pine cone.

In this description all the principal kinds of fruit are embraced. Those who may wish a more elaborate description we will refer to Gray's Botanical Text Book. The sketch accompanying is furnished to the *Agriculturist* from a Botanical Plate, probably to be published.

Dahlia Hoops.

A very simple and apparently practical contrivance has been left upon the exhibition tables of the *American Agriculturist*, by Mr. Andrew W. Nicholson, of Brooklyn.



A stout wire is bent in the form shown, so that placing the curved parts of the wire against a plant stake, and passing a barrel hoop through the other looped ends of the wire behind the stake, it may be securely fastened at any elevation on the stake by a wedge placed between the hoop and the stake as represented. The ends of the hoops are secured by two rings of tin or zinc, which allow them to slide freely through, and the hoop thus be enlarged or contracted at pleasure.

Annual Flowers.

We do not wonder at the increasing interest felt in annual flowers. They are the flowers for the million. The seeds for raising them cost but a trifle, many can be got by exchange, or will come as gifts of friendship. And when one gets a good assortment, he can, ordinarily, perpetuate it from year to year without much trouble. Certainly, the work of seed-sowing is less than that of housing bedding-plants through the winter, propagating them by cuttings, potting and repotting, watering, fumigating, and then repotting in the open border. Look at these varieties: Drummond's Phlox, the Double Zinnia, German Stocks, the splendid French Asters, and the new Japan Pinks! The most aristocratic garden would be tame without them. But after all, these and all annual flowers will generally give satisfaction just in proportion to the care that is given them. If sown in hard, barren soil, of course they won't succeed. If huddled together, the matted roots will soon exhaust the ground in which they stand, the leaves and flowers will be imperfect and of short duration. With a few exceptions, annuals should be grown as separate plants, with plenty of room on every side for full development. This needs only to be once tried to convince all gainsayers.

Hints for Lady Florists.

One of the greatest mistakes made in flower-gardens every year, is attempting too much, and crowding the grounds. "My lady" visits several fine gardens, during the Summer, and sees brilliant novelties which she thinks she *must* have next year. Or she gets several nursery catalogues, and reading the high sounding descriptions of plants, she orders more than her garden can well hold, or than she can take care of. The consequence is they fail to do well, and she and her visitors are not satisfied with the effect.

A much better way is, to sit down at the beginning of the Summer, and settle in one's mind how much *room* there will be for new things, and what are, on the whole, the *best*. Get only these, and take the best possible care of them. Give them the right soil, and keep it clean and well stirred. Keep the tall plants neatly tied to stakes. The edgings to the beds should be always well trimmed, the walks clean and hard, and the whole ground neat and tidy. Such a garden will always give satisfaction.

Easy Method of Killing Insects.

For all moths, and beetles that fly at night, use fire to trap them. A fire of shavings, or any thing that will make a blaze, kindled in the evening, will destroy thousands. The more flame the better, if it do not scorch the leaves. A cheaper method still, is to take the half of an old sugar hogshead, or any open vessel, with a broad surface, partially filled with water, and set a lighted glass lantern on a block or stone, in the center of the water at night. The moths are attracted by the lantern and its reflections, and fall into the water. The advantage of the sugar hogshead is, that it serves for a trap by day, as well as by night. For moths that fly by day, we take wide-mouthed glass bottles, half fill them with sweetened water and vinegar, and hang them in the trees, changing the liquid weekly. Thousands of insects are drowned.

"The Hermitage."

On former occasions, we have spoken of the desirableness of creating rustic scenes in pleasure grounds. We now recur to the subject for a special purpose. These wild scenes should not be very near the dwelling, but rather in a retired corner at a distance, where some little touch of natural roughness may be wrought into the artificial creation. Perhaps there is a brook at hand, which can be made to tumble over rocks, into a pool for fish. Along this brook-side, ferns, lilies, and other wild plants may be set. Perhaps there is some spot that can be converted into a *rockery*. Whatever and wherever it may be, let as much as possible be made out of the *natural capabilities* of the place.

To illustrate our ideas, we will describe a rustic scene which has been created in the grounds of a friend, hard by—partly represented in the annexed wood-cut, which we have sketched for the *Agriculturist*. The ground at the left in front of this arbor, is an open, highly finished lawn. The walk which skirts one side of it is kept in fine condition, and a Warwick Vase gives the spot an air of classic elegance. Nothing suggests the idea of rustic wildness. But as the visitor descends a slope in the walk, on the left, he comes among masses of shrubbery, and on turning to the left, suddenly finds himself in the shady arbor shown in our picture. Let us tell how this arbor was made. Six years ago, the proprietor planted fourteen small, low-branched elms around the open space here shown. The second year after, he built a rough arbor of hemlock scantling and slats, just inside of this semi-circle, about ten feet high, and twelve feet in diameter. The trees were then bent over the arched and open roof, and tied down with strong cords. The branches were spread out evenly, like grape-vines on a trellis. In a few years, by pruning and tying in the branches, he covered the arbor with a close network of limbs and twigs, which the summer sun scarcely penetrates. After the branches overhead shall have become more firmly intertwined, he will remove the frame-work, leaving the trees alone to make the arbor as represented.

But the above is not the whole of this Hermitage. For a space of eight or ten feet wide around it, our friend has set all sorts of low bushy trees from the forest, and among them has planted wild vines from the woods. And outside of this, runs a thick screen of arbor-vitæ. The walk, on leaving the arbor, passes into a little woody scene with trees and vines on either side, and arching overhead. Here, and immediately around the arbor, it is attempted to make a miniature wilderness. Throughout the whole of it, the natural soil of the place has been removed, and leaf-mold from the woods brought in. This, with the shade above, furnishes a congenial home for the wild plants, of which there is collected here a large number from the neighboring forests. One or two large bowlders being found on the spot, our friend has hauled in a number more of like character, which now look very much at home. Wild plants and vines clamber lovingly around them. The walk on the right, after winding through a darkly shaded spot, emerges again upon another pleasant open lawn in front of the dwelling.

In the open space of the arbor, seen in the cut, the natural soil has been taken out eighteen inches deep, and the space filled with cobble-stones and gravel, so that the ground is perfectly dry. A few rustic seats are placed in the arbor, which are very agreeable resting-places on a mid-summer noon. The place described, our friend's family style their "Hermitage." They have a separate flower-garden, and ornamental grounds, but nothing which, on the whole, gives them or their guests greater satisfaction with so little labor and cost.

Preserving Fruit—Best and Cheapest Way.

For several years past we have been trying to abolish the old mode of preserving fruits, viz: the addition of pound for pound of sugar, and stewing them down to an indigestible mass in order to make them "keep." Our efforts in this direction have been in a measure successful; the high price of sugar this year will do much towards the adoption of the newer and better mode. All kinds of fruits can be preserved for a year, or more, with the use of little or no sugar, and at the same time retain nearly all of their natural flavor. The process is not more difficult, and is less costly than the stewing process, while the fruit is far more delicious and healthful. The whole operation depends upon simply heating the fruit through, and then keeping it entirely free from the access of air.

Fruit Jars.—Periodically, as the fruit season approaches, there are numerous fruit jar inventions, patented and otherwise, brought before the public with wonderful assurance and an indefinite number of extravagant recommendations. Some seal with

wax, others with India rubber and cast iron; in some the tops are screwed on; in others, wedged; and in others wired. Some tin, some glass, and some stone, but *all* are "perfect," if the claims of the inventors and manufacturers are fully credited. We have tried most of these fruit jars, and while many of them are good, our experience has led us to adopt the cheapest kinds of glass bottles and jars. Tin cans are not safe. While in a majority of cases they may answer well for a season or two, there is always danger of their corrosion, or rusting, and the consequent production of poisonous salts of tin. Besides, it is desirable to have the fruit in transparent vessels so that it can always be examined. Good well-glazed stone-ware bottles and jars are not objectionable on account of corrosion, but they are opaque, so that the contents can not be seen, and are but little cheaper than cheap glass.

During the past year we have kept several bushels of fruit of different kinds, always in good condition, and the portion now unused is almost as fresh and delicious as when first picked. For keeping, we have used all sorts of *glass* bottles and jars, holding from a pint to two quarts each—including several of the patent jars with caps of various patterns. Among these were a dozen glass jars with India rubber rings expanded by a compressing screw, of which five gave way and the fruit was lost. Of the common glass bottle and jars we have not lost one.—There is hardly a glass bottle of whatever form that can not be turned to account for preserving fruits—even junk bottles, soda-water bottles, jars, etc., etc. The *best* form is a wide-mouthed quart bottle or jar, the neck drawn in to give a shoulder for the cork to rest upon. For the larger fruits wide necks are needed; for the smaller, berry fruits, narrow necks answer perfectly.

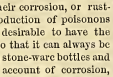


Fig. 1.

Fig. 2.

Fig. 3.

PREPARING THE FRUIT.—Our method is, to put the fruit in a preserving kettle of some kind—a glazed iron kettle, or even a tinned one, or a tin pail will do—and sweeten it with just sugar enough to fit it for the table. The sweetening is added in the form of a syrup made by boiling from one to three pounds of sugar (usually 2 lbs.) with one quart of water. The more juicy fruits, such as strawberries, require less syrup, while pears and quinces require more. The fruit is heated with the syrup just long enough to scald it *through*. Some prefer to use less sweetening and add more when the fruit is to be used. Others use no sugar; they think the fruit keeps just as well, and preserves its aroma better without any sugar. We prefer to use all the sugar that is to be needed, believing that the fruit will probably keep more certainly, and it is then always ready to pour out at once upon the table. The fruit to be preserved should be in good condition—ripe, but not over-ripe, nor containing any decayed portions. Tomatoes are peeled, and then cooked down one-half, as this makes a better sauce, and requires less bottle room.

TO BOTTLE THE FRUIT.—The bottles or jars are thoroughly cleansed, and each one fitted with a stopper. For these, soft corks are best; but they may be made of soft dry wood. For each bottle or jar we provide a little tin "patty-pan," (fig. 1,) costing ½ to 1 cent each by the quantity. Tea-saucers will answer. For *cement* we heat together in an old tin basin or iron kettle, one pound of rosin, and 1¾ to 2 ounces of tallow. This may be mixed in quantity, and melted from time to time as wanted. We formerly used a little over 1 ounce of tallow to one pound of rosin, but further experience is in favor of a softer cement, when the fruit is to stand in a cool cellar.—While the fruit is being heated as above described, the bottles are well warmed by setting them near the fire and frequently turning them; or better, by setting them in cold water in a wash-boiler and heating to the boiling point. The fruit being barely scalded *through*, it is dipped hot into the heated bottles, through a funnel if the bottle necks are small. This is done carefully, so as not to mash the fruit. The bottles are filled up to where the bottom of the stoppers will come; they are then jarred a little to make the air bubbles rise, and more fruit or syrup added if needed. The tops and necks are then wiped clean, inside and out and the stoppers put in, and sunk to a level with the top. The cement being warmed in the mean time, a little is dipped on over the stoppers to close them tightly. The bottles are then turned necks down into the little patty-pans, or saucers, (fig. 2,) and a quantity of cement dropped in to completely enclose the stoppers and necks. When cold the bottles may be set either side up, (fig. 2 or fig. 3). The cooling will shrink the contents so as to create a strong inward pressure, but the patty-pans prevent the stoppers from being pressed in, and the cement shuts out air.

The whole process is simple and quickly performed. After the fruit is prepared, two persons will heat it, and put up 50 to 100 bottles in half a day. We prefer quart bottles as these furnish enough for once opening. If cork stoppers are used, they are rendered soft and pliable, and may be crowded into a small orifice, by first soaking them in hot water.

SUBSTITUTE FOR PATTY-PANS.—The patty-pans are simply circular pieces of tin, stamped in the form of a cup or plate, 3 to 3½ inches across. We buy them at wholesale for 87 cts., or $1.25 per gross. But any kind of cup to hold the wax, will answer. We have seen the common blacking boxes used, bottom for one jar or bottle, and the top or cover for another. Blocks of wood, or bits of board, cut out into cup-form with a gouge, or bored only partway through with a large augur, answer every purpose. They should be partly filled with cement, before turning the bottle into them. No one need look far for the materials. The old bottles about the house, thoroughly cleaned, the tin boxes, or old saucers, or wooden blocks, and some rosin are all the apparatus needed.

Fig. 4.

ANOTHER METHOD.

An associate editor of the *Agriculturist*, who has successfully practiced the general method above described, recommends a substitute for the stoppers and patty pans, which he has used for some years, and successfully. Pieces of Canton flannel are dipped in heated grafting wax made by melting together 2 parts bees wax, 2 parts rosin, and 1 part tallow. After dipping they are laid, cotton side up, upon sheets of rather light, white printing paper, on a smooth table and additional wax laid on, and the air bubbles rubbed out if necessary. The cloth must be perfectly saturated with the wax, but a large quantity is undesirable. Glass jars are used with a so that the waxed cloth may be conveniently bound on. They are hot, when filled full, with the boiling hot preserves; the prepared cloth is cut into convenient squares of generous dimensions; and the jars or bottles are jarred a little, repeatedly, to force the escape of any air bubbles. The cloth caps being slightly warm are laid, wax down, upon the mouths, and the hand passed over the rims with a firm pressure; then with a stout cord or packthread wound round and round, the edges of the caps are bound down upon the neck of the bottle or jar. As soon as the bottles cool, a depression of the cap will indicate that they are airtight, while the least hole will prevent this concavity, and thus indicate at once the necessity of repeating the sealing process. Should the fruit ferment an inflation of the cap will be noticed, provided the jar is tight.

Washing Machines.

The hard work of "Washing-day" has led to much effort on the part of inventors, to supply some kind of labor-saving machines to lessen the toil of the house-wife. The amount of ingenuity exercised in this particular direction has been so great, that there are now in the Patent Office at Washington, more than *eight hundred* models of patented washing machines, we believe. Yet, notwithstanding their great number, and the amount of advertising and other efforts to bring these machines before the public, in how very few families is there now a washing machine in actual use. There are plenty of them lying unused in the garrets or outhouses—the strongest evidence that, however good in theory, few of these machines stand the practical test. We have tried a score of them, yet all but two have been thrown aside after a patient effort to make them work profitably. The "Metropolitan," with its sixteen spring pestles, working upon a spring pole, is almost perfect, at least it does the work well without injuring the garments. The "help" complain that it is "hard to work"—but they are "constitutionally" opposed to all Yankee machinery, and we do not attach much importance to their complaints. The other, the "Nonpareil Washing Machine," we have now had in use for several months and it has stood the test of actual trial quite as well as any machine we had previously sent home. It is somewhat like the old-fashioned "fulling mill," and certainly "beats out the dirt" without damage to the garments. It is operated by a crank and has a heavy balance wheel which equalizes the force so as to make it work quite easily. On the whole, we are much pleased with it.

For the American Agriculturist.

Making Double-Curded Cheeses.

Many farmer's wives despair of making this great luxury, to say the least, because they have not cows enough. Some years ago, when we first commenced farming, I made very good cheese from six cows, by making them "double-curded." During the first half of June, milk will generally keep sweet, (in a cool place), 36 hours, so that two days' milk can be run up into one curd. To keep the curd over, it must be well drained off in a cheese basket; a coarse linen cloth is the best to wrap around the curd, and a board and weight should be laid on top to press out the whey, after which it may be hung up in the cellar, or in a cool pantry, until wanted. While our second curd is getting ready, we have our first cut up in small pieces of the size of kernels of corn and soaking in lukewarm water, to take out the sourness; a second water too is generally necessary. We find by experience that each of the two curds had better be scalded by itself, as they *run* together when scalded in one vessel. After salting and partial cooling, they can be mixed while putting into the hoop without any such result, and quite just as well, and taste as well, as a single curded cheese. MRS. M. J. S.

Fairhaven, Ill.

A Novel "Pumpkin Pie."

A NEW-JERSEY BACHELOR KEEPING HOUSE.

DEAR EDITORS:—I suppose you will not object to my talking with the good housewives who read the *American Agriculturist*. As I am a bachelor and must necessarily meddle with the household affairs, I deem it serviceable to study the mysteries of housekeeping. Some friends call me "Pot Betsy," and my fair city cousins think me over nice and fussy. Of course I don't care for what they say (?), and am very glad *this* house is comfortable and attractive enough to lure my most fastidious city friends to come and visit me. Pray, madams, don't think that

I do all the delicate work, for I employ my farmer's tidy wife, here. Now you know what I am, and will, I trust, allow me to tell you about a mysterious pie.

Yesterday I sat down *alone* with my venerable father at dinner, and noticed a nice *pumpkin* pie on the table. I was really surprised, because I was sure there was not a pumpkin in the house. We tasted it, and declared it to be made of pumpkins, but wondered where the housekeeper got them, and after dinner I asked her. She laughed and said it was made of turnips.—Turnips? Yes. I proposed to render her name famous by asking her recipe to be published in the *Agriculturist*, she smiled, pouted, and went out. Here is the recipe: "Take two good sized yellow turnips; clean and peel them; boil about two hours and mash them. Then add 1 pound of brown sugar, 4 eggs, 2 quarts of milk, ½ cup of molasses, 1 spoonful of ginger, 1 nutmeg, ½ cup of wheat flour. This is then used the same as in making the real pumpkin, or custard pies. MRS. L. E. VAIL." A word more from the Bachelor.

A BEEF'S HEART.

The other day I ordered a beef's heart to be cooked according to a part of the recipe of "H." of Genesee Co., Mich., (in the March *Agriculturist*) and part of that of J. Langdon, Vinton Co., O., in the same paper: as follows: "Gash it, and fill it with beef suet, bread, eggs, parsley, nutmeg, pepper and salt, and boil it." Can I consider this compounded recipe my own? It is very excellent, and I, an old customer of Delmonico, would be quite willing to pay 40 cents per plate for it. J. H. R.
Passaic Co., New-Jersey.

Rhubarb Wine.

A fair article of wine for family use may be made from the juice of the rhubarb in the following manner: Grind or mash, and press the stalks, in any convenient manner. A portable or hand cider mill and press answer well for this purpose. Add as much water as there is juice, and 3 to 4 lbs. light colored sugar to each gallon of the mixture. Put in casks and set in the cellar, with the bung out, leaving it until fermentation ceases, keeping the casks *full* in the mean time. When done working, bung up tight or bottle for use. Small quantities may be put at first into glass bottles or stone jugs.

Double Heeled Socks.

An anonymous correspondent, referring to our engravings and directions, in the Dec. *Agriculturist*, for knitting socks for Soldiers and others, writes: "Would it not be better to make double heels? This is easily done by knitting a stitch and slipping a stitch on the wrong side, and knitting every stitch on the right side."

A Cat's Tenacity of Life.

Cats sometimes seem to have a wonderful hold on life, so much so that the "nine lives of a cat" has passed into a proverb. Mrs. O. G. N. of Black Earth, Wis., gives the following in a note to the *Agriculturist*:

"Our old cat was the pet of the family. When we resided in Rochester, on the banks of the Genesee, one Winter pussy began to grow cross, and from some unaccountable reason, her *good natured fits* became "small by degrees, and beautifully less," until we were in danger of getting roundly scratched if we meddled with her ladyship in the least. My mother finally induced me to part with my pet, and the boys carried her in a bag to the bridge which spanned the Genesee, just above the falls. They "*let the cat out of the bag*," and saw her take the perilous descent over the small fall, just above the main fall, over which she must also have plunged, in imitation of unfortunate Sam Patch. After *ten* days pussy came home, and begged to come in. I was fairly afraid of her at first—thought it might be her *spirit*, but I assure you she was tame enough ever after. She fairly earned her title to the tenth life, which the icy waves had spared.

June.

BY JAMES RUSSELL LOWELL.

"And what is so rare as a day in June?
Then, if ever, come perfect days;
Then Heaven tries the earth if it be in tune,
And over it softly her warm ear lays;
Whether we look, or whether we listen,
We hear life murmur, or see it glisten;
Every clod feels a stir of might,
An instinct within it that reaches and towers,
And, grasping blindly above it for light,
Climbs to a soul in grass and flowers;—
The flush of life may well be seen
Thrilling back over hills and valleys;
The cowslip startles in meadows green,
The buttercup catches the sun in the chalice,
And there's never a leaf or a blade too mean
To be some happy creature's palace;
The little bird sits at his door in the sun,
Atilt like a blossom among the leaves,
And lets his illumined being o'errun
With the deluge of Summer it receives;
His mate feels the eggs beneath her wings,
And the heart in her dumb breast flutters and sings;
He sings to the wide world, and she to her nest,—
In the blue ear of Nature which song is the best?

Now is the high-tide of the year,
And whatever of life hath ebbed away
Comes flooding back, with a ripply cheer,
Into every bare inlet and creek and bay;
Now the heart is so full that a drop overfills it,
We are happy now because God wills it;
No matter how barren the past may have been,
'Tis enough for us now that the leaves are green:
We sail in the warm shade and feel right well
How the sap creeps up and the blossoms swell;
We may shut our eyes, but we can not help knowing
That skies are clear and grass is growing;—
The breeze comes whispering in our ear,
That dandelions are blossoming near,
That maize has sprouted, that streams are flowing,
That the river is bluer than the sky,
That the robin is plastering his house hard by;
And if the breeze kept the good news back,
For other couriers we should not lack;
We could guess it all by yon heifer's lowing,—
And hark! how clear bold chanticleer,
Warned with the new morn of the year,
Tells all in his lusty crowing!

Joy comes, grief goes, we know not how;
Everything is happy now,
Everything is upward striving;
'Tis as easy now for the heart to be true
As for grass to be green or skies to be blue,—
'Tis the natural way of living:
Who knows whither the clouds have fled?
In the unscarred heaven they leave no wake;
And the eyes forget the tears they have shed,
The heart forgets its sorrow and ache;
The soul partakes the season's youth,
And the sulphurous rifts of passion and woe
Lie deep 'neath a silence pure and smooth,
Like burnt-out craters healed with snow."

The Editor with his Young Readers.

Something about Chemistry.....II.

(*Continued from page* 153.)

Almost every thing that has yet been found in the world, has been examined by chemists to ascertain whether it is a *simple* or a *compound* body, and if a compound body, to find what simple bodies or elements enter into its composition. The process by which the chemist examines the composition of any substance is called *analysis*." To analyze a soil, for example, is to separate it into its parts, and find what the parts are, and how much there is of each—to find how much sand, how much lime, how much potash, how much iron, etc., there is in every hundred ounces, or pounds, of the soil. Please remember then, that in chemistry, *analysis* means examining a substance to find what it is made of. Thus: to analyze a piece of cake, we might by a chemical process get out the sugar by itself, the flour by itself, the water, milk, eggs, etc., each by itself. The chemist can even go further, and find what *simple elements* make up the sugar, the flour, etc. Suppose we take a dozen different kinds of cake, and analyze them all. In the first, second, third, indeed in all of them, we should probably find much flour and sugar, and some water, butter or fat, eggs, with a small proportion of spices, etc. With the same few kinds of elements the housewife will make perhaps a hundred kinds of cake, all of which will be different from each other in form or color, or texture, or taste. These differences are produced *by using different proportions of the same ingredients*, (flour, sugar, water, spices, etc.) or by omitting one or more of the spices, or by mixing and baking them in a different manner.—Just so, in the making up of the millions of trees, plants, leaves and flowers, bodies of animals, rocks, soils, etc., only a few simple elements are found. They are put together in different proportions, or combined in a different manner. Indeed, you may gather all the plants that ever grew, all the animals in existence, the great bulk of all the soils we cultivate, all the air and all the water on the earth's surface, and set the chemists to work upon them, or on portions of each, and they will be able to find in them *only about fifteen simple elements!*

Even more wonderful still, over half of the weight of all these substances, including the rocks and soils, will be found to consist of only one single element! Let us now look a little at

THE ELEMENTARY BODIES.—About fifty of the elements are METALS, such as Iron, Manganese, Copper, Lead, Tin, Zinc, Gold, Silver, Platinum, Cobalt, Bismuth, Antimony, Mercury, Sodium, Potassium, Aluminum, and over thirty others which are only found in small quantities. Then we have a few other *elements* which are seen either in solid or liquid form, or both, such as Sulphur or Brimstone, Arsenic, Carbon (or Charcoal), Phosphorus, Chlorine, Iodine, Bromine, etc.—Finally, we have three which can never be *seen*, because when in a pure uncombined state, they are transparent gasses, or air-like substances. The names of these three substances are: OXYGEN, HYDROGEN, and NITROGEN—pronounced Ox'-y-gen, Hy'-dro-gen, and Ni'-tro-gen. These are very important elements, and you should not be afraid of their names, but learn them, and try to understand something about them. We said that when they are *pure*, or not combined with any thing else, they naturally assume a gas or air-like, transparent form. But the first two, Oxygen and Hydrogen, have strong attachments, (are very affectionate,) and they are always found united with one another, or with something else, and then then they may be in a solid form like ice; or in a liquid form like water; or in a gaseous form like the water in its invisible state as it floats unseen in the air.

When one quart of pure *oxygen*, and two quarts of pure *hydrogen* unite, they condense and form a little drop of *water* which is simply a *compound* of these two elements.

When one quart of pure *oxygen* is mixed with four quarts of pure *nitrogen*, they form five quarts of pure *air* which is a mixture of these two elements.

When a little lump of pure black charcoal (*carbon*) is joined with some pure *oxygen* gas, by burning, the two unite and form an air-like, transparent or invisible substance called *carbonic acid*. It is this same compound gas (carbonic acid) that bubbles up in soda water, or in beer; and it is this same air-like substance that swells out in the thousand little holes in light raised bread. The chemist can catch the carbonic acid gas (not air) in the holes of the light bread, and by some of his peculiar processes, he can get a quantity of pure black carbon (charcoal) out of it, and also some pure oxygen.

You now know that water is made up of *oxygen* and *hydrogen*; also, that *iron* is one of the *elements*. Now when you moisten a piece of iron with water, and let it lie awhile, the iron unites with the *oxygen*, taking it away from the *hydrogen*, and forming iron rust, which is a reddish compound made up of iron and oxygen. The chemist calls it "*oxide of iron*," that is, oxygen united to iron. (This oxide of iron is what gives the reddish color to our soils.) But when the iron takes away the oxygen from the hydrogen in the water, the hydrogen does not seem to like to be left alone, and so it grasps hold of some of the nitrogen in the air, and forms another new compound called *ammonia* (harts-horn), which is also a gas or air-like substance, that has a strong pungent odor, such as you perceive in smelling bottles, or in the horse stables, or manure heap, etc. It appears strange that one of the elements of pure water united to one of the elements of pure air, should produce such a strong smelling, choking substance as ammonia; yet such is the case, and this is only one of the ten thousand strange things that chemistry reveals. Still further: the ammonia thus produced by the iron rusting in the water, as fast as it is produced, flies away into the air, and some of it is caught in the little mouths on the leaves of plants, and other portions of it are washed down into the soil by rain and dew, where it is taken up by the roots and carried into the plants, to nourish them. (Our young readers who live on the farm, well know that the best manures or fertilizers to feed plants with, are those which contain most of this pungent ammonia, such as horse-stable manure, Peruvian guano, etc.) Ammonia is produced in a great many other ways, besides the rusting of iron.

Wood contains a good deal of the element *carbon*, or charcoal. A stick heated in a close vessel, or covered up with earth to keep out air, loses its other elements, and we have left a large mass of coal, which is nearly pure carbon. Hard coal, sometimes called stone coal, from its stony hardness, is nearly pure carbon, but not quite so pure as charcoal. When we burn wood, or charcoal, or stone coal, in a stove or grate, the oxygen of the air leaves the nitrogen and unites with the atoms of carbon in the wood or coal, and then we have some of the carbonic acid we told you of above, and this goes off into the chimney unseen, just as it rises from the soda water, or exists in the bread, unseen. After a time the whole of the wood is consumed, as we say; that is, it has been pulled to pieces, and its *elements* have gone off in different forms. Why! a whole cord of wood, or a ton of hard coal, soon escapes through the chimney in its new form, and we are not able to see it go. We see a cloud of smoke, which is only the watery vapor, except when the draft

PRAYER—By A FRENCH ARTIST.—*Engraved for the American Agriculturist.*

"Now I lay Me—"

Surely this lovely picture needs no words of explanation or description. It tells its own simple story of piety and divine grace in the heart. "Our Father which art in Heaven," bows his ear to hear the low sweet voice of the prayer by which the child, in offering its own petitions, bears the mother's heart heavenward in holy aspiration. Ruskin, the great art critic, writing of the original, at one time on exhibition at the Royal Academy, directs attention to "The little bare feet keyed from the cold stone by the garment folded under them, bared of their rough grey stockings, as reverently and surely in God's presence as if the poor cottage floor were the rock of Sinai; the close cap over the sweet, pointed, playful waving hair which the field-winds have tossed and tumbled as they do the long meadow grass in May, and yet have not unsmoothed one wave of its silken balm, nor vexed with rude entangling one fair thread of all that her God numbers day by day. The dear, bowed patient face and hands folded, and the mother's love that clasps them close in a solemn awe, lest they should part or move before her Father's blessing had been given in fullness. Return to it, and still return. It should be the last picture you look at in all the year; carrying the memory of it with you far away through the silence of thatched villages and the voices of the blossoming fields." Sweet will be their slumber, and refreshing as dew from heaven to the ever greatful meadows; and under the influence of this simple confidence in God, of such guileless hearts, their souls will grow in all grace and loveliness, as the meadows respond to the dews, and rains, and sunshine.—We trust there is not one of our dear young readers, who lives a prayerless life; not one who walks upon this beautiful flower-clad earth without often lifting the heart in thankfulness to the Giver of all good; not one that rises in the morning without kneeling to express gratitude for protection and crave divine aid for the right performance of the duties of the day; not one who lies down at night without asking forgiveness for sins and follies, and for the guardian care of the ever-watchful Eye during the night. It is not childish to pray; it is noble, it is manly, it is Christ-like.

---

carries up some unburned charcoal dust which gives a dark color to the smoke. Chemistry tells why so much heat is given out while the carbon is uniting with the oxygen, but perhaps you can not understand that now. The invisible carbonic acid, (made of the carbon of wood, and oxygen of the air) floats off and is gradually absorbed by the leaves and roots of trees and plants, and the carbon again forms new wood. These changes are very interesting, and we shall learn of many more, equally wonderful.

The whole world is full of these changes, this destruction of old compounds, and the formation of new ones; the breaking up of the new compounds again, and the formation of others. All visible changes going on—such as the growth of plants and of our bodies, the burning of fuel, the oxydation of iron ore (which is an iron rust, or oxide of iron) into pure iron and oxygen, the manufacture of soda out of salt, the change of flour to bread, the change of bread and meat and other food into blood, and the changing of blood into lean flesh and fat and bones and hair, etc., the changing of hay and grass into the cow's blood, and the changing of her blood into pure sweet milk, the burning and disappearance of the oil or fluid in the lamp, the changing of old cotton rags into pure sweet sugar, and ten thousand other changes of form and substance—all these are directly due to the destruction of one kind of compound bodies, and the formation of new compound bodies out of the *elements* thus set at liberty.

As we have already told you, there are but few elements, but they are united in an infinite number of ways to produce the multitude of things we see. Yet they do not get mixed up at hap-hazard. These elements are governed by certain laws. They have certain *likes* and *dislikes* among themselves, and they follow their stronger inclinations when allowed to do so freely, and it is on account of these likes and dislikes, (their *affinities* as the chemist calls them,) that they are constantly changing. Now, two or more cling together in one compound body; now one of them flies off to something it likes better, and there is a breaking up of old groups (compounds,) and the formation of new ones entirely different; and so the changes go on. The chemist studies out these attachments among the elements (that is, their affinities), and the circumstances which favor the breaking up of groups, and the production of new ones, and he is thus able to control the *elements* themselves, and cause them to do his bidding. He knows, for example, that soda has *some* liking for the volatile carbonic acid gas, and that it holds it fast, making the compound called cooking soda. But he also knows that the soda likes vinegar better than it does carbonic acid. So he puts some soda into a tumbler of water, and pours in a little vinegar. The soda at once quits its partner carbonic acid, and goes to the vinegar, making a new compound. Then, the carbonic acid, being left alone, comes bubbling up through the water, as if in a rage, and flies off in its own proper gas or air-like form, and flies away in search of something else to join hands with. If there chanced to be on the tumbler some freshly burned lime, the carbonic acid would join it, and then we should have a new compound, a real white chalk.

Chemistry is, indeed, a wonderful study—full of interest, and of great usefulness to every body, and we advise every one of our young readers, at least, to learn all they can about it. We will, as we have time and room, try to give an occasional easy and interesting lesson. Please read over and over again, very carefully, these two lessons already given, and try to understand and remember them.

READ THE CHAPTERS ON CHEMISTRY.—They will require some study and thought, but this should not be an objection. That which costs us nothing, is generally worth little or nothing.—The subject will grow more and more interesting, *if* you understand it *all* as we go along.

VALUABLE RECIPES.—For preserving the complexion, *temperance*; for whitening the hands, *honesty*; to remove stains, *repentance*; to improve the sight, *observation*; to improve the voice, *civility*; to keep away moths, *industry*.

Blessed is that man or woman that can let drop all the bars and flabbies, instead of picking them up and fastening them on to the next passenger. Would we only let the vexing and malicious sayings die, how fast the lacerated and scandal-ridden world would get healed and tranquilized. DR. HUNTINGTON.

A good man, who has seen much of the world, and is not tired of it, says: "The grand essentials to happiness in this life are: *something to do, something to love,* and *something to hope for.*"

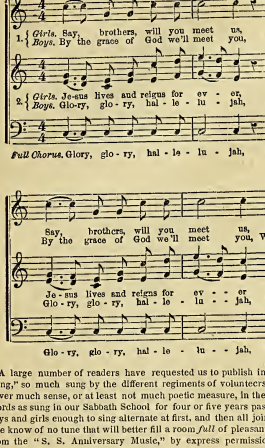
Many a man has missed being a great man, by splitting into two middling ones. Concentrate your energies in one direction if you would make a figure in the world.

If a man cheats you, cease dealing with him; if he is abusive, quit his company; if he slanders you, always take good care to live so that nobody will believe him.

Fame is like an eel—hard to catch, and harder to hold.

BROTHERS, WILL YOU MEET US

Arranged by FRANKLIN H. LUMMUS.

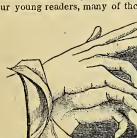


Entered according to act of Congress, in the year 1863, by O. S. SCOFIELD, in the Clerk's Office of the District Court of the United States for the Southern District of New York.

A large number of readers have requested us to publish in the *Agriculturist* what is called the "John Brown Song," so much sung by the different regiments of volunteers. We have heard it frequently, but could never discover much sense, or at least not much poetic measure, in the words. The *tune* itself is given above, but set to the words as sung in our Sabbath School for four or five years past; and very fine music it is, especially when there are boys and girls enough to sing alternate at first, and then all join in a full chorus. All may sing it together, however. We know of no tune that will better fill a room *full* of pleasant melody. [The notes, as above arranged, are taken from the "S. S. Anniversary Music," by express permission of Mr. G. S. Scofield, who owns the copy-right.]

Shadows on the Wall.

The Shadow Pictures already printed have given much pleasure, and so we continue the series. These all require considerable patience and ingenuity, but we think our young readers, many of them at least, will be successful as we have been. "Piggy" is rather hard for some hands, but others will make it very easily. In forming these shadow pictures, the hands should not always be placed so that the light will fall full and square upon them, but a little turn to one side or the other, will often very much change the effect. The Shadow should,



THE GOAT.

PIGGY.

however, ordinarily fall square upon the wall, that is, the lamp must be placed so that the light will fall at right angles to that part of the wall where the shadow is made. Besides, it is not at all necessary to have the fingers close together, by spreading them apart the shadows will often be improved.

THE ARAB'S PRAYER.—"O God, be kind to the wicked; to the good thou hast already been sufficiently kind in making them good."

Always take the part of an absent person who is censured in company, so far as truth and propriety will allow.

Answers to Problems.

Answer to rebus No. 4, April *Agriculturist*, p. 119.—*A wise man sometimes changes his opinions; a fool never.*

Answer to No. 5, April *Agriculturist*, p. 119.—*Our national resources are developed by earnest culture of the arts of peace*—(Hour gnat-eye-on-ale re-sour-ces ar-e developed by ear nest cul chewer pd-fe arts of peas.)

Answer to No. 6.—"*Seest thou a man diligent in his business?—he shall stand before kings; he shall not stand before mean men.* [In the rebus, a man diligent in his business is represented as standing before kings, and again *behind* (not before) men shooting little birds. What meaner men than such are there?]

No. 7. *The Block Puzzle* in April *Agriculturist*, p. 119, is done as shown by the above diagram.

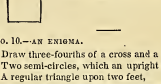
Correct answers to puzzles have been received from: S. Sibly Hopkins, 4 and 6; Jerry M. Cochran, 6; S. and J. F. Mills, 4; R. F. Roberts, 4; Lansing L. Porter, 6 and 7; Oliver Combs, 4 and 6; N. W. Johnson, Jr., 5, 6 and 7; Chas. B. Warkwick, 7; Ida, 4 and 6; Luke Robinson, 7, C. Adams, 5, 6 and 7; Irenæus N. Kneeland, 4, 6 and 7; R. W. Weeks, 4, 5, 6 and 7; F. W. M., 4 and 6; E. H. Park, 4, 6 and 7; Maggie Darling, 6 and 7; Mattie Drennan, 7; Amanda Rogers, 6; Jarvis H. Arnold, 4 and 6; J. M. Garretson, 7; I. R. Smith, 4, 6 and 7; Henry F. Miles, 4, 5, 6 and 7; Katie M. Humphrey, 4, 5 and 6; C. L. and A. C. Selwers, 3; F. C. A., 6; L. Harrison's boys, 7; D. B. Rogers, 7; Simeon H. Batterson, 4, 5, 6, 7.

CONUNDRUMS are often most enjoyed when the answers are given at the same time. Master Frank Fargo writes: "I have a pair of pigeons—why are they like a shiftless farmer? *Ans.* Because they'll prop-a-gate until its fall. When is a farmer like "Old Uncle Ned?" *Ans.* When he loses his hair, (h) (harrow.)"

New Problems.

No. 8. This is another rebus founded on a passage of Scripture;—very easy to guess, we think.

No. 9. *Another Block Puzzle.*—Take twelve pieces of block or card, like the following, four of each kind, and place them together to form a perfect square.



No. 10.—AN ENIGMA.

Draw three-fourths of a cross and a circle next,
Two semi-circles, which an upright meet,
A regular triangle upon two feet,
Two semi-circles and a circle complete,
Which, if well done, the source will show
Of a little "solace," and much harm, too.

The Game of Solitaire.

"Buckeye Boy" sends to the boys who read the *Agriculturist* a puzzle, which is the old game of "Solitaire" played with pegs or checker-men. He directs to check off a square in twenty-five smaller squares or checks, upon a slate, paper, or board, and to place twenty-four buttons, one on each square, except the middle one; then by "jumping" one at a time, in any direction, except cornerwise, and taking off the one jumped over, to remove *all* the buttons except one. The best arrangement for this very pleasant game is with the use of a light piece of board, in which holes are bored, pegs being used instead of buttons. On the under side of the board a piece of broadcloth, or nice leather, may be tacked, to serve as a pocket to hold the pegs. The plan proposed requiring only twenty-four men, is quite simple; but if it is desired by any one to play a harder game, and one requiring more thought, it may be done by adding places for more men.

The Russian Locust War.

Translated for the American Agriculturist, from the German of DR. OTTO UHR.

"Continental papers contained, during the last few years, frightful accounts of the destruction done by the locust. In Bessarabia, these animals covered an area of 128,000 acres with their eggs; in the Chersonesus and Taurie Government, twice that space was occupied. All possible means were resorted to to kill these eggs, such as digging, collecting and burying and burning them, plowing the ground and tramping it hard with horses and cattle. On one piece of land of 1,100 acres near Chotim, not less than 4,400 bushels of locust eggs were collected. About the first of May, when the eggs began to hatch, rollers and harrows were brought into requisition, but all to no avail. Toward the last of July this pest passed beyond Bender on the Dniester, in a width of 8 miles, and in a mass from 7 to 8 inches thick, and crossing the river within 2 days, they spread themselves along the low lands of the opposite shore. Here it was that a battle was fought such as the records of Natural History can show no parallel to—men of all nationalities gathered to defend their homesteads, and in a short time 1,400 men stood in arms against the destroyer. Meanwhile the locust had spread over an extent of 16 square miles. To prevent them from attacking the surrounding fields, deep ditches 24 to 29 miles long were dug, and men placed along these ditches to kill the locusts dropping into them. Others fought them with bush-harrows and brooms in those places where ditches could not be made. Where the ground was clean, hordes of horses and cattle were driven along to crush them. Pickets on horseback were stationed to watch the movements of the enemy breaking through the ranks. Eight days were thus occupied. Three quarters of the locusts were destroyed, when the remainder had completed their last change and became winged insects: on the 9th of July, the first swarms rose into the air and flew in different directions. The battle was not fought in vain. While in the Province of Chersonesus, nearly the whole crop was destroyed, Bessarabia suffered but very little."—*What a lesson for the American farmer!* If we do not have the Egyptian locust, or the large locust, we have certainly other pests liable to become just as great. Not many miles from where we write, we have seen clover fields and Hungarian grass extensively destroyed by the common grasshopper, and the ravages of the Army worms and other insects are fresh in all our memories.

Reports on Crops, May 10, 1862.

(*See General Remarks on page* 168, *and Notes to Crop Reporters on page* 164.)

EXPLANATIONS TO THE READER.

(Full details are given on the Blank Forms furnished to Reporters.)

The First Column gives the principal Counties from which the reports come. In many cases, however, the territory reported from extends over on to adjacent counties, and the figures in reality apply to a larger territory than the county named.

The Second Column gives the number of persons in each county or locality, the average of whose opinions are embraced in the single rows of figures, standing opposite in the same line. In several cases a whole County is represented by an officer of the Agricultural Society, who gives the summary of reports from assistants in each of the towns. *m* indicates that a large but indefinite number of persons joined in making the report.

The Third Column gives the names of the persons who received and distributed blanks, and collected and forwarded returns.

☞ *In all the reports the numeral* **10** *is taken as the* UNIT *or average for comparison*, thus:

Column A—10 means that the weather for a month previous to the date of the report was about as good as the average for other years, that is for Winter crops and for general farm operations. The state of the weather as it has affected the grass crop, is not taken into account. Figures above or below **10** indicate the comparative goodness or badness of the weather.

Columns—B—E—H—In these **10** indicates that the amount of surface growing is about the same as *last year*. Each figure (or unit) above **10** means a tenth more of surface. and each unit below **10**, means one-tenth less. Thus, **5** means one-half of average surface—**15** means one and a half—**20** means double, and so on.

Columns C—F—I—L—N—P—S—In these columns **10** means that the average surface sown or planted or growing is about the same as the average for five years past. Each unit above or below **10** stands for an increase or decrease of one-tenth in the surface.

Columns D—G—K—M—O—R—T—U—V—In these columns **10** means that the *condition* and *prospect* on May 10th indicated an *average yield per acre*. Here also each unit above or below ten indicates the prospect of a yield a tenth above or a tenth below the average ; thus, a half crop is indicated by **5**—a double crop by **20.** Some report fruit prospects at **100** to **300**, meaning that the promise is for ten to thirty times the average crop in the localities named.

Blanks in a column indicate that little or none of the crop is grown, or that it is too early to report upon it, or that the reporter could not estimate satisfactorily to himself.

Reports on Sorghum—Maple Sugar—Barley—Flax, etc.

With the preceding general reports, came estimates of several other crops, of which the following is a summary:

Sorghum.—We have compiled the reports from *Thirty* counties in the Western or Northwestern States, including three counties in Pennsylvania, from which the estimates indicate that the surface planted this year will be **2 3-4** times greater than for any previous year.

Maple Sugar.—The reports from Vermont, New-York, and Ohio, range from less than half, to four times the usual amount of maple sugar made this year. The *average* of all the reports indicate that the product has been one-fourth greater than usual, but there are too few figures to give an estimate for the whole country.

Barley.—Reports received from only 25 counties, in New-York and at the West. These indicate that an average of *one-fourth above* the usual crop, is being sown this year. A larger number of reports are needed, however, to make out a ratio for the whole country. We shall doubtless have this before the harvest season.

Flax.—A few reports from Flax-growing regions indicate a large sowing of this crop. In Cedar County, Iowa, Mr. May, reports a double surface. In Newton County, Ind., Mr. E. G. Smith, reports four times the usual surface. In Benton County, Ind., Mr. D. Campbell, reports five times the usual surface. In other localities the estimates range from one-fifth less to a double surface.

Other Crops.—We have other scattering reports on Peas, Beans, Hops, Onions, Sweet Potatoes, Tobacco, Grapes, etc., etc., but not enough to form any estimate for the country at large.

Average Price of Potatoes, Carrots and Rutabagas for Every Month in the Year Past.

A year ago, (p. 204,) Mr. Geo. W. Walker, Pier 30, East River, furnished an interesting table, showing the average price of potatoes for seven years past. We are now enabled to compile from his figures the following table, which has a still more practical value:

	POTATOES PER BARREL.				
	Mercers.	*Peach-blows.*	*Common kinds.*	*Carrots, pr. bbl.*	*Rutabaga turnips pr. bbl.*
April	$2 18¾	$1 81¼	$1 43¾	$......	$......
May	2 37½	2 18¾	1 81¼	1 37½	50
June	1 56¼	1 56¼	1 25	1 50	62
July	1 25 1 56¼*	1 12½	81¼ 1 81¼*	none.	1 04*
August	1 62½	none.	1 43¾	1 87½*	68
Septem'r.	1 62½	1 50*	1 12½	1 50	75
October	1 43¾	1 25	1 06¼	1 00	88
Novem'r.	1 93¾	1 53	1 31¼	90	68
Decem'r.	2 18¾	1 87½	1 50	82	82
January	2 37½	1 93¾	1 56¼	90	90
February	2 34	1 93¾	1 68¾	82	1 00
March	2 62	2 12	1 81¼	82	94
April				1 00	1 00

(*) Indicates appearance of new crop in market.

Owing to the stoppage of shipments of merchandise to ports south of the Delaware, and down the Mississippi River, large quantities of produce came from the West and some potatoes were sold as low as 50c. a bbl. in July.

Carrots and Turnips have been in good demand this year, the desiccating companies using large quantities to supply the army. They use about 500 bbls. a week, and have kept the market unusually steady for soup vegetables.

Market Review, Prices, etc.

AMERICAN AGRICULTURIST OFFICE,
New-York, Monday Morning, May 19, 1862.

The condensed but very comprehensive tables, below, show at a glance the amount of the transactions in the flour and grain markets. It will be noted that there has been a large increase in the amount of receipts, as compared with the previous month, in every thing but Barley. The increased receipts of the principal articles, Flour, Wheat, and Corn, are very marked, particularly in Wheat, the receipts of which have reached 518,000 bushels during 25 business days, against only 107,370 for 26 days last month. The sales of Wheat, Flour, and Barley, have also been much larger. As compared with the same period last year, however, the transactions have been less this year, especially as regards wheat. This is mainly due to the later opening of the Canals, than usual. Tables 4 to 8, give interesting statistics of the condition of the grain trade at the principal Western inland ports. At Chicago, the receipts of Wheat and Corn have been smaller this year, while the stocks on hand, on the 12th of May, the date of our latest reports, are in marked excess. .... When our previous report closed, there was a sharp upward turn in prices, which promised to continue, and the advance went on for a few days, until nearly the highest figures of the year were reached, but another downward turn again occurred, which has continued until now, and holders of large stocks of breadstuffs are apparently almost panic stricken. The causes of this decline have been mainly the same as referred to last month, added to which has been the material advance in ocean freights. So high is the charge for ship room now, that there is little encouragement to exporters to purchase for foreign markets in their present depressed condition, except at very low rates. Perhaps as a just retribution for their course at the beginning of our war, and their manifest desire to see our country crippled and divided, England and France are now suffering financially even more than ourselves, from the effects of the war. Millions of their inhabitants who have hitherto lived by manufacturing American Cotton, are now out of employment, and unable to purchase the better class of breadstuffs, while the economy practised in this country very greatly depresses their sales of manufactured articles. Recently we have many rumors that England and France will attempt to interfere with the war here in order to obtain a supply of cotton. The foolishness of such a course would seem to be evident. Cotton will do them no good, if they can not sell their manufactures, which they will be unable to do if by "intervention" here they break up their trade with us. America is the largest, the principal market for English and French manufactures, but the least attempt to interfere with our domestic affairs would close our ports against them.—Now we send abroad, from the West, corn worth 10 to 15 cents a bushel there, for which the foreign consumer pays 80c. to 90c., owing to the cost of transportation. It will not require much foreign jealousy and interference to lead the people of this country to inquire whether it may not be quite as well to shut out imports by a prohibitory tariff, and do our own manufacturing at the west where food is plenty and cheap, and where coal and the raw materials—iron, cotton and wool—are at hand. We have, from principle, always been opposed to "protective" tariffs, but the present course of events strongly indicates the *practical* utility of consuming our agricultural products in manufactures at home, and thus save the great cost of transportation. But, except as the subject directly affects the agricultural interest of our country, we shall not open our columns to the discussion of tariffs......So far as *present* rates are concerned, the immediate prospects of our farmers for high prices are not so favorable as we had hoped for, and as we fully expected to report at this date. The extremely favorable weather abroad, and the distress in the manufacturing districts, continue to depress the foreign breadstuff markets. The crop prospects in this country are on the whole very favorable. (See the extended reports given elsewhere in this paper.) The late opening of the Spring, has retarded Spring sowing and planting, but the effect of the weather upon Winter grain crops, and upon fruit, has been of the most satisfactory character. The very unusual absence of frost after warm weather finally set in, has been in the highest degree advantageous to crops. With no untoward weather hereafter, our next harvest will be one of the largest yet known, that is for Winter and Spring wheat, for grass, and for fruit.....COTTON advanced considerably, subsequent to our last report, but closes with a downward tendency....Provisions have been quoted active, but at unsettled rates....Hog products (pork, hams, bacon, and lard,) close at declining rates....Beef, Butter, and Cheese, are firmly held; old Butter is scarce, among wholesale dealers....Tobacco has recently been in good request at very full prices....Wool has been more sought after, and holders have exhibited increased firmness.... Hay and Hops have been in fair demand at steady rates.. The transactions in other agricultural products have been on a moderate scale. The table of prices show the changes and the present rates.

CURRENT WHOLESALE PRICES.

N. Y. Live Stock Markets.—THE CATTLE MARKETS have been over-supplied, the past month, the average receipts being 4,469 per week, or a total of 3,600 head more than for the previous month. Graziers have been buying for Spring and Summer feeding, and Government agents have taken a few hundred each week for the Navy, and for shipping to southern ports. But with these aids it has been difficult to sell all the cattle, during this season of cheap shad and eggs, with a full supply of early fresh vegetables. At the last general market, May 13th, with 4,800 cattle on sale, prices ruled low. The best bullocks sold at 8c.@8½c. ₰ lb. estimated dressed weight; fair steers 7½c.; poor 6c.@7c.; with an average of 7¾c. for all sold, most of which were of good quality. Market dragging. The indications to-day are for a smaller supply and higher prices this week.

Veal Calves.—Receipts for the past month, number 9,300 per week, not including large numbers which are sold direct from the river barges. The market has been over-stocked each week and prices have ruled low at the pretty uniform rates of 5c. per lb. live weight for the best; 4c.@4½c. for good, and 2½c.@3½c. for poor; many young calves are sold by the head at $1 and less.

Sheep and Lambs.—Now that the fleeces are all taken off, receipts are on the increase, though still moderate. The average for a month past has been 5,817 per week. Sheep bring $3 to $5 per head, equivalent to 4c.@4¾c. ₰ lb. live weight, while Spring lambs of 55 to 65 lbs. live weight, sell at 7½c.@8c. ₰ lb., or $4@$5½ each.

Live Hogs.—Receipts about the same as last month, or 11,997 per week, and prices ½c. lower than 4 weeks ago, with a slow over-stocked market. Prime heavy corn-fed hogs are the only ones which sell readily. They are worth 3½c.@4¾c. ₰ lb. live weight, and still-fed hogs, 3¼c.@3½c. Light and poor hogs, whether corn-fed or otherwise, can scarcely be sold at 2¾c.@3¼c. ₰ lb.

The Weather, for most of the month past, has been favorable for farm operations, and the present prospects indicate a fruitful season, especially so for the tree fruits, which have thus far been less affected by frosts than during any previous Spring for several years past. The season is now about one week later than last year, but probably none the less favorable on that account, except so far as the late opening of the ground hindered getting in the earlier crops. The ground is rather dry under two weeks of warm sunshine, with scarcely rain enough to lay the dust, and at this date some are fearing an early drouth. OUR DAILY NOTES, condensed, read: *April* 19 to 22, rain storm, soaking the ground thoroughly (2½ inches,)—23 to 27, clear, warm days; peach trees blooming in city yards—28, 29, cloudy, with light rain—30, clear, warm.——*May* 1, 2, heavy N. E. rain storm, flooding streams—3, 4, clear, warm—5, thunder shower P. M.—6, wind and showers, (Stuyvesant pear tree in bloom, 12 days later than last season)—7, wind and clouds—8 to 13, clear, fine growing weather; slight shower night of 13th. ground dry—14 to 18, mostly warm, clear weather; ground getting quite dry—19, cloudy, with light showers—20, cloudy—21, fine rain.

Rain Fall.—From the 15th of April, to the 15th of May, there were **3.95** inches of rain, the most of which fell on the 1st and 2d of May.

Advertisements.

Advertisements to be sure of insertion must be received at latest by the 15th of the preceding month.

TERMS—(invariably cash before insertion):

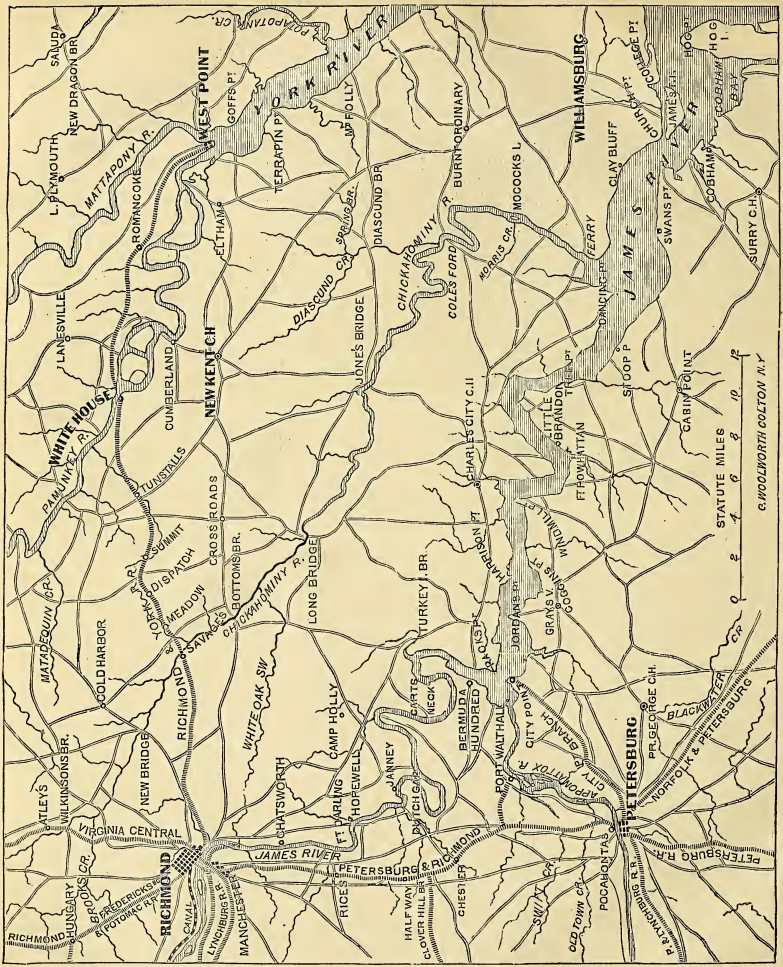
IRON RAILINGS, VERANDAHS, BALCONIES, GUARDS, and *IRON FURNITURE* of every description. Illustrated Catalogues mailed on receipt of four 3-cent stamps.
HUTCHINSON & WICKERSHAM,
259 Canal-st., near Broadway, New-York.



RICHMOND, Va., AND VICINITY.—The above accurate map, shows a section of great interest just now. It is on a scale of *five miles to the inch*. The Union forces, under General McClellan, are reported to-day (May 21,) to have advanced towards Richmond, as far as the Chickahominy River, at Bottom's Bridge, New Bridge, etc. Fort Darling, on James River, 8 miles below Richmond, was reached by the Monitor and other gun-boats last week. Our map last month, showed the whole country from Richmond to Yorktown, Fortress Monroe, etc.

WANTED FOR CASH.—A farm in a good location, which must have been in use, at least partially. Send offers with description, price, etc., addressed "S.," American Agriculturist, 41 Park Row, New-York.

L. I. POTTERY—Drain pipes for water and sewerage, land tile for agr'l drainage, chimney tops, garden vases, flower pots, fire bricks, &c. E. H. QUINN, 278 Pearl-st., N. Y.

EVERY MAN HIS OWN PRINTER.—Portable Printing offices for business men and others, adapted to the printing of Circulars, Labels, Cards, &c. Send for a Circular. ADAMS PRESS CO., 31 Park Row, N. Y.

Circulation of the Agriculturist.

Beyond all doubt or controversy, the circulation of the American Agriculturist to regular subscribers, is many thousands greater than that of any other Agricultural or Horticultural Journal in the World, no matter what its character, or time or place of issue. The publisher is ready at all times to substantiate this statement by comparing books.

SORGHUM SEED.—Carefully cultivated and absolutely pure. Price $4.00 per bushel in bags or bbls, free of drayage.

SORGHUM GROWERS' MANUAL—a practical Treatise, addressed to cultivators of the northern cane. Mailed for 25 cts.

ILLUSTRATED CATALOGUE of Cane Mills and sugar making apparatus *sent free*. WM. H. CLARK,
Manufacturer of Cane Mills, &c., 122 Main-St., Cincinnati, O.

TO ANY ONE IN THE U. S. WHO WILL send us $1 in coin, we will return per same conveyance a package of seeds of the giant fir of Oregon. These seeds germinate readily, and the tree is one of the most highly ornamental in the world. W. W. BRISTOW, P. M. Pleasant Hill, Oregon.

BOOKS FOR FARMERS AND OTHERS.

[Any of the following books can be obtained at the office of the *Agriculturist* at the prices named, or they will be forwarded by mail, *post paid*, on receipt of the price. Other books not named in the list will be procured and sent to subscribers when desired, if the price be forwarded. All of these books may well be procured by any one making up a library. Those we esteem specially valuable, are marked with a *.]

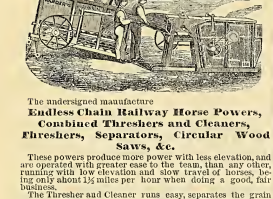
Tools of every description for Farm and Garden use. Field, Garden, and Flower Seeds, Fertilizers, &c., &c.

R. H. ALLEN & CO., Successors to R. L. Allen.

THE BEST THRESHING MACHINE.



The undersigned manufacture

Endless Chain Railway Horse Powers, Combined Threshers and Cleaners, Threshers, Separators, Circular Wood Saws, &c.

These powers produce more power with less elevation, and are operated with greater ease to the team, than any other, running with low elevation and slow travel of horses, being only about 1¾ miles per hour when doing a good, fair business.

The Thresher and Cleaner runs easy, separates the grain perfectly clean from the straw, cleans equal to any fanning mill, is capable of doing a larger business without waste or clogging, than any other two-horse cleaner before the public. For further particulars address R. & M. HARDER,
Cobleskill, Schoharie Co., N. Y.

Ingersoll's Cheap Hand Power Presses for Baling

HAY, STRAW, COTTON, WOOL, RAGS,

MOSS, BROOM CORN, HAIR, HIDES, &c.

These Presses are made for any size or weight of bale required, and delivered on ship board in New-York. Farmers and others wanting such machines are invited to write for Catalogue containing full information.

PRICE OF MACHINES:

No. 1, Press for HAY, &c., weight of bale 150 to 300 lbs., $50.00
No. 2, do. do. do. do. 250 to 300 lbs., 75.00
RAGS, BROOM CORN, &c. 85.00
Weight of No. 1 Press, 850 lbs.; No. 2, 1500 lbs.

Over 1000 of these machines are now in use, many of which are extensively used for baling Hay, etc., for the Army. Address **INGERSOLL & DOUGHERTY,**
GREENPOINT, N. Y.

BOARDMAN, GRAY & CO.,
PIANOS,

THE BEST AND MOST DURABLE.

Our large, elegant, and superior Pianos of 7 and 7¼ octaves at low prices for cash.

Howard's NEW MOWER and MOWER AND REAPER FOR 1862.

Four sizes—cheap—durable—light draft—free from clogging, and perfect in their operations either in cutting grain or grass.

Send for Circular giving full description and cuts of each machine.

N.B.—I have leased of A. W. Morse the right to use his patented lever or holster, by which the finger-bar of a mowing machine is raised or lowered, therefore farmers will not be subject to prosecution by said Morse in using this valuable invention. Address R. L. HOWARD,
Buffalo, N. Y.

NEW-YORK STATE AGRICULTURAL WORKS.

WHEELER, MELICK & CO., Proprietors.

ALBANY, N. Y.,
MANUFACTURE WHEELER'S PATENT

Railway Chain Horse Powers,
FOR ONE AND TWO HORSES;

Lawrence & Gould Patent Railway Chain Horse Powers,
FOR ONE, TWO, AND THREE HORSES;
PLANTATION OR LEVER HORSE POWER,
FOUR HORSE OR SIX MULE GEAR;

WHEELER'S PATENT COMBINED THRESHER AND CLEANER.

No. 1, 30 inch and No. 2, 26 inch Cylinder;
BARGER'S PATENT CLEANING ATTACHMENT,
AS SHOWN IN CUT BELOW.

This Cleaning Attachment can be used with any ordinary Thresher, over or undershot, dispensing with the Shaker or Separator, and takes no more power to drive it than to drive the Shaker—to which we call the attention of farmers having Threshers without Cleaners, and can be attached without the aid of a mechanic.

OVERSHOT THRESHERS AND SEPARATORS,

And other Farming Machines for Horse Power use.

Circulars containing List of Prices, and full description and Cuts of each Machine, with statements of their capacity for work, will, on application, be sent by mail, free.

☞ LIBERAL DISCOUNTS MADE TO DEALERS.

Responsible Agents are wanted in sections where we have none. Address

WHEELER, MELICK & CO., Albany, N. Y.

Our Conical Mills

ARE PREFERABLE TO Flat Mills for the following, and other, reasons:

1st. They make BETTER FLOUR.
2d. Do as MUCH WORK, with 30 per cent. LESS power.
3d. Require LESS ATTENTION than ANY Flat-stone Mill.
4th. Do not injure by running empty.
5th. The FEED is in proportion to the SPEED of the Mill.
6th. Are easier set to work than Flat Mills.
7th. Can be kept in order by a common hand.
8th. Unsteady motion does not affect them much.
9th. Can be driven by any Two-Horse power.
10th. We WARRANT them in all these particulars.

PRICE OF MILL, ready to run, $120. Also, the BEST Iron Mills, $10 and $50. Send for Circular—free to all.

EXCELSIOR
BURR STONE MILLS.

(FOR FARMERS AND MILLERS.)
AND
ANTI-FRICTION
HORSE POWERS.

TOOK TEN FIRST PREMIUMS at WESTERN STATE FAIRS last year, and are justly considered superior to all others.

The Mill may be driven by *horse, water, or steam power*, does its work as well as the flat stone mills in milling establishments, and requires but *one-half the power* to drive the largest sizes. They are very compact, perfectly simple, and for farm use will last *thirty years*, and cost *nothing* for repairs.

THE HORSE-POWER,

Has proved itself to be the best ever invented. The friction is reduced by IRON BALLS, so arranged in all the bearings, that the whole weight of the castings runs upon them. THREE POUNDS DRAUGHT, at the end of a four-feet lever, will keep the power in motion! thus permitting the ENTIRE STRENGTH of the horses to be used on the machine to be driven. ONE HORSE will do as much work on this power, as TWO on the endless Chain Power. IT IS PORTABLE, and may be used in THE FIELD as well as in the house. More than TWENTY-FIVE PER CENT of horse flesh is saved over ANY OTHER POWER IN USE. It is simple in construction, and not liable to get out of order.

Price of Power for 1 to 4 horses $125
Price of Power for 1 to 8 horses 175

The $125 POWER WILL DRIVE ANY THRESHING MACHINE.

EVERY MACHINE IS GUARANTEED TO GIVE SATISFACTION, OR THE MONEY WILL BE REFUNDED.

We have completed an arrangement with the Western Transportation Co., by which they agree to deliver our Mills and Powers at PORTS ON LAKE ERIE AT 25 CTS. PER 100 lbs.; MILWAUKEE, CHICAGO, AND INTERMEDIATE PORTS AT 30C.; SHEBOYGAN AND GREEN BAY AT 35C, and to TWO RIVERS, MANITOWOC, AND PORT WASHINGTON, WIS., AT 40C. PER 100 lbs.

Liberal discount to agents, State, County, and Shop Rights for sale. For testimonials and further information see May number of this paper, or send stamp for Illustrated Circulars to BENNET BROTHERS,
45 and 64 Greene-st., New-York.

WOODRUFF'S IMPROVED WEATHER INDICATOR.

While in this age of invention and progress, our American Farmers have seized with avidity almost every invention and improvement of husbandry that Art or Science could bring to their aid, one of the most important auxiliaries —the Barometer—has been almost entirely overlooked. This has arisen partly from a want of knowledge of its value and importance, but principally because the peculiar delicacy of construction, and high cost of the instrument have made it unavailable to the masses. In this instrument these objections have been entirely obviated. While its simplicity of construction, and scientific arrangement, render it perfectly portable and accurate, its cost is so low as to place it within the means of all. Indicating with unerring certainty coming changes in the weather, it also affords a simple and accurate medium for measuring hights, while the accompanying Thermometer gives the temperature. The Scientific American, Profs. Williams, Carr, Holmes, Douglass, and a host of public journals and scientific men, recommend it as the *Agricultural Barometer, par excellence*. Profs. Henry, Hackley, Maury, Drs. Arnot and Dick, have computed that an annual saving of ten per cent. on all crops might be made by its use, thus affording an annual saving of over fifty million dollars to the farmers of the United States. It is simple, durable, accurate, perfectly portable, and very cheap; is nicely finished, and affords a very beautiful and ornamental piece of furniture, some of the carved cases being very elegant. We give below a brief description of it, from the accompanying cut, in which the cistern is seen divided to show its construction. The cistern, *A*, is of cast iron—cast with two compartments—partly filled with mercury. The tube *C*, filled with mercury, is sealed into the cistern, *A*, and being placed upright, the air is admitted by turning back the screw, *D*, which has a flat place filed in its side near the outer end, where air can pass through the outer wall, when the mercury takes its level, and it is in working condition. To make it portable, turn it upon its side, when the spare mercury runs from *B* to *A*, filling tube and cistern, *A*, full—turn in the screw, and it is shut into *A* perfectly solid, and may be thrown about with impunity, or carried by Railroad or Stage Express all over the world in safety.

We claim for this instrument that while it possesses ALL THE INTRINSIC MERIT of other Barometers, it has several peculiar advantages possessed by NO OTHER, while its construction is such as to avoid the objections to which all other instruments are more or less subject. Among its peculiar merits are:

1st. Its accuracy, being a Mercurial Cistern Barometer, and constructed on strictly scientific principles. It has stood the severest tests of a great number of scientific men, and is amply recommended by eminent scientific authorities who had previously discarded and condemned the Aneroid and other ordinary cheap Barometers. For evidence of this we refer to the U. S. Coast Survey, Smithsonian Institute, and other eminent scientific authorities whose certificates we have.

2d. Its cheapness. While possessing intrinsic merits possessed by none other, its price is lower than any other reliable Barometer.

3d. It is perfectly and entirely portable, and can be expressed by stage or railroad to any part of the country without injury. THERE IS NO OTHER PERFECTLY PORTABLE BAROMETER.

4th. Its thorough construction and perfect simplicity make it the most durable and perfect Barometer ever invented, and renders it impossible to injure or get it out of order, except by gross carelessness or design.

5th. It is unaffected by changes in temperature, which can be said of NO OTHER Barometer.

6th. Its beautiful finish and tasteful design render it a heautiful parlor or library ornament, while it affords a never failing study of interest to the man of leisure, cultivation and refinement, and a sure and reliable indicator of the coming weather, to all whose interests are affected by atmospheric changes.

PREMIUMS

Have been awarded it by the New-York, Vermont, Michigan, and U. S. Agricultural Societies over all competitors.

☞ Agents wanted everywhere. Exclusive agencies given to

CHARLES WILDER,
Peterboro', New-Hampshire.

THERMOMETERS and HYDROMETERS furnished.

LIFE INSURANCE.

MANHATTAN LIFE INSURANCE CO.,

No. 31 Nassau Street, New York,

Opposite the Post-Office.

CASH CAPITAL AND ACCUMULATION OVER

$1,200,000.

CLAIMS PAID, $650,000.

DIVIDENDS TO POLICY HOLDERS, $340,000.

This Company being conducted by a Board or Directors owning STOCK in the Company, has the advantage of the stock plan of management, with the mutual feature of sharing the profits of the business, without being liable to assessments. The triennial dividend of profits of this Company has resulted in a bonus or addition to the policy of more than fifty per cent. on the whole premium paid.

The dividends are paid in the life time of the assured, thus aiding them to pay future premiums.

Premiums may be paid annually, semi-annually, or quarterly, when the policy is for life, and the annual premium amounts to $40 or over. From 40 to 50 per cent. may be paid by notes.

Persons insured may visit Europe in first-class vessels, without extra charge, at all seasons of the year.

HENRY STOKES, President.

C. Y. WEMPLE, Secretary.
J. L. HALSEY, Assistant Secretary.
S. N. STEBBINS, Actuary.

Prospectus, and all necessary information, may be obtained at the office or any of the agencies in the principal towns.

SHOW AND SALE OF SOUTH DOWN SHEEP.

No dark colored queens sent out from our Apiary.
BAKER & TAYLOR, Ruinerville, Bucks Co., Pa.

The Great American Pump.

Three years unbounded success—prices reduced—the best cistern, well, sinking, house, and fire pump; will not rust, will not freeze; throws 75 feet by hand—raises from all depths, forces to all distances and heights—air and water tight. Send for drawings and prices to JAMES M. EDNEY,
493½ Broadway, New-York.

RUSSIA OR BASS MATS, SELECTED EXpressly for bedding stock; GUNNY BAGS, TWINES, HAY ROPES, &c., suitable for Nursery purposes, for sale in lots to suit by D. B. MANWARING,
Importer, 248 Front-st., New-York.

TEETH

UPON ALLEN'S SYSTEM

CAN BE OBTAINED AT

22 Bond-st., New-York.

By this method the TEETH, GUMS, ROOF, and EDGE of the MOUTH are all truthfully represented, reflecting those delicate tints, shades, and forms familiar to the natural organs, thus concealing from the observer the human agency in forming them. This we do positively accomplish, as evidenced by our numerous patrons. The natural expression of the mouth, and original contour of the face can also be restored, which frequently obliterates the waning cheek.

A descriptive pamphlet may be obtained by addressing DRS. J. ALLEN & SON, as above.

SOLAR MATCHES,

Without Sulphur

Or smell when burning, are what every family ought to use who study real economy and their health. Much more reliable than, and as cheap as, the suffocating sulphur matches. Patented and awarded the silver medal at the late Fair of the Institute. Rights to manufacture and sell under the patent for sale. Send for Circular to the **SOLAR MATCH CO.,**
101 and 103 Beekman-st., New-York.

THE GOLDEN RULE.

"Be unto others just and true,
As you'd have others he to you."

Those who buy Pyle's Saleratus, Cream Tartar and O. K. Soap, can depend upon having the best articles of the kind in use. The goods are put up full weight, in exact accordance with the representations on labels. Give them a trial. Sold by grocers everywhere. Manufactured by

JAMES PYLE.
Cor. Washington and Franklin Sts., New-York.

Grover & Baker's CELEBRATED NOISELESS SEWING MACHINES.

FOR FAMILY AND MANUFACTURING USE.
495 BROADWAY, NEW-YORK.

THE GROVER AND BAKER S. M. CO., now offer, in addition to their splendid stock of Machines making the celebrated GROVER & BAKER STITCH, NEW, and superior SHUTTLE, or "LOCK-STITCH" MACHINES, adapted to all varieties of sewing. Much more *Simple, Durable, Noiseless and Perfect* than any "lock-stitch" machines heretofore in use.

"Grover & Baker's is the best."—*Am. Agriculturist.*

FOR SEWING MACHINES.

JONAS BROOK & BROTHERS' PRIZE MEDAL SPOOL COTTON,

WHITE, BLACK, AND COLORED.

200 or **500** yard spools.

For MACHINES, use BROOK'S PATENT GLACE for upper thread, and BROOK'S SEA CORD for TICKET for under thread. Sold by all first class dealers in city and country; also in cases of 100 dozen each, assorted numbers, by WM. HENRY SMITH, Sole Agent, 56 Vesey-st., New-York.

SOMETHING NEW.—Dr. Brown's Patent Baby Tending Machine. The greatest labor saving, health-preserving and pleasure-giving invention ever made; saves from $100 to $500 per year in any family where there is a baby; costing from $5 to $10. Call and see it. Send for cut and circular, containing 20 engravings, illustrating all its shapes, giving prices, etc. Its motion is perfectly charming. Address DR. J. SILAS BROWN, No. 546 Broadway, N.Y.

The Nonpareil WASHING MACHINE.

Is the only reliable one in use. Send for free Circular to OAKLEY & KEATING, 73 South-st., New-York.

For sale, State Rights to manufacture and vend the machine.

ARTIFICIAL LEGS,

LIMBS, SELPHO'S PATENT,

Substitutes for lost limbs, 516 Broadway. Send for a Circular.

A Slight Cold, Cough, Hoarseness, or Sore Throat, which might be checked with a simple remedy, if neglected, often terminates seriously. Few are aware of the importance of stopping a Cough or Slight Cold in its first stage; that which in the beginning would yield to a mild remedy, if not attended to, soon attacks the lungs.

Brown's Bronchial Troches were first introduced eleven years ago. It has been proved that they are the best article before the public for Coughs, Colds, Bronchitis, Asthma, Catarrh, the Hacking Cough in Consumption, and numerous affections of the Throat, giving immediate relief.

Public Speakers and Singers, *will find them effectual for clearing and strengthening the voice.*

Sold by all Druggists and Dealers in Medicine, at 25 cents per box.

GENUINE

SUPER-PHOSPHATE OF LIME,

Manufactured from **Raw Bones,** dissolved in *Sulphuric Acid*, with a few hundred millions, of *$40 per ton*, by

A. LISTER & BROTHER, Tarrytown, N.Y.

(For results of the past season see *American Agriculturist*, for August, 1861, page 262.)

We guarantee every ton of our manufacture to be of uniform quality, and invite trials or chemical analysis.

We also manufacture from RAW, (OR UNDISSOLVED,) BONES, the fine, medium, and coarse ground **Bone Manure,** for lasting effects, and the finely ground **Bone** for all kinds of farm crops. The coarse ground is particularly valuable for *Fruit Trees* and *Grape Vines*, which require a constant and lasting source of nourishment.

For sale in large and small quantities by
A. LISTER & BROTHER, Tarrytown, N. Y.
and their agent, F. LANGMAN, 159 Water-st., New-York.

PERUVIAN GUANO.—CHAPMAN & VAN WYCK, No. 3 Atlantic-st. (corner of Furman), Brooklyn, N. Y., furnish Peruvian Guano, direct from the government agents, in large and small quantities.

Refer to Baird Brothers, 37 Williams-st., New-York,
Ex-Gov. John A. King, Jamaica, L. I.

Strawberry Show

AT THE

OFFICE OF THE AGRICULTURIST,

June 20th and 21st, 1862.

$50 IN PRIZES.

The Proprietor of the *Agriculturist* invites Strawberry Raisers, of this vicinity and elsewhere, to make an exhibition of their choice fruit on Friday and Saturday, June 20th and 21st, in the spacious Office of the *American Agriculturist*; and to give zest to the exhibition, offers the following

PRIZES:

For the largest number of most approved varieties, (one plat each).....varieties.....	$10
Second prize	5
Third prize	3
For the best dish of market berries, (two quarts of one variety—it will be very desirable to show plants with fruit, in addition)	5
For the best dish of the best berries for general cultivation, (two quarts one variety).....	5
For second and third best.....	$3, $2
For the largest three berries of one variety, (weight and size both being considered).....	3
For the best New Seedling.....	3
For the best quart of White Strawberries	2
For the best quart Scarlet Strawberries (one quart).....	2
For the best quart Triomphe de Gand.....	1
For the best quart Wilson's Albany.....	1
For the best quart Hovey's Seedling.....	1
For the best quart Hovey's Seedling.....	1
For the best quart Victoria.....	1
For the best quart Jenny Lind.....	1
For the best quart Vicomtesse Hericart de Thury...	1

The berries to come in competition for the premiums must be upon the tables as early as 10 A. M.* on Friday, June 20th, and each specimen must be correctly labeled. The Awarding Committee will attend to their duties at 11 A. M.—at which hour the exhibition will open. When the premiums are awarded, the *names, places of residence* and of *business* of the exhibitors will be placed upon the specimens, and the prize samples properly designated.

It is particularly requested that persons intending to exhibit fruit announce, *if possible*, about the number of samples they intend to show, some days before hand, in order that we may provide suitable space for them.

The fruit will be subject to the order of the exhibitors at 1 P. M., except the best, if they choose to retain it.

* Exhibitors living at a distance, whose fruit previously announced, can not arrive so as to be on the tables punctually at 10 o'clock, will be allowed a reasonable margin in the judgment of the committee.

An American Exhibition

OF

Pumpkins, Squashes, and Ornamental Gourds.

There will be a Public Exhibition of **Pumpkins, Squashes, and Ornamental Gourds,** at the office of the *American Agriculturist*, 41 Park Row, New York City, opening on Wednesday, Nov. 5th, 1862, at which the following prizes will be paid by the Publisher, upon the official award of competent Committees.

CASH PREMIUMS.

I.	For the *Heaviest* Pumpkin or Squash...	$20.00
II.	For the 2d do. do.	10.00
III.	For the 3d do. do.	5.00
IV.	For the Best do. do. for cooking..	10.00
V.	For the 2nd Best do. do.	5.00
VI.	For the largest yield on a single Vine*....	10.00
VII.	For the 2nd do. do. *....	5.00
VIII.	For the largest and finest collection of Fancy or Ornamental Gourds*.....	10.00
IX.	For the 2nd do. do. *....	5.00

* All to be grown by one person and to be accompanied by an affirmed statement from the grower, and two disinterested persons who assist in gathering the specimens.

Note 1.—The specimens receiving the Prizes will remain on Public Exhibition at the pleasure of the Publisher who offers the prizes. The other specimens will be subject to the order of the exhibitors, or they will be sold at Auction or otherwise disposed of, for their benefit.

Note 2.—All Exhibitors must notify us of their intentions by Oct. 10th, and deliver specimens for competition on or before Nov. 3d. Specimens to be delivered free of charge.

Bound Volumes—Binding—Covers.

We have complete sets of Vols. 16, 17, 18, 19, and 20, both unbound, and bound very neatly in neat covers with gilt lettered backs.

PRICES AT THE OFFICE.

Volumes 16, 17, 18, 19, and 20, *unbound*.....$1.00 each.
Volumes 16, 17, 18, 19, and 20, *bound*.....$1.50 each.

PRICES WHEN SENT POSTPAID BY MAIL.
(They can not go unpaid.)

Volumes 16, 17, 18, 19, or 20, *unbound*.....$1.12 each.
Volumes 16, 17, 18, 19, or 20, *bound*.....$2.00 each.

BINDING.—Sets of numbers brought to the office will be bound up neatly (in our regular style of binding the *Agriculturist*) for 50 cents a volume.

PREPARED COVERS.—Covers for binding, neatly made, with title, etc., gilt upon the back, ready for the insertion of the sheets by any bookbinder, can be furnished for Vols. 13, to 20 inclusive, at 25 cents per cover. *Covers can not go by mail.*

EXTRA PREMIUMS,

For June and July, 1862.

STRAWBERRY PLANTS

Sent Free by Mail.

The Strawberry premiums offered previous to May 10th seemed to give general satisfaction. We sent out many thousands of plants to almost every part of the country, all of which, we trust, are growing finely. (The plants were growing too rapidly to be forwarded by mail *after* the advertised time, May 10, and a few sent after that date, to late applicants, perhaps did not reach them in so good order as if sent earlier.) In response to many requests, we continue the Strawberry Premiums, the plants to be sent out the latter part of August or the first of September, according to the season, and the locality for which they are designed. We are propagating plants in our grounds, and have engaged a supply from elsewhere. At present, we will only propose the **Triomphe de Gand,** and **Bartlett,** as hitherto offered; but should the present season develop superior qualities in other new varieties, an equivalent of the new selections will be given. A list of such sorts (perhaps several) as we can furnish will be published in the *August Agriculturist*. Plants to set out, in quantity, early in September, will multiply somewhat this year, and bear next Spring.

CONDITIONS:

PREMIUM I. To any person forwarding, (*now* or before August 1st), ONE subscriber to the *American Agriculturist*, at $1 a-year, we will present (if desired) **Ten Plants** of the **Triomphe de Gand Strawberry,** or an equivalent selection from other sorts that we may have, to be forwarded in August or September, according to their destination, as above stated.

PREMIUM II. For TWO subscribers, the same as Premium I, but **Twenty-five Plants**, or their equivalent, in other new choice varieties, instead of ten.

PREMIUM III. For THREE OR MORE subscribers, the same as Premium I, but **Fifteen Plants** or their equivalent in other varieties, for **each name.**

Premiums for Northern Grown Cotton.

One Hundred Dollars are offered for the best five specimens of cotton grown above latitudes 38° and 40°, this year. See particulars in February *Agriculturist*, page 64.

American Agriculturist in German.

The AMERICAN AGRICULTURIST is published in both the English and German Languages. Both Editions are of the same size, and contain, as nearly as possible, the same Articles and Illustrations. The German Edition is furnished at the same rates as the English, singly or in clubs. A club may be part English, and part German.

American Agriculturist.

For the Farm, Garden, and Household.

A THOROUGH-GOING, RELIABLE, and PRACTICAL Journal, devoted to the different departments of SOIL CULTURE—such as growing FIELD CROPS; ORCHARD and GARDEN FRUITS; GARDEN VEGETABLES and FLOWERS; TREES, PLANTS, and FLOWERS for the LAWN or YARD; care of DOMESTIC ANIMALS, &c., &c., and to HOUSEHOLD LABORS. It has also an interesting and instructive department for CHILDREN and YOUTH.

A full CALENDAR OF OPERATIONS every month.

THREE to FOUR HUNDRED, or more, illustrative ENGRAVINGS appear in each volume.

Over TWELVE HUNDRED PLAIN, PRACTICAL, instructive articles and useful items, are given every year.

The Editors and Contributors are all PRACTICAL WORKING MEN.

The teachings of the AGRICULTURIST *are confined to no State or Territory, but are adapted to the wants of all sections of the country—it is, as its name indicates, for the whole* AMERICAN CONTINENT.

TERMS—INVARIABLY IN ADVANCE.
(For either the English or German Edition.)

One copy, one year.....	$1 00
Six copies, one year.....	5 00
Ten or more copies one year.....	80 cents each,

☞ Add to the above rates: Postage to Canada, 6 cents, to England and France, 24 cents; to Germany, 36 cents

Postage anywhere in the United States and Territories must be paid by the subscriber, and is *only six cents a year*, it paid in advance at the office where received.

All business and other communications should be ad dressed to the Editor and Proprietor,

ORANGE JUDD, 41 Park-Row, NewYork City.

VOLUME XXI—No. 7. NEW-YORK, JULY, 1862. NEW SERIES—No. 186.

Entered according to act of Congress in the year 1862, by ORANGE JUDD, in the Clerk's Office of the District Court of the United States for the Southern District of New-York. ☞ Other Journals are invited to copy desirable articles freely, if each article be credited to *American Agriculturist.*

July.

"Ye swains, invoke the powers who rule the sky,
For a moist Summer and a Winter dry:
For Winter drought rewards the peasant's pain,
And broods indulgent on the buried grain.
Hence Mysia boasts her harvests, and the tops
Of Gargarus admire their happy crops.
Then when the suns too fiercely play,
And shriveled herbs on withering stems decay,
The wary plowman, on the mountain's brow,
Undams his watery stores; huge torrents flow,
And rattling down the rocks, large moisture yield,
Tempering the thirsty fever of the field."—VIRGIL.

We are again amid the fervid heats of July, the hottest and oftentimes the dryest month of the year. One now only needs to look over the parched fields, especially in a dry season, to understand the need of irrigation. Even in seasons of average moisture we could use to advantage many times the quantity of water that falls from the clouds. It would always make the hay crop a certainty, and often quadruple the yield of grass in the irrigated fields. It was not strange that the Romans living under the bright skies of Italy, early found the advantage of damming their mountain streams, and turning them at pleasure upon the meadows below. It would seem from the account of Virgil, that whole districts were famous for the crops procured mainly by this method. Irrigation must have been an art well understood long before the Christian era. Is it not strange that in a climate quite as much subject to drouth as that of Italy, irrigation should be almost unknown among us? With a climate that demands it, and with unrivaled facilities for its practice, in most of the northern States, not one farmer in a thousand has availed himself of the treasures of water within his reach. Nothing could better show the neglect of agriculture among us as an art than this fact. Few people are more ingenious than ours, or more quick to take advantage of the facilities which Nature offers to save labor and to create wealth. We abound in all useful inventions and labor-saving machines. We dam streams to turn innumerable wheels for manufacturing purposes; to make fish ponds, and adorn our ornamental grounds; to make model lakes and raise our annual crop of ice, for the delight of Europe and the Indies. But how rarely is a stream turned from its course to fertilize the land and increase our harvests.

Few have any conception of the value of water as a fertilizer. Many turn the streams made by rains in the highways into the adjacent fields, but they attribute all the increased luxuriance of the grass to the matter deposited. No doubt street refuse, such as the rain washes into the meadow, is an excellent fertilizer, but the rain itself contributes to the result. Far beyond the line of deposit, you see the effects of the water.

Just how the water operates to fertilize the soil we may not be able to state. Of the fact there can be no doubt. We see the power of water to make crops in every drouth that comes. There are fields of light gravelly soil, whose crops of grass are nearly doubled in wet seasons. It is pretty safe to infer that water makes the difference. Water is a powerful solvent, and helps the decomposition, not only of vegetable fiber in the soil, but of its mineral constituents. You can not wash a stone so clean that water will not act upon its surface, and after a few hours wash away something more from it. It is probable that the water is all the while preparing plant food from the soil where it is present, and of course the more of it we pass through the soil, the more nourishment the roots of plants are enabled to take up.

We have recently examined two small valleys, flowed for skating during the winter, and drawn off in early Spring. In both you can detect the water line in winter by the greater luxuriance of the grass. Both streams that fed these ponds are dry, or nearly so, in summer, and never carry any very large volume of water. The basins that contain the water are small, and mostly covered with grass, so that they are rarely turbid even in rains. There is little appearance of sediment when the water is drawn off in the spring, and it is nearly certain that the beneficial effect is mainly owing to the presence of water in the winter season. If the water helps the grass crop under these unfavorable circumstances, it must help it much more when it bears a rich deposit, and is applied at the growing season.

We have in this State two examples at least, of the successful application of irrigation to farms—that of A. B. Dickinson, of Steuben Co., and L. D. Clift, of Putnam County; accounts of which were published in the Agricultural Transactions for 1855. In both these cases, the method is simple and the expense not beyond the means of most thriving farmers who have streams convenient for this purpose. In both, the results are all that could have been anticipated. The method is to dam the stream at a point above the lands to be watered, and to turn it on at pleasure, by means of a gate and channels of distribution. These main channels are furnished with side conduits which are merely furrows made with the plow and having just descent enough to carry the water. When the water is turned on these channels overflow, and the water is distributed over many acres.

Mr. Clift pursues his irrigation even in Winter, and it is this feature probably that will be looked upon with more hesitation than any others. The water freezes sometimes as it flows, making a broad field of ice a foot or more in thickness, where it remains until dissolved by the suns of Spring. It is probable that the ice affects the soil thus protected just as the ice-covered pond does. It is completely shielded from the alternate thawing and freezing; the frost does not strike in deeply, and comes out very early in the Spring. It is his testimony that "the grass in all such places is first in Spring, and grows with great rapidity." He also improves other seasons when the stream is charged with sediment, and spreads it over the land as a top dressing. Besides the sediment which is carried in the water, a good deal collects in the bottom of the pond, which is carted out when the water is drawn off, and makes excellent manure. This is spread upon portions of the field that receive the smallest supply of water. He cuts about a hundred tuns of hay on forty acres of land, which is certainly double the average for the mowing land of the state, and uses no other manure.

Mr. Dickinson makes great account of increasing the natural deposit of sediment by artificial means. He plows and harrows land that is to be overflowed, and stirs up the soil after it is under water to make it very muddy. Even the subsoil that is thus spread over grass land is found to be an excellent fertilizer. His grass crops are enormous, and the best possible commentary upon his method of irrigation.

Now we have thousands of farms all over the country quite as well, or even better situated for artificial watering than these. In many cases a few days' labor by the ordinary working force of the farm would make a pond and the necessary channels for watering a few acres. The work once begun would demonstrate its economy and lead to the watering of all the available portions of the farm. Lands that are now an encumbrance, hardly paying taxes, might be brought into a high state of productiveness. We call the attention of our readers to this very important topic at this season, when the scythe sweeps so many acres prolific in five-finger and briars, but poor in grass. Cheap and careless irrigation pays, and the more systematic and perfect it is, the better it pays, as a general rule. Use our streams rightly, and we shall find them richer than Pactolus, plowing over golden sands.

Calendar of Operations for July, 1862.

[A glance over notes like the following will generally call to mind some piece of work that would otherwise be forgotten or neglected. The remarks are more especially adapted to places between 38° to 45°; but will be equally applicable farther North and South, by allowing for latitude.]

Farm.

Clear the deck for action. The great fight of the year is now close at hand—with many of our readers already begun. When the grass is fit to cut, haying must take the precedence of every thing else. The few days of cultivation that remain should be improved to the utmost. Keep the horse hoe and cultivator moving until the corn is too large to allow the horse to pass. Hoeing even to the time of silking pays. The stirring of the soil not only destroys weeds but admits air and moisture freely to the roots of plants. Cloudy days can sometimes be improved in hoeing, even to the last of this month.

It is miserable economy to undertake haying with a short supply of help. There is less need of it now that we have the help of the horse in mowing and reaping. The mowers and reapers have reached almost every neighborhood, and the small farmer who does not wish to buy a machine, can hire his work done with one. This saves the muscles and money at the same time. It puts the hay into the barn just at the time when it is worth the most for fodder. A single day of overwork, under a burning sun, sometimes lays a man up for a month. Hired labor will pay in the hay harvest, if at any time.

Barns and Sheds should be put in order immediately, if not ready to receive the new mown hay. There should be barn room enough for all the hay made upon the farm. As grain is now so generally thrashed soon after harvest, it is of less importance to put it under cover. If stacks must be built, make them very large, and remove them to the barn in the Winter for feeding out. We hope to see the practice of foddering at the stack-yard banished from the northern farm. It is hard on the cattle, and still harder on the farmer's purse.

Buckwheat—Sow a large breadth of this if there is likely to be any deficiency in the other grains. Read article on page 205.

Butter—Nothing requires nicer handling than this article. Perfect cleanliness in the utensils and thorough working, so that all the buttermilk is expelled, will add several cents a pound to the market value. A cool spring in the milk room is of great value in this business. Every dairy farmer ought to have an ice-house. With this he can always manage the temperature of the milk and bring his butter to market in the best condition. Sour milk and whey should be kept at a safe distance from the milk.

Cabbage should be more largely cultivated upon the farm. It is a good succession crop to early potatoes, and does well oftentimes, where from any cause the first crop fails. They may be planted at once in the hills where they are to grow, or transplanted from the seed bed a little later. It is of great value as a succulent fodder for cows, and will last well stored until Spring. It is excellent for pigs and poultry.

Cheese can be made where the facilities for making butter are not first-rate, or on farms too remote to admit of weekly marketing.

Draining is an item of business always on hand, when other things are not pressing. Drains are best laid in dry weather, and if we could have our choice of seasons we would always take Summer and Fall. Improve any leisure between hay and oat harvest to make drains. The proofs of the profitableness of this business are so clear when we have once begun, that it is rarely abandoned, until the farm is sufficiently drained.

Fences will need little attention, if they were thoroughly repaired in the Spring. The inclosed grain and clover fields will need looking after to guard them against cattle.

Grass and Clover Seed—Now is the time to secure clean seed of the best quality. You know what you raise. It is not always so clear what you buy, until it is too late. Select the cleanest piece of grass, clean out all the weeds, and you will have only what you want to grow.

Haying will commence in this latitude early in July. Begin with the clover and cut as the different fields are passing out of bloom. The indication of cutting time is, with many, when half the heads are turned brown. Clover makes the best hay in the cock, with only partial sun drying. Other grass is generally dried too much. With the hay caps, we may take our time in hay-making, and cure more in the cock, than we used to. Banish the whiskey jug and allow ample noonings. If stacks must be made, lay rails or other lumber to keep the hay from the ground.

Hay Mows—Ventilate by means of ducts, made by using grain bags filled with hay, set in the middle of the mow at the bottom, and gradually drawn up as the mow increases in hight, the hay being packed tight around them.

Hedge rows and bushes in pastures may be subdued by repeated cuttings in hot weather. The bush scythe is used to best advantage at this season.

Hoeing—Let no weeds grow among the corn, and substitute the horse for the man, as much as is possible, in destroying weeds. Keep the hoe and cultivator very near the surface, lest the corn roots receive damage.

Ladders for the hay mows and lofts, and stacks, should be provided, if not already on hand. They can be made on rainy days. Ladders and hay rigging for the cart, should be put in order. We do not want to repair a broken slat, or supply a missing stake, when a shower threatens, and a load of hay must come in within an hour or be drenched.

Manures—All kinds of vegetable matter, weeds and grass from the swamp and roadside, leaves from the woods, small brush and clods, sea weed and mud, make valuable manure. Gather every thing of the kind that is available, and put it in the compost heap. Either cut before the seeds ripen, or secure thorough fermentation, that there may be no foul seeds in the manure. Sinkspouts and privies will need looking after. There is waste wherever there is the smell of ammonia. Subdue it with plaster, muck, loam, or some other good absorbent.

Mowings—As soon as the grass is cut, spread fine, well rotted manure uniformly upon the surface. It is the best time to manure grass land. If it rains soon, the effect is very great, and at any rate, just as good as if applied at any other time.

Oats—Cut at early maturity, as directed for wheat and rye. Store where there is good ventilation and thrash early. The fall market is sometimes best for oats. At any rate, it saves the depredations of rats, which can not be prevented in the stack and mow.

Pastures—The great trouble is overstocking. They have no change, and no chance to recuperate. Corn, sorghum, rye, and other green crops fed out now, will save the pastures, and in the end secure more feed.

Poultry—Keep them from the grain fields until after harvest, then allow them to glean.

Potatoes—The ground should not be disturbed after blossoming until digging. Dig early varieties as they mature and sow turnips or set cabbages. There is ample time for a good crop of either if manure be used. There is often a difference of fifty per cent in the price of potatoes this month and the next—hence market early.

Rye—Cut before fully ripe, when the grain is passing out of the milky state.

Seed rye, Wheat, etc.—Save the best parts for seed, and leave until fully ripe. Remove all weeds and thrash with flails soon after harvesting.

Sheep—Give good pasture or sell a part of the flock. The profit is in well fed sheep. They can be made efficient helpers in subduing brush pastures. Goats are still better. Visit and salt weekly, and see that they have good water. Watch against the appearance of foot rot.

Soiling Crops—Sow millet and corn to be used for soiling late in the season. If not wanted green, it makes valuable dry fodder. Guard against a scant supply of food Summer and Winter.

Swine will find good picking in the grain fields after the crop is removed. Fleds and fat are made much more economically in warm, than in cold weather. Feed those confined in the pen with corn stalks, and other green fodder. Give water as well as meal. They want plenty of succulent food until frost comes.

Timber cut during this and the following months is considered more durable than that felled in Winter, particularly those kinds that abound in sap. Anticipate the wants of next season by cutting now.

Tanner's Bark—Hemlock and oak bark will "run" during most of July. Peel whenever leisure offers, if you have trees that need cutting. Shelter the bark as soon as it is sufficiently dry.

Tools—Examine before you begin to use them, and see that every nut and bolt is tight. Oil bearings and sharpen knives and cutting tools. Protect all tools from the weather. Improve rainy weather in repairs, painting, etc.

Turnips—Sow largely all vacant places where other crops are removed, and between the rows of corn. Transplant rock and French turnips. There is still time for a good crop. A spoonful of bone dust or superphosphate to each plant will make a crop on almost any tillable land. Cattle are very fond of all kinds of turnips, and thrive on them—the best proof of their value.

Weeds—The pest of the farmer, and the curse of slovenly tillage. Make war on them early and late. Give no quarter. Canada thistles, snapdragon, briars, high and low, live forever, wild mustard, dock and burdock, white weed and Johns-wort, wild carrot and daisies, their name is legion. Do not let one of them go to seed. Buckwheat is a good cleansing crop on foul land. Till thoroughly among all hoed crops. Cut grass early before the seeds of weeds ripen. Sprinkle salt on Canada thistles after the stalks are cut, so the cattle may crop them close.

Wheat—Cut as directed for rye. Keep the grain clean if intended for seed. It is a moral offence, dishonesty, to sell foul seed with the wheat. It justly affects the market price, even more than the cost of its removal.

Orchard and Nursery.

There is not much to be done in the orchard this month, if former directions given in the *Agriculturist* from time to time, have been followed. Early in July is a good time to prune both in the orchard and nursery. The rapid growth of new wood will soon heal over small wounds, and the wood will season firm and hard where large limbs are removed. Neglected orchards should by all means receive a good but judicious trimming now, and young trees will be improved in appearance and rendered more fruitful by heading back the new, luxuriant branches. Do not allow suckers about the trunks or on the limbs, to rob the trees of their needed food, and see that only the cions are allowed to grow in those branches which were grafted in the Spring. After trees have attained considerable size, it is better to keep the orchard under tillage, plowing lightly and harrowing frequently during the Summer, but do not depend upon a crop of anything but apples. The orchard is not often sufficiently manured to yield a crop of fruit, make a good wood growth for future bearing and give a crop of grain, corn, potatoes, or even grass beside. By no means allow a strong turf of grass to grow about the roots of young or newly planted trees; the grass will appropriate moisture and food needed by the trees.

Cherries are now ripe, and the crop is abundant in most parts of the country, too much so to warrant sending a long distance to market. Dry and bottle freely for Winter and Spring use. Save pits for nursery planting, mixing with earth in open boxes, and set them in an outbuilding or expose to the weather.

Thin the fruit of young trees, especially on the newly planted dwarfs. It is better to remove the whole from trees set last Spring, as the tax upon the vital powers of the tree caused by transplanting is quite sufficient without the extra effort required to perfect fruit.

The nurseryman will begin to bud plum, cherry and pear trees by the middle of the month. Use every precaution in securing true sorts, and mark the rows carefully. Insert the buds close to the ground. It is not necessary to remove the wood from the bud, except in budding on dwarf stocks. Stocks budded last season, may now be rounded off close to the growing bud. See that all suckers are removed. Read article on page 200.

Inarching may now be performed on both deciduous and evergreen trees. Layering is also in season, on old and new wood. With grape vines and other climbing or running plants use the new growth, while quinces and shrubby plants in general do better with wood of the previous season's growth.

Insects are now troublesome, unless they were kept in check as advised last month. Continue to dust plum trees with lime, or syringe with soap and water, or the mixture recommended on page 177 last month, to repel the curculio. Make friends of the birds, even if they do take a few cherries. This is the best season in which to destroy scale. The old shells have fallen off and the small dust-like specks, which are the recently hatched eggs, are readily removed by strong soap suds, or potash and water—one pound of potash to a gallon of water, applying with a scrubbing brush.

Plow or run the horse-hoe between the nursery rows, and use the hand-hoe to keep down weeds.

Kitchen and Fruit Garden.

It is a luxury to see things grow now. The change is visible from day to day. The peas are in their glory, the beans blossoming, the tomatoes full of green fruit, and the corn beginning to tassel. Follow up every department of the garden with the hoe and the watering pot. Make the most of the sink spout and other sources of liquid manure. Water newly set trees, and dwarf pears and grapes, keeping the mulch moist. Nothing will swell the fruit like liquid manure. Keep down the weeds and leave no spot vacant. We may as well have two or three crops as one.

Asparagus—The cutting season is over, and the plants should be stimulated, to repair the damage of the repeated cropping. Clear of weeds and give a good dressing of stable manure or compost, an inch or two thick.

Beans—Gather for use as they fill. Early beans may still be planted for a late crop of string beans, or for seed. They make an excellent pickle.

Beets may still be planted for Winter use. Hoe frequently, and thin to eight or ten inches in the row. They bear transplanting as well as a cabbage. Any surplus will be good for the cow and pigs, if not for greens.

Blackberries—Tie the new shoots to the trellis or stakes. Shorten in the main stem and branches to help the forming of fruit buds, and pull up small canes unless you wish to multiply them. Branches heavily laden with fruit should be carefully and securely tied up.

Cabbage and Cauliflower—Still sow and transplant for late crops. There is always a large home market for these and for turnips. If the stumps are left where the heads are cut for table use, a large amount of succulent food will grow for fall feeding.

Celery—Transplant until the last of the month for late crop. Hoe and water often. The more water the better, if there is good drainage. The excellence of this vegetable depends upon rapid growth. (See page 213.)

Corn—Still plant sweet corn for late use, and for drying. What is not wanted for the table, will find a ready market in the pig and cow yards.

Cucumbers may be planted for pickling. Guard against insects, and hoe and water until the vines cover the ground. Pickled cucumbers with good cider vinegar are wholesome, used in proper quantities.

Currants—Gather as they ripen and eat freely every day, from the bush and for dessert. They are one of the best safeguards against fevers and summer complaints. They should be ripe for jellies, and fully matured for wines and preserves. The bushes may be pruned, cutting out old wood as soon as the fruit is gathered. The juice preserved and bottled, makes the basis of a refreshing beverage. This fruit is so easily grown and is so healthful that every farmer should have a full supply. Watch against the currant aphis, scale, and the borer.

Egg Plants—Keep well hoed, and forward by stimulating manure, lest the frost cut them off.

Endives—Sow first of the month. (See article on p. 213.)

Espaliers, or trees trained to trellises or against walls are ornamental and more productive. They need to be pinched in, and where that has been neglected, superfluous wood should be cut out. Thin the fruit where much has set. Size and quality will both be improved.

Gooseberries are by far too rare in the farmer's garden. The first pickings make good sauce and pies. The later are fair eating from the bushes and at dessert. Keep mulch around them to prevent mildew.

Grapes—Continue to thin out and pinch back the shoots. Thin the bunches to one or two on a shoot. One gives the best fruit. A crop is frequently spoiled by the inexperienced, by leaving too much fruit to ripen. Also thin the bunches, removing small and imperfect berries. Keep the border free from weeds and all other crops. Grapes are enough for one piece of ground. Mulching and liquid manure are beneficial, until the fruit begins to turn. In Summer pruning, the new shoot that is to bear the fruit should be left to grow, until it is two or three leaves beyond the last bunch. From two to four bunches will set on a shoot if the vines are vigorous. Nip off the shoot at the third leaf beyond the last bunch, as soon as the berries are of the size of small peas. If the vines are young, not more than one bunch should be left to mature. In old vines two may be left, the lowest bunches. The uppermost bud in the axil of the last leaf will soon start. This should be left to grow a while, and then be pinched off, leaving but a single leaf. The bud by this leaf will start after a little while, and the pinching process is to be repeated. At the base of every leaf-stalk such shoots (called "laterals"—by the Germans, "thieves") may start, and if allowed to grow, will destroy the main bud, which forms at the base of each leaf. Treat them as directed for the leading bud. Pinching in the laterals ensures well matured buds for the next year's fruit, and though the process involves considerable labor, it secures the most perfect grapes.

Herbs—The best are dried in the shade, and preserved in boxes that will hold their aroma. Cut while in bloom.

Hoeing is a substitute for manure and water, and is always in order, until the plants cover the ground.

Insects require the constant attention of the gardener. They are alike destructive to fruits and vegetables, and should be trapped by all possible methods. Study their habits and experiment to destroy them. Encourage the presence of birds, toads and chickens. After this month chickens will do little harm in the garden, and will live mainly upon insects.

Lettuce is very refreshing at this season, and should be much more generally used than it is. Grow the kinds that head well, and still plant for a succession.

Manure all backward plants by top-dressings and manures in solution. You can drive a plant as easily as a pig, if you only know how. With plenty of manure, there is no need of a lagging garden. A shovelful of poultry droppings dissolved in eight gallons of water will make a good persuasive to all reluctant plants.

Melons—Cultivate as cucumbers. Put a board or flat stone under them as they grow large.

Mushrooms—Prepare the materials for late beds, according to former directions. See article on page 213.

Onions—Weed and cultivate without drawing the dirt around the bulbs. If the maggot trouble the plants, try a weak solution of oil soap, say a pound to eight gallons of water. Apply with a watering pot. Thin the plants, if you desire very large onions. Seed may still be sown to provide very small bulbs for planting next Spring.

Peas—Sow for late use, if your vines do not mildew late in the season, and if you desire peas amid the profusion of Autumn fruits and vegetables. We have never found late peas very much appreciated. Save the best pods for seed, and pick as soon as dry. Clean up the pea ground as soon as the vines grow yellow, for turnips or other late crops.

Potatoes will have nearly got their growth this month. Plant cabbage or turnips between the rows at once, or clean the ground when all are dug, for spinach and other late crops.

Preserving fruits and vegetables. Read articles in last and other numbers, and lay in a full supply. Fruits can now be made a cheap luxury the year round. They are much cheaper than pills.

Raspberries—Cut down old canes as soon as the fruit is gone, and thin out the new ones, unless you want to multiply them. Three or four canes to a stool is enough. Keep the ground around them well hoed, but do not disturb the roots.

Rhubarb has had its season, and now that fruits are getting plenty it may be left to recuperate if it has been hard plucked. If fruit should be scarce, it may be preserved in the same manner, or dried in the same way as apples. The late growth also makes a good wine, if that name is proper for any thing but the juice of the grape.

Seeds—Pay strict attention to sowing the seeds of cabbage, turnips, and all plants that mature early. After the pods begin to turn yellow, they will ripen more securely in the house, or under some shelter.

Strawberries—After bearing is over, weed the beds, and cut the runners that are not wanted for new plants. Prepare new beds, making them deep and rich, where you want them to last for several years. Most varieties do best in hills in the garden. With liquid manure they will do well on quite poor soil.

Thinning is generally very much needed among carrots and all the root crops—among melons and fruits. One good fruit or vegetable is worth many poor ones.

Tomatoes—Some recommend training to trellises and on brush. They ripen quicker on the ground, and for this reason we let them follow their bent. Pinch off the ends of the branches, and keep them within bounds. They will make better fruit.

Transplant to fill vacancies every where. A good deal may be done to remedy poor seed, or the ravages of insects this month. This can be done in the hottest weather with a little skill.

Weeds are not useful or ornamental. Keep the hoe and cultivator moving, and the garden clean as a parlor.

Flower Garden and Lawn.

As too frequently cultivated there is a dearth of flowers in July. Many of the early bedding and other plants, including the bulbs, lilies, peonies, dicentra, roses, etc., are nearly out of flower, and it is too early for the annuals, and for dahlias, gladioluses and other Autumn bloomers. The chief reliance must now be upon the verbenas, petunias, fuchsias, heliotropes, pinks, geraniums, hollyhocks, tall phlox, salvias, some of the remontant roses, etc. By drawing freely upon the potted plants of the green-house, the list may, of course, be much extended, but a good assortment of the above will make a fine show until relieved by later flowers.

A few of the quick growing annuals will flower late in the season if sown early this month. The perennials may properly be sown now for blooming another year.

Bulbs which are to be reset this season should be taken up and dried at once. Label them and wrap in papers or pack in dry sand until Fall, when they are to be planted.

Climbing plants will need regulating to keep them within due bounds. Do not allow those which are to be laid down for Winter, to become too much entwined about the trellis, or run through the lattice. Train them carefully upon one side.

Dahlias, gladioluses, etc., should be well staked and tied to prevent breaking down by high winds. Cut off a portion of the side shoots of the dahlia. One stalk is better than several. Look for and destroy borers, which often penetrate the stalk at this season.

Evergreen and other hedges should be clipped early this month, if it was not done in June. Single evergreen trees may also be pruned to advantage, especially if they are to be kept in a bush or shrub form. By no means destroy their beauty by trimming to a naked stem. They should always branch close to the ground.

Roses will still require some care to keep off that troublesome pest, the slug, which eats the leaves until they look like skeletons. A few good sprinklings and syringings with 1 lb oil soap mixed in 6 gallons water will effectually rid the bushes from these pests. The rose bugs will not fancy the application. Remove the flower stems as soon as the bloom has fallen. By cutting back freely a late bloom is often secured.

Lawns and Grass Edgings—Mow or shear once a fortnight, to keep a thick, green bottom. If the short grass is left evenly spread upon the surface, it serves to protect the roots from the sun, is soon hidden by the new growth, and its decay eventually enriches the soil. Do not let the turf encroach upon the flower borders, or grow too closely around newly planted, or even established trees. If suffering from dryness, a hydropult, or other sprinkler, may be used to advantage, sprinkling with the waste wash water, or with liquid manure, well diluted with water if it is dark colored and strong.

Verbenas should be pegged down as they extend their growth, until they form a perfect mat.

Water must be given occasionally to trees and shrubs set in the Spring, also to herbaceous plants. Frequent stirring of the ground will do much toward bringing up moisture from the soil, and it assists in absorbing dews. As often applied, water does little good; a pail of water dashed upon the ground soaks in very little, while it helps to bake the soil. Scoop out a hollow about the tree or plant, pour in the water, and when soaked in, return the surface soil.

Weeds are very apt to run up and go to seed under the cover of plants of similar foliage; of course they will not be tolerated by good gardeners.

Green and Hot-Houses.

These houses are nearly empty now, and require very little attention. Those containing tropical and other plants which can be better controlled than if set in the open ground, should be well cared for, one of the first requisites being frequent sprinklings and syringings with water. Evaporation is very rapid during the heat of Summer, and water should be given at least three times a week, not a mere sprinkling either, but a thorough soaking, which will do no harm, provided the drainage is good. Propagators prefer a glass structure in which to strike cuttings for increasing their stock. They can better regulate light and shade, heat, moisture, etc., and usually devote one house to this purpose, even in Summer. It is now time to put in cuttings of most plants intended for Winter flowering. The old and overgrown specimens should give place to new and vigorous plants which the skill of the florist easily produces from the parent stock.

Grapery and Orchard-House.

From the present time to the full ripening of grapes peaches, nectarines, etc., care is necessary to check unnecessary or wild growth, to secure a perfect ripening of the wood which it is intended to preserve, to prevent mildew and ripen the fruit. There must be a good supply of foliage beyond the fruit, and in good light. The fruit need not be in the sunshine, but is better if shaded by its own leaves. This is particularly true of grapes, the skins of which are thickened by the action of the light. Thin out the branches even among the smaller berries. Look out for and remove shriveled, spotted or mildewed berries, tie up shoulders of clusters by strings to the wires or rafters. Use sulphur flowers freely upon the fruit and foliage. Withhold superfluous water during the formation of the stones in stone fruits and the seeds in grapes gradually increasing the supply again after they have become firm. Summer pruning, pinching, etc., must always be done with reference to that part of the current year's growth which is to be permanent, and with reference to the production of fruit buds for the next year's crop.

Apiary in July.

Prepared by M. Quinby—by request.

In this month, the bees usually obtain their best stores. If the colony is strong, their combs are soon filled to overflowing. A large portion at this time, should contain brood, but when honey is abundant, and store room limited, the comb which may contain brood, is apt to be much reduced, so much so that, in some instances, when cold weather comes on, the colony is quite too small. The Italians, particularly, are apt to fill up with honey instead of brood; but as they are longer-lived than the black bees, the effect is not so disastrous. A hive stored to its utmost capacity is not in as good condition for Winter as one that has a portion of its cells empty. The use of surplus boxes, then, is not only an advantage in secur-

ing honey, but a benefit to the bees. During the yield of honey, the full boxes should be changed for empty ones as fast as filled. In getting the bees from the boxes, much honey is often lost by the ordinary methods recommended. As long as flowers yield honey plentifully, it will do to set the full boxes down by the hive, in the shade of some tree or out-building, or in a darkened room with a small crevice to let out the bees. But as soon as it is scarce, the boxes so left are sure to be robbed. One man put nearly his whole crop in the barn, shut the doors, and went off to his work. On his return at noon, he found his boxes empty. The utmost care and some skill are required on some occasions—especially with Italians—to get rid of the bees, and save the honey. The directions hereafore given in the *Agriculturist* are probably as effectual as any simple arrangement. Take an empty bee-hive, put in the boxes on their sides, combs vertical, in such a way that the bees may creep out of all. Throw over them a sheet, that no bees may get in or out. After standing a little time, the bees, in their endeavor to escape, will get on the under side of the sheet, when it may be turned over; by repeating this a few times all may be disposed of. Bees in this way will not sting, unless provoked at first. To save the honey through the hot weather, put it in a dry place, and cool, if possible, to prevent the moth eggs from hatching. Paper or cloth may be pasted over the bottom to keep out moth and other insects.

Boxes should stand the same side up as they did on the hives. Swarming seldom continues later than the middle of this month. It is unnecessary to watch a hive for swarms later than eighteen days after the first one issued from it, although bees enough may be counted out for two. When done swarming, notwithstanding all care to supply queens to old stocks as they are lost, there will be some queenless ones yet to be supplied. Ascertain as early as possible which they are. With the movable combs it may be known in a week or two by examining combs for eggs or brood in the cells; but with the box hive, it may be three or four weeks before it can be ascertained. There must be sealed broods before it can be seen, and by this time, when they happen to be destitute, the colony is often reduced too much to swarm, if they have to rear a queen. A few very small late swarms should be hived to have queens on hand to supply these with a laying queen at once. There is a gain of three weeks' time in breeding, over raising one from brood, and the difference, perhaps, of saving or losing the colony. One who has taken no pains to ascertain how quickly a swarm of bees die off that have no queen, can not realize the importance of her presence with a supply of eggs.

When combs have become eight or ten years old it is well to prune out, and let the bees construct new. To avoid waiting brood unnecessarily, which is so important as honey for the prosperity of the hive, it should be done three weeks after the first swarm. Take just time enough to get through before dark. Drive out the bees as directed for transferring combs, and set them on the stand until their own is returned. Take out all the black combs in the center of the hive that have been used for breeding, leaving those at the top and sides where they are seldom used for brood; they are usually filled with honey, and are a good start for refilling the hive. A moderate sized colony will always fill up without this help. Invert the hive containing the bees and set the other over. The bees will take up all the dripping honey, and be in the upper hive by morning, when they may be set on the old stand. Three weeks after the first swarm is also the best time to examine for diseased brood. If found, pruning is not sufficient; the colony must have a *clean, empty* hive. If foul brood is discovered *at any* season, when honey is to be had, the bees should be put into an empty hive; if they get enough for Winter, it is well, if not, feed them, or, take out the bees in the Fall, and save the contents as a beginning for some swarm another year.

There are more moths about the hives this month than in any preceding month of the year; and there are more chances of their finding places for depositing their eggs. Very small swarms, old stocks that have swarmed freely, and but few bees left to protect the combs; and above all, queenless stocks, afford great inducements to the moth to deposit her eggs. Although a few worms may not destroy the colony, they will injure a weak one much more than a strong one. The number that destroys one, might hardly injure the other. Ascertain which are weak and by frequent examinations, assist in destroying the worms. Strong colonies will do without much help. Put old pieces of comb under the hives that are part fall; take out once in two or three days, and kill the worms that have gathered in them. Set shallow dishes containing sweetened water near the hives at night; hundreds will get drowned.

Wild Bees.—A correspondent inquires, "How wild bees in a hollow log may be transferred to other hives?" In the same way as bees are transferred from one hive to another, namely, by drumming them into a box or hive set above them upon the log, inverted, if possible, as one hive would be set upon the top of another inverted hive. The comb, after the bees are out of it, may be cut out, and fastened into frames, or inserted in the hive, in which the bees are to be put. Follow directions as given by Mr. Quinby in Apiary for previous months.

Exhibition Tables at the Office of the American Agriculturist.—

The following articles have been presented since last report:

FRUITS, ETC.—Lancaster Greening Apples, from W. Miller, jr., Carlisle, Pa.....Lychee fruit, (Nephelium litchie) from China, from D. C. Eaton, N. Y.....Apples for name—Campbell," from J. G. Holbrook, Chappaqua, N. Y.... *Strawberries.*—From Mr. Pell, Infant Orphan Asylum, N. Y.....Hooker's Wilson's and Triomphe de Gand, in pots, from C. S. Pell, N. Y., Orphan Asylum.....Wilson's and Austin Seedlings, in moss only, from J. C. Thompson, Staten Island....Longworth's Prolific—fine—from Mrs. Alston, Brooklyn, N. Y.....Triomphe de Gand and Wilson's, from J. C. Thompson, Staten Island.

FLOWERS, ETC.—Rodanthe Manglesii, Arocclineum Roseum, etc., in bloom, from O. Judd, Flushing....Cut flowers, from A. Cummings, N. Y....Ditto, from Mr. Westcott, N. Y.....Ditto from A. S. Fuller, Brooklyn Nurseries.....Ditto from J. C. Thompson, Staten Island.....Salvias in variety, Veronica Speciosa, Pentstemon ovatus, Lupinus polyphyllus, Dictamnus fraxinella, Spiræa, Iris, etc., Geraniums, Petunias, Petalonia, etc., from O. Judd, Flushing, L. I. ...Branch of Wistaria, from Mrs. Hall, Williamsburg, L. I.

VEGETABLES, SEEDS, ETC.—Desiccated vegetables—Cabbages, Onions, Potatoes and Carrots—from the N. Y. Desiccating Co., by Mr. Estus Woodbury, N. Y.....Cucumbers grown on 12 rods of ground, from Jas. Wilkinson, Minneola, Kansas....Corn from three ears—weigh 23 ounces—from J. C. Cooke, Newport, Vermilion Co., Ind. ...Contraband Sweet corn—black, very curious, and said to be very early—from J. Conklin, Dobbs Ferry, N. Y.....Early Short Prolific Cucumber, April 1, and gathered June 9)—fine—from G. M. Usher, Port Richmond, L. I. Chinese Sugar Cane head, from N. N. Hartwell, La Harpe, Hancock Co., Ill.

IMPLEMENTS, ETC.—Model of Halsted's Corn and Potato Marker, from A. M. Halsted, Rye, N. Y.....Hostetter's Big Bale Cotton Conveyer, from A. R. Hoffer, Mt. Joy, Pa....Sheep Label, H. G. White, So. Framingham, Mass.

MISCELLANEOUS.—Pair of stuffed Moles—very large—from W. F. Heins, Woodstock, N. Y.....Swan, stuffed by J. L. Bode—from Mr. Lillienthal, N. Y.....Striped Jace and Crawfish, for Aquarium, from C. E. Wheeler, Orange, N. Y.....Egg of Bramah fowl—very large and heavy, length 3 inches, breadth 2 inches, weight 4 ounces—from Jno. M. Oakley, N. Y.....Red currant wine—very fine—from Mrs. Hall, Williamsburg, L. I.....Yorktown Slingshot, from Mr. Malcolm Forbes, Yorktown, 90th Regt. N. Y. Vols.....Piece of Plantain Tree, from G. E. Willet, Caracas, S. A.....Address Printer, W.M.Doty.

The "Homestead Act."

[The following important act having passed both Houses of Congress, was signed by the President May 20th, 1862, and is consequently in full force. Its provisions are important; they are so clearly stated in the Bill as to need no explanatory comments.]

AN ACT to Secure Homesteads to Actual Settlers on the Public Domain, and to Provide a Bounty for Soldiers in lieu of Grants of the Public Lands.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress Assembled: That any person who is the head of a family, or who has arrived at the age of twenty-one years, and is a citizen of the United States, or who shall have filed his declaration of intention to become such, as required by the naturalization laws of the United States, and who has never borne arms against the United States Government, or given aid and comfort to its enemies, shall, from and after the 1st of January, 1863, be entitled to enter one quarter section, or a less quantity, of unappropriated public lands, upon which said person may have filed a pre-emption claim, or which may at the time the application is made, be subject to pre-emption at $1.25, or less, per acre; or eighty acres or less of such unappropriated lands, at $2.50 per acre, to be located in a body, in conformity to the legal subdivisions of the public lands, and after the same shall have been surveyed: *Provided*, That any person owning and residing on land may, under the provisions of this act, enter other land lying contiguous to his or her said land, which shall not, with the land so already owned and occupied, exceed in the aggregate 160 acres.

SECTION 2. *And be it further enacted*, That the person applying for the benefit of this act shall, upon application to the Register of the Land Office in which he or she is about to make such entry, make affidavit before the said Register or Receiver that he or she is the head of a family, or is twenty-one years or more of age, or shall have performed service in the army of the United States, and that he has never borne arms against the Government of the United States, or given aid and comfort to its enemies, and that such application is made for his or her exclusive use and benefit, and that said entry is made for the purpose of actual settlement and cultivation, and not either directly or indirectly for the use or benefit of any other person or persons whomsoever; and upon filing the said affidavit with the Register or Receiver, and on payment of $10, he or she shall thereupon be permitted to enter the quantity of land specified: *Provided, however*, That no certificate shall be given or patent issued therefor until the expiration of five years from the date of such entry; and if, at the expiration of such time, or at any time within two years thereafter, the person making such entry—or if he be dead, his widow; or in case of her death, his heirs or devisee; or in case of a widow making such entry, her heirs or devisee, in case of her death—shall prove by two credible witnesses that he, she, or they have resided upon or cultivated the same for the term of five years immediately succeeding the time of filing the affidavit aforesaid, *and shall make affidavit that no part of said land has been alienated and that he has borne true allegiance to the Government of the United States*; then, in such case, he, she, or they, if at that time a citizen of the United States, shall be entitled to a patent, as in other cases provided for by law: *And provided further*, That in case of the death of both father and mother, leaving an infant child, or children, under twenty-one years of age, the right and fee shall enure to the benefit of said infant child or children; and the executor, administrator, or guardian may, at any time within two years after the death of the surviving parent, and in accordance with the laws of the State in which such children for the time being have their domicil, sell said land for the benefit of said infants, but for no other purpose; and the purchaser shall receive the absolute title by the purchase, and be entitled to a patent from the United States, on payment of the office fees and sum of money herein specified.

SEC. 3. *And be it further enacted*, That the Register of the Land-Office shall note all such applications on the tract books and plats of his office, and keep a record of all such entries, and make return thereof to the General Land-Office, together with the proof upon which they have been founded.

SEC. 4. *And be it further enacted*, That no lands acquired under the provisions of this act shall in any event become liable to the satisfaction of any debt or debts contracted prior to the issuing of the patent therefor.

SEC. 5. *And be it further enacted*, That if, at any time after the filing of the affidavit, as required in the section of this act, and before the expiration of the five years aforesaid, it shall be proved, after due notice to the settler, to the satisfaction of the register of the land office, that the person having filed such affidavit shall have actually changed his or her residence, or abandoned the said land, shall have failed to occupy said land for more than six months at any time, then and in that event the land so entered shall revert to the Government.

SEC. 6. *And be it further enacted*, That no individual shall be permitted to acquire title to more than one quarter section under the provisions of this act; and the Commissioner of the General Land Office is hereby required to prepare and issue such rules and regulations, consistent with this act, as shall be necessary and proper to carry the provisions into effect; and that the registers and receivers of the several land offices shall be entitled to receive the same compensation for any lands entered under the provisions of this act that they are now entitled to receive when the same quality of land is entered with money, one-half to be paid by the person making the application at the time of so doing, and the other half on the issuing of the certificate to the person to whom it may be issued; but this shall not be construed to enlarge the maximum of compensation now prescribed by law for any register or receiver: *Provided*, That nothing contained in this act shall be so construed as to impair or interfere in any manner whatever with existing pre-emption rights: *And provided, further*, That all persons who may have filed their applications for a pre-emption right prior to the passage of this act shall be entitled to all the benefits of this act. *Provided further*, That no person who has served, or may hereafter serve, for a period of not less than 14 days in the army or navy of the United States, either regular or volunteer, under the laws thereof, during the existence of an actual war, domestic or foreign, shall be deprived of the benefits of this act on account of not having attained the age of 21 years.

SEC. 7. *And be it further enacted*, That the fifth section of the set entitled "An act in addition to an act more effectually to provide for the punishment of certain crimes against the United States, and for other purposes," approved the 3d of March, in the year 1857, shall extend to all oaths, affirmations and affidavits required or authorized by this act.

SEC. 8. *And be it further enacted*, That nothing in this act shall be so construed as to prevent any person who has availed himself of the benefits of the first section of this act from paying the minimum price, or the price to which the same may have graduated, for the quantity of land so entered at any time before the expiration of the five years, and obtaining a patent therefor from the Government, as in other cases provided by law, on making proof of settlement and cultivation as provided by existing laws granting pre-emption rights.

Preserving Fence Posts.—Fences are in most parts of the country, and particularly at the west, still a necessary nuisance, and when once has grown expensive of fencing a country has been incurred, it is a great evil to have the posts rot away so that 10 per cent has to be renewed every year. Several systems of saturating timber with metallic salts have been found to preserve it for many years, but are liable subjected to the influences most favoring decay. The use of corrosive sublimate was early suggested and the process called Kyanizing after Mr. Kyan, the discoverer of the process. Other deleter salts have been recently and quite effectually employed, particularly sulphate of iron (green vitriol), sulphate of copper (blue vitriol), and chloride of zinc, the last called burnettizing. Posts are most perfectly prepared when placed in weak solutions of the salts in air tight chests, the air being exhausted by a steam or air pump, and again let in, the pores of the wood from which the air was withdrawn, are at once filled with the solution. Timber may also be prepared in open tanks by using very dilute solutions and gradually increasing the strength, from 1 to 3 pounds of the salt to 10 gallons of water. (See also p. 198.)

Containing a great variety of Items, including many good Hints and Suggestions which we give in small type and condensed form for want of space elsewhere.

Note to Crop Reporters.—Each one who furnishes a report will greatly favor us by putting the *Register number* which is in the first column of the table against his report, on the face of each blank returned.

The reports generally were received in good time, but a few came too late, and several we were only able to insert on account of a delay caused by the Strawberry Show. Some reporters omitted to give their names or residence, State, County, etc. Such reports are useless.

Full notes of prominent crops not named in the blanks, carried out in figures like the others, are very desirable.

Strawberry Premiums.—It is hardly necessary for us to direct attention again to the Strawberry Plants we offer on page 224 as Premiums for subscriptions to the *American Agriculturist*. A better opportunity to secure plants of these famous varieties can not occur.

Agriculturist Strawberry Show.—We have delayed our issue a little to be able to tell our readers about the Show of Strawberries at the Office of the *Agriculturist*, and can briefly report a most gratifying success. The Exhibition was large, the number of varieties very extensive, including many *very* valuable seedlings, and the size and quality of the fruit unsurpassed. Probably all kinds are a little larger than usual, owing to the cool, cloudy weather and rains, but this has added to their size. The principal exhibitors are Messrs. A. G. Marshall, Poughkeepsie, N. Y., 52 varieties. Prince & Co., Flushing, N. Y., 65 varieties, (not early enough or of sufficient quantity each, for competition.) Mr. Wm. F. Heins, Woodstock, N. Y., (amateur) 22 varieties. A. S. Fuller, Brooklyn, N. Y., 10 varieties, including 4 choice seedlings. E. Williams, W. Bloomfield, N. J., 28 varieties. J. Drummond, gardener to Mrs. J. H. Strong, Newtown, L. I., J. B. Colgate, Glenwood, Mr. Pell, N. Y. Orphan Asylum, William Shaw, and J. C. Thompson, both of Staten Island, besides many others showing less than 4 kinds each. The Show of new seedlings was especially fine. Our next number will contain engravings of some of the most notable kinds, and a full report. The awards made by Dr. I. M. Ward, of Newark, P. B. Mead, Ed. Horticulturist, R. G. Pardee, New-York, and Lowell Mason, jr., Orange, N. J., were as follows:

PREMIUMS AWARDED.

Largest Number of approved Varieties. E. & G. Marshall, Poughkeepsie, N. Y. $10

Second largest do., Wm. F. Heins, Woodstock, N. Y. $5

Best dish of Market berries, Wilson's Albany, E. & G. Marshall, Poughkeepsie, N. Y. $5

Best dish for General (Family) Cultivation, Triomphe de Gand, A. S. Fuller, Brooklyn, N. Y. $5

2d. do., Ward's Favorite, W. H. Goldsmith, Newark, N. J. $3

3d. do., Longworth's Prolific, Wm. Shaw, Clifton, S. I., N. Y. $2

Best three largest berries of one variety, (Triomphe de Gand,) weight 2 ounces, Wm. F. Heins, Woodstock, N. Y. $3

Best New Seedling. (Brooklyn Scarlet.) A. S. Fuller, Brooklyn, N. Y. $3

2d. best, (Large, high flavored and handsome), No. 8 B. W. A. Burgess, Glen Cove, N. Y. $2

High Commendation of No. 8 C, for size, good quality, and productiveness. W. A. Burgess, Glen Cove, N. Y.

Best Quart White Strawberries, Bieton Pine, John Drummond, Gardener to Mrs. J. H. Strong, Newtown $2

Best Quart best Flavored, Seedling No. 8 D. W. A. Burgess, Glen Cove, L. I. $2

Best Quart Triomphe de Gand, W. F. Heins, Woodstock, N. Y. $1

Best Quart Hooker, W. H. Goldsmith, Newark, N. J. $1

Best Quart Hovey's Seedling, $1.—Not awarded.

Best Quart Victoria, J. B. Colgate, Glenwood, N. Y. $1

Best Quart Wilson's Albany, Wm. Shaw, Clifton, S. I., N. Y. $1

Best Quart Jenny Lind, John Drummond, Gardener to Mrs. J. H. Strong, Newtown, N. Y. $1

Best Quart Vicomtesse Herlaent de Thury, E. & G. Marshall, Poughkeepsie, N. Y. $1

Agricultural College Act.—Congress has finally passed an act by a generous majority, giving to every State 30,000 acres of land for each Representative and Senator in Congress, according to the apportionment by the census of 1850, conditional to the acceptance of the grant by any State within two years, and the founding of at least one College where Agriculture and the mechanic Arts shall be the leading studies, not excluding others. We shall have more to say upon this Act. A similar bill has been before Congress for some years, known as the Morrill Bill, and the honor of having carried this through belongs to Hon. J. S. Morrill, of Vt.

Dyed in the Wool—A Curious Phenomenon.—Through the kindness of the Editor of the Pontiac Jacksonian, we have received a sample of Merino wool, of good quality, clipped from a pure blood Merino ewe, owned by Mr. Robt. Perry, of Oakland Co., Mich. This wool is remarkable for growing of different colors. The outer end of the locks sent is dark brown (what would be called *black*), ½ inch—then ½ inch is white, next about 3-16ths black, white, black; then follows nearly ¾ of an inch of white, and following this fully ¾ of an inch of jet black, then ¾ of an inch of white, followed by a slight shade of black, which was the growing color at the time the lock we have was clipped. The entire length of the wool is 2½ inches. The black is the healthiest wool, having the best curl. This interesting phenomenon should receive skillful and careful investigation, that the cause may be known. It is no accident.

To California Subscribers.—With this issue our subscribers in California, Oregon and Washington Territory, will commence receiving the *Agriculturist* by the steamer. This we hope will insure regularity and certainty of delivery. Since the newspaper mails have been made up for the overland route, we have had continual complaints of a failure to receive our journal. The fault has been not in the issue our own, but we are willing and desirous to supply missing numbers, and will do so to all who notify us. It is gratifying to know that notwithstanding the irregularities of the mails, our Pacific list has been well sustained, and we now hope, with regular newspaper mails, soon to address a still larger audience on those peaceful shores and among the wine and gold bearing hills and valleys.

Per Steamer to California.—A number of inquirers ask for information respecting the California Steamers, etc. The only regular line of Steamers now leave this port for the Isthmus on the 1st, 8th, 16th and 24th of each month. Time through to San Francisco, 21 to 23 days. The through fares vary from time to time. They are now: In Deck State room, $225; First Cabin, $200; Second Cabin, $150; Steerage, $100. For further particulars, fares at any time, etc., address only D. B. Allen, No. 5 Bowling Green, N. Y. City.—*and don't buy tickets of any other person.*

Rogers and Gest's Ammoniated Superphosphate.—NOTE FROM DR. PUGH, to the Editor of *American Agriculturist*.—DEAR SIR,—The manufacturers of the above manure, fear that what I have written you in relation to it, will lead the public to suppose that they sent me the first specimen we analyzed (worth about 3 times as much as the last), with a view of having me attach a higher value to their manure than it deserved. It is but just to them to say that previous to the publication of the first analysis, I never had any communication with them, nor did they know anything about our intention to analyze their superphosphate. EVAN PUGH.

Agricultural College, Pa., June 24, 1862.

Wines—American and Foreign.—It is certain that a very much larger quantity of wine is sold in this country than grows or is imported. Great quantities besides of the juices of other fruits, cider, currant wine, blackberry wine, huckleberry juice, etc., are used as the bases of imitations of wine, and sold and drank as such, to put no estimate upon the quantity of the very deleterious compounds of logwood, sugar of lead, and alcohol with other drugs, made to look and taste like port, claret, etc. Moreover, in the wine growing regions of our own country, the fact is notorious that all the bodies of sugar and water to the expressed juice or to the pulp and skins of the grapes, are of a character to double or triple the products of some vineyards. Wine will be used, and any facts which will prevent the public from being made known. Stringent laws would be equally advantageous to the importer, producer, and the consumer.

Tool Chests.—See premium list in March and April Nos. We take pleasure in directing attention to these valuable premiums. They are from the factory of Geo. Parr, of Buffalo, N. Y., and are well worth the trouble of obtaining as a premium. How much labor is saved by having an implement at hand to do any little matter at the moment—irrespective of the satisfaction of being able to accomplish it without the aid of a mechanic, and it is of inestimable value to any boy to have a knowledge of the use of tools a part of his education. How many shall we send out before the long Winter evenings are upon us? Forty-three subscribers for a $20 tool chest, and a smaller number in proportion for chests of less value.

The American Pomological Society holds its 9th biennial session in Boston, beginning on Wednesday, Sept. 17th, at noon, to continue several days. The biennial fee for membership is $2. Delegates are invited from all State and other Horticultural and Agricultural Societies. The catalogue of fruits is to be revised, and all intrusted with making reports for their localities are requested to forward them without delay to Mr. P. Barry, Rochester, N. Y.

Fancifully Colored Fruit.—It is a practice in Austria and some other parts of Europe to put various arrowroot and similar fanciful designs upon fruit. It is done by cutting the figures out of opaque paper, and covering the ripening fruit with the paper. The parts of the apple or pear exposed to the light will take the natural blush or red color, while those shaded by the paper become quite white, or light colored. Such fruits, if the designs are beautiful, bring large prices.

Which is the Best Botany?—"J. W. H.," Middlebury, Mass., without doubt "*Gray's Manual*" of botany is the best for students or for a hand-book. It is accurate, contains more plants than others, the names are spelled rightly, the descriptions are clear, mere varieties are not magnified into species, and so far as concerns the flora of the Northern United States east of the Miss. River, Virginia, and Kentucky, it is very complete. A new edition has lately been published by Ivison & Phinney, New-York, in which, besides other important and valuable addenda, 96 pages are added to the exotic plants of the Farm, Garden, shrubbery, lawn, and green-house. Bound in the same covers is Gray's first lessons in Botany. Price of the whole, in one volume, $2.25.

Salt-water Manure for Cabbages.—A farmer who has tried it, states that a weak solution of salt-water—about fifteen grains of salt to each pint of water—sprinkled upon growing cabbages two or three times a week, improves them materially, especially in heading, rendering the heads more solid and heavier.

Growing Celery.—A subscriber succeeds marvelously by raising it in a spent hot-bed—plants five or six inches apart—sides of bed deep. Water as the plants need, and trim the tops three times during Summer. They are blanched in a box in the Winter by moving in the cellar and covering the plants with dry dirt.

Seeds, Plants, & Cuttings by Mail. The law is one cent an ounce, or any fraction of an ounce—for fifteen hundred miles—ten cents for greater distances. Eight ounces is the limit of the package that may be sent. If the Postmaster makes a fuss about sending grafts and seeds, his neighbors should write to headquarters. Uncle Sam is ready to help them.

Peach Culture—Information Wanted.—There is great need of more information on the culture, diseases, etc., of this luscious fruit. We offered a prize for the best essay, but have received nothing of sufficient value to be published as a prize article. We solicit information from those who can speak from experience and observation.

Strawberry and Fruit Culture.—"E. McC.," Ohio. The business will pay anywhere, if there is a good market, and skill in the cultivator. The business grows upon one's hands generally after it is started. The beginner will of course have to pay for his education, and this item must be taken into the account in estimating the profits of the business.

To make Vines Fruitful.—Melon, cucumber, squash, and other vines of this class, are often rendered more fruitful by the pinching-in or shortening-in process. Pinch off the ends of the longest, and thus throw more strength into the lateral, bearing branches.

Cranberries.—"B.," of Cumberland, R. I., has an acre of meadow, with muck from eight to sixteen inches deep, underlaid by stiff clay, and wishes to change it into a cranberry patch, at the least expense. There are various ways of doing the thing. The muck should not be removed. If situated so that the meadow can be flowed in Winter it is desirable, though not essential. The present vegetation may be killed by draining, or by cutting with potatoes a year or two. Cut a ditch quite around the edge of the swamp. When the sods are decayed and the surface is free from weeds and grass, plant the vines in rows, and cultivate a year or two until they get full possession. They can be planted in the grass in sods, but it would be a long while before they would cover the ground. B. should visit a successful cranberry grower in his region—E. Bagley, of Usquepaug, R. I., for instance.

Pegging down Roses.—A writer in the Gardener's Monthly recommends the pegging down of moss and other roses, so as to cover the ground with their foliage and flowers. With some sorts the effect is very fine, and the bloom fuller and continued longer. It is a little harder to keep the bed clean and the ground loose.

Honey Locust Hedges.—From what we have seen of this plant put to this use we do not favor it, except for a farm fence, and for this purpose its roots run too near the surface. If well trimmed, forced to branch low, and not allowed to take the table-top shape, which is the natural habit of the tree, it will make a coarse, stout hedge. It needs light and air, otherwise the leaves fall and the small branches die; and the danger is that eventually only the tops will live. On this account it must be planted quite open.

English Hedge Plants.—"B. C. C," Ohio. Hawthorn and Privet both grow in this country, but do not do as well here as at home. They grow ragged early. The seed is generally for sale at the large seed stores in cities, and sometimes at nurseries. The evergreens, Arbor Vitæ or Hemlock, make a better hedge.

Grafting, Budding, Striking Cuttings, etc.—"G. H. F. W.," Ill. You will find full instructions upon these topics in back numbers of the *Agriculturist*, also in Downing's, Thomas', and Barry's works on fruit culture, and in most works on gardening. See also page 209 of this number.

Seedlings of the ungrafted apple and pear are generally considered more hardy, but both are extensively planted to raise stocks for grafting and budding.

Dwarfing Apples.—"D. O. D," Mo. The Paradise stock can be had of nurserymen with the apples already budded upon them, or not. They are of no use except for this purpose, and it would be hardly worth while, except for curiosity, to graft the Paradise upon the crab apple.

Currants as Trees, are usually trained from cuttings. They need frequent pinching back, and constant care while growing to keep them in this shape.

Low Limbs on Fruit Trees.—The highest which the first limbs should come out will depend something upon the aim of the fruit grower. If the ground is used for any thing else, the limbs must be up out of the way of the cultivation. If fruit alone is the aim, we want very low limbs. The ground and the trunk of the tree is better shaded, the fruit less exposed to the winds, and more easily picked. There are many advantages in low limbs.

Fruits Abundant.—We do not recollect when strawberries have been so plenty and so cheap—10c. per quart. An abundant crop of cherries is ripening, while the peach, apple and pear trees are loaded with green fruit. Whatever may be said of other crops—and they generally promise well—we are at least having a fruit-ful season. Don't forget the bottles intended to prong the fruit period indefinitely.

Goats for Milk.—The milk is good, but small in quantity. Goats are generally kept by people who are careless of their neighbors convenience and comfort. They are destructive to all trees and shrubs, and should not be allowed in the streets in any civilized community. If a man has a bush pasture that he wants cleared up and buys goats he will not have to buy bush scythes. If he wants milk, buy it, or buy a cow.

Relieving a Horse Stung by Bees.—J. L. Gibbs thus describes, in the Stock Journal, his treatment of a horse badly stung by the enraged bees of a hive he had just upset. The horse was in an agony of madness, rolling upon the ground and screaming in a frightful manner. A rope was thrown over his head to secure him, and, after administering chloric-ether, he was covered with lime water and linseed oil—which afforded immediate relief. A purge the next day, when fever was apprehended, completed the cure.

Cure for Scours in Pigs.—E. B. Lewis, of Morris Co., N. J., says he cured this disease in August pigs with strong tea made by boiling red cedar twigs.

Sheep Labels.—A subscriber (name not given), in Essex Co., N. Y., asks information about sheep labels, described on page 173. The labels may be obtained of any tinner or coppersmith, or may be cut out of sheet copper, by shears or punches. We see no necessity for their being round, but they might be triangular, square or oval; the rings may be obtained at any good hardware and cutlery store, or, for aught we see, well-annealed wire would answer nearly as well.

Stock-Raising in Texas.—We know of no work devoted exclusively to stock in that State. The standard treatises, Youatt, Skinner, Randall, etc., would be available to any one who wishes to raise cattle there.

Grape Vine Flea-Beetle.—This is a glossy, steel-blue colored insect which makes its first appearance early in May, and eats into the fruit buds. A second brood appears in the latter part of July. Watch for and destroy them. Crushing is a sure method, but perhaps dusting the vines with lime when wet with dew, will be effectual. Showering with an alkaline solution made by dissolving one pound of hard soap in twelve gallons of soap-suds after washing, is also recommended.

Peach Borer.—"R. J. C.," of Va., recommends piling small stones around the stem of the tree.

Another Remedy against the Borer.—Like those weeds which thrive best when trampled most, the borers still live. Let us not despair of preserving our trees against this vexatious foe. The Editor of the Gardener's Monthly mentions that a friend, who is famous for his success in fruit-culture, especially in growing large crops of the finest apples, informed him that the secret of his "good luck" consisted in "keeping away the borer." To do this he says: "I merely keep the soil scraped from the trunk down to the bare roots, Winter and Summer." His argument in favor of his management, is, that the borer requires moist, soft bark for its operations, and that the removal of the soil from the trunk of the tree, rendering the bark firm and hard to the collar, instinctively causes the borer to select a more favorable place for development. The treatment thus described was successful: the trees were untouched by the borer.'

Rose Bugs on Grape Vines.—Whale oil soap, 4 lbs to a barrel of water, applied with a syringe, destroys most insects. We suggest it for the rose bug.

Curculio Remedy.—In the recipe which we copied, ¾ lb. was probably mistaken for ½ pk. The water should have all the lime it can take up, and for this purpose a pound is as good as a peck. The strength of the tobacco water we have never found necessary to measure very accurately, using a pound or two of cheap, damaged tobacco, to four gallons of water.

To Kill Bushes.—(Robert.) Doubtless the mid-summer is the best time. Not because of the passing overhead of any particular star or constellation; not because the moon, new or old, exerts then any occult influence; but because the bushes are then in their most rank and succulent state, and if cut off then, close to the ground, they get a hard shock, from which they do not easily recover. It is well, also, to scatter salt profusely over the stumps, so that some of it may fall into the hollow stalks, and so kill out the roots. The salt, moreover, will attract the cattle and sheep there, whose constant browsing will serve to check any subsequent growth. Grubbing up the roots by hand is the surest method.

Burying weeds, etc., with the Plow.—"J. C. K.," of Saratoga, recommends hitching a chain to the cutter, and the other end in the staple of the whiffletree of the off horse. The loop hanging down will lay all weeds and grass flat so that the plow will bury them. This is the common practice of all good farmers.

To Destroy Canada Thistles.—Mr. A. J. Wanzer of Fort Plain, sends us the statement that he tried the following recipe or direction with entire success: "Cut Canada thistles the second day after the full moon in July." He had an excellent crop on half an acre of land, and mowed them down on the day designated one year ago, and now they have entirely disappeared. We do not believe that the moon has any thing to do with it, but from this assurance that nothing else was done it appears that at a certain period of their growth (probably, if not interfered with earlier in the season) they are peculiarly vulnerable, and this period occurs sometime in July. Let who ever believes in the moon's influence try mowing a few every day for a week before and after the magical second day after the full moon.

Grass in Fish Ponds.—"T. M. P.," of Ind. If the grass or water weed springs from the soil, the evil may be remedied perhaps, by draining off the water occasionally, and cleaning out the mud. The mud would pay for cleaning out, aside from the benefit to the water.

Eggs Cheap—Lay up for Winter.—Fresh eggs are now very abundant and cheap in this city; they are selling here for 8 to 10 cents per dozen, and of course much lower in the country. They are a nourishing, cheap food, easily digested, and are good not only alone, but when used in a great number of cooked dishes, and especially in all kinds of cakes, etc. A large stock may be put up for winter now while they are plenty and cheap. Coat with wax, or lard, or anything to keep the air from entering through the shells, and store in a cool place. They may be kept in lime, as noted elsewhere.

Pie Plant Sauce.—A lady subscriber says it is not necessary to peel the stalks. This is true, we know of the Linnæus and other thin-skinned varieties. But all kinds have not so delicate an external membrane.

Filling for the sides of a Hot-House.—"L. M.," of Brownsville, N. Y., wishes to know the comparative merits of brick and tan. Brick makes the more lasting wall. Tan will attract moisture probably quite as much as the brick and will soon rot the boards that contain it. It would, however, last a few years, and if lumber is cheap it may be economical to use it for filling.

Best Shape for Drain Tiles.—E. Crosby, Gratiot Co., Mich. Round tile, simple cylindrical tile, are preferable, being less expensive, and more easily adjusted. Sole tile, that is, tubes with a flat piece on the lower side, are extensively used, but are not so desirable. The use of collars with round tile is very desirable, but considerably increases the cost.

Water Lime.—"N. H." of Absecom, N. J. This article is known in the market as cement, and costs about the same as common lime. It can be had at Newark, and probably at "the store" in your nearest town.

Preserving Posts—A Suggestion.—In most prairie regions lime, water-lime, sand and gravel are cheaply obtained. We think posts properly set in grout—made by taking equal parts of lime and water-lime mixed with the right proportion of sand for good strong, rather thin mortar, then filled with as much clean gravel as it will bear—would not only be preserved by the lime but would stand nearly as firm as though set in large boulders imbedded in the earth. Large post-auger holes two feet deep would be large enough, and yet would not need much material. The post should not touch the ground and the cement should be drawn up around it so as to turn water.

Coal oil to soften Putty.—"J. A. G." of Waverly, N. Y., recommends this article, and says it is effectual. If so, coal oil is now so common that it will prove a very convenient article for this purpose and save much labor in repairing old windows.

Coal oil for Oil Stones.—For this the same person also recommends it. It does not gum in warm weather nor freeze in cold, and sets a good edge.

Skunk Odor.—"L. P." of Coldwater. The bouquet is of unparalleled pungency and sticks closer than a burr. Burying the garments in the earth, or in fresh burned charcoal, are the best remedies we know of. They should lie several days.

Raising water by Pipes.—"T. J." of Michigan City, Ind. The cheapest mode of raising water and supplying a few families, would be by the water ram and lead or iron pipes. The pressure will be too great for cement. The size of the pipes needed will depend upon the quantity of water it is desired to raise, and the hight. See this subject illustrated in November 1858.

Cobble-stone Pavements.—"H. S. I" Woodbury, Conn.) They are made by filling in a bed of sharp sand to about half the thickness of the stones of the level you desire the pavement to be. The depth of this bed of sand is according to the soil—on a firm gravelly or sandy soil it need be but just thick enough to give a bed to the stones; on loamy loose soil considerably thicker, and perhaps underlaid with a layer of flat stones and gravel. When a suitable bed is prepared, stones of a uniform size (at least the exposed ends to be uniform) are selected, and then the stones are placed partially buried in the sand and rising one or two inches above the desired level. The work is done by means of an adz-shaped tool by which the sand is scooped away and the stone tapped down firmly. When some square yards are set, the stones are settled by means of a heavy pounder made of a sound hickory stick, 8 inches thick at the big end, 3 feet long with an upright handle in the top and one at the side; and finally, fine sand is swept back and forth over the pavement until all the cracks are filled.

Influence of the Moon on Vegetation.

Superstitions die hard. Men have a natural love of the marvellous. The simple truth don't satisfy. We like to be imposed upon, and not content with this, we impose upon ourselves. An instance of this appears in the various notions in vogue respecting the influence of the moon. Here are a few of them:—The rays of the full moon falling upon a pan of milk will turn it sour. The light of the moon produces a chill. Purgatives for children operate only in the first quarter of the moon. Pork will shrink badly, if killed in the wrong quarter. Peas planted in the first quarter will run to vines. Hemlock bark peels easily in the new, but not in the old of the moon, in August and September! We have read of a man who "*knew* that hickory cut in the new of the moon was safe forever from worms, for he had tried it"; "Safe *forever*, for he had tried it." Venerable old man! you have plucked the honors from Methuselah.

The moon, so the astronomers show us, is at a mean distance from our planet of 240,000 miles—sometimes a little farther off (apogee), and sometimes a little nearer (perigee). It revolves around the earth once in twenty-seven days, but, on account of the daily revolution of the earth on its own axis, the moon appears to go round us once in about twenty-five hours. It appears larger at one time than another, but this is only because the sun then shines upon more of that portion of the surface which we see. The same quantity of matter revolves around us at the first quarter of the moon as at the full moon, only we do not see it.

Does the moon, then, affect us by attraction? This acts on all matter alike, and it diminishes inversely as the square of the distance. The influence of the moon's attraction must be nearly uniform and constant, not dependent on the mere fact of its giving light or not. As it passes over us every day of the year, at nearly the same distance, why should not its attracting power be about equal every day? Yet people never think of the moon's power when it is not visible. Consider, too, its comparatively small bulk—only about one seventieth the quantity of matter of our globe—and its immense distance from us. Is it supposable that its attracting power can influence the rise and fall of the sap in vegetables, or the flow of blood in animals?

Still, it can not be denied that the moon produces mechanical effects on our globe. Its influence to a great extent causes the tides of the ocean. Yet it does not sensibly affect the surface of our lakes and rivers; and if it does not influence those great inland seas, is it likely that it affects the juices in the stalks of peas, or the sap in hemlocks?

But how about the influence of its light? It has no light of its own, but merely reflects that of the sun; so it is sun-light after all. How powerful is it? There is, according to M. Borguer, a French philosopher, only 1-300,000th part of the illuminating force in it that there is in the sun. Surely, only a little effect can be produced by that. Yet, as stated by Dr. Lindley, (see last edition of his "Theory of Horticulture,") a very slight effect has been detected by a French naturalist, on the delicate leaves of the *Mimosa citiata, M. pudica*, and the *Desmodium gyrans*, the first being raised four-tenths of an inch, the second about an inch, and the last exhibiting slight vibrations. These plants are very delicate and sensitive in their organization, and it would not be wholly impertinent to suggest that possibly these effects were produced, accidentally, by the artificial heat or lights of the green-house in which the experiments were performed, or by the bodily warmth of the operator, or by currents of air from open doors or windows. But, at most, the effect of the moon's ray is so slight on ordinary plants as to be entirely imperceptible, and of no practical account. An astronomical professor at our elbow observes that the reflection of light from a white cloud by day is stronger than that from the full moon.

As to the heat of the lunar ray, no great claim will be set up for it by any body. Indeed, our friend was about right when he affirmed that the moonlight chilled him. Experiments have been tried with the most delicate thermometers, and not the least impression was produced.

On the whole, we can not find that these moon-struck people have much beside moonshine in their theories. Those with whom we have happened to talk, seemed about as serious and wise as the farmer who gravely said: "And I allers took notice, in layin' stun-wall, particularly in the full o' the moon, that the foundation stun allers cum next to the ground!" *

For the American Agriculturist.

Spare the Birds!

A certain New-Hampshire poet is hard upon bird-shooters. He declares: "You have lived too long already. Instead of marble, you deserve a white birch slab, with this epitaph:

> Here lies at rest, a worthless pest,
> Who had no soul to lose or save;
> And these four words——*He killed the birds*,
> Proclaim his worth who fills this grave."

Well, I have myself said similar things in the days of my inexperience, but just now, smarting under many sufferings, beg to sing a different song. What thieves some of the birds have proved to be! Having won our affections they took great liberties with our property. Our strawberry beds, filled with the choicest new varieties, and just coming into bearing, were their first plunder. Whistling at them, and shoo! shoo-ing, did no permanent good. They thought it only one of our amusements. We then set up all sorts of scare-crows, old coats, hats and bonnets of former generations, rattling wind-mills, pieces of glittering tin, and such like terrific things. They answered well for a day or two; but after that the robins came and perched on the scare-crows, and revelled among the berries again! We next tried throwing sticks and stones, until we were all tired and our patience clean gone entirely.

Well, tenderness of heart and sentiment ruled, and the robins were allowed to take the better part of our strawberries. Next came the raspberries, and the robins likewise, and very hungry. We scolded, and threw sticks and stones, but to little purpose. The birds got most of the ripe fruit. We couldn't hurt the sweet songsters.

Last of all, came our grape-crop. Robins like good grapes. They coincide with the cities, that Delawares and Rebeccas are our best grapes, very toothsome, easily digested, may be eaten in large quantities without disagreeable results, etc., etc. An occasional stick or stone flying about their heads is a very trifling affair. Loud talking, and all attempts at frightening them, do not disturb their serenity. The writer of this, in a moment of passion, last Fall, loaded his gun and shot two robins from his vines, and hung their mangled bodies across the top of the trellis as an awful example to others. In ten minutes after, several robins came and sat by the side of their dead companions, digesting their grapes and pluming their feathers as though nothing special had happened! Day after day the voracious birds came in flocks, and soon stripped our vines. The money loss, indeed, was not irreparable, but the disappointment and vexation—the loss of specimen clusters from many new varieties which I had watched for several years, and were just coming into bearing; lost, too, in such a cool, unappreciative way—was more than I could patiently bear.

Henceforth, I shall keep my shooting-iron in order, and loaded; and the first robin that touches our strawberries, and the last that devours our grapes, shall feel the cold lead. In all other parts of our garden, orchard and lawn, all birds shall be welcome, but in the places afore-named we shall not be responsible for their lives. FOWLER.

[The argument of brute force is effectual, but should be used only as a last resort. We think birds that have the liberty of the lawn and orchard, will not be likely to fear the cold lead that awaits them in the strawberry patch. They will fear a cat, either caged or stuffed. You can not put pussy to a better service than to guard the berries. She may be confined by a string in the strawberry patch, or in a large bird-cage among the raspberries and blackberries. A skin neatly stuffed, in the cherry tree, will frighten them away. Their instinct teaches them to shun certain natural enemies. Keep these in sight and your fruit is safe. What boy would steal pears with a fierce bull dog under the tree? A bird's instinct is as good as a boy's.—ED.]

Use of Toads in Agriculture.

Our ugly friend affects gardens as much as the lord of creation. You will find him in a hole in the wall, in the strawberry patch, under the squash vines, or among the cucumbers. He is not handsome, but serene and dignified as a judge. He executes judgment upon all bugs, worms, snails, and pests of the garden, in the most summary way. See what a capacious maw he has, occupying the whole space from his fore legs to his haunches. He is the very incarnation of stomach, and his gastronomic feats would do credit to an Alderman. He tucks away bugs and all kindred flesh as an epicure would turtle and pudding. He is never full. That maw stretches like caoutchouc, and he is nearer having an endless gullet than any reptile. He is altogether too useful to be without enemies. All the serpent tribe hate him and devour him when they can. Even man slanders him. He misses a few strawberries from his patch, and lays it to the toad, who stands like a sentinel guarding his treasures. It was the snail who did the mischief before the toad took up his station; fortunately he is now where he will spoil no more ruddy fruit. Or it was the robin who slyly snapped up the berries and flew off into the neighboring tree, leaving the poor toad to bear his sins. But you see by the look of his honest face, that he is guiltless. Those lustrous eyes are above stealing. One fat bug would give him more pleasure than all the fruit in your garden.

Cultivate the friendship of toads, for they take the insects that the birds are apt to overlook. They inspect the ground closely, peer under the leaves of strawberries, under the growing vines, and nab every creeping thing in sight. They are as easily domesticated as birds, never sing when you do not want them to, are quiet and unobtrusive, and if not worth five hundred dollars a piece, are still profitable pets and fellow-helpers. Birch the boy that teases toads.

The Agriculturist Crop Reports.

Breadth, Condition, and Prospects of the Growing Crops in 24 States and Territories. Gathered from 1,557 Reporters.

On pages 218 and 219 will be found, in compact tabular form, the reports on the growing crops for June 10th. A considerable increase in the number of reports over last month will be marked, and some important changes. We are free to say that no system of gathering statistics in this country, (*even that attempted* recently by the Patent Agricultural Office,) has given so satisfactory and truthful an exhibit of the state of the crops, even over a very limited district, as we present in these reports for the whole country, where war is not actually going on. Drouths have continued in some sections since our reports came in, which were then severe, and in parts of Illinois the newspapers report, in a few cases, great damage to the wheat by the midge and chinch bug, but of this we have no direct report, and do not believe extensive damage has been sustained by the crops.

PROSPECTS.

Winter Wheat promised, on June 10th, well in all the great wheat region of the West, and below an average only in New-England and Kentucky. We have reports of injuries to the crops by rust, and insects, or by both, from a few counties in Ohio, Indiana, Illinois, and Iowa, but in few cases only are they very serious.

Spring Wheat has been affected quite unfavorably by the cold rains, frosts, and drouths.

Indian Corn.—Our great staple, upon which also depend the beef and pork product, is, we regret to say, a little "under the weather" yet, still June settles the fate of the crop, and that was only one-third passed when our reports were made out, and the season besides was nearly 10 days backward.

Rye, following in the wake of careless wheat farming, is chiefly reported upon in the older States, and hardly comes up to average promise.

Oats almost everywhere have been seriously affected by the unfavorable weather of all kinds —planted late, they have suffered equally from cold and drouth where they prevailed.

Hay.—The grass crop seems to have sustained itself well—no where below average in promise except in Michigan, New-England, and N. Y.

Potatoes promise decidedly better than common, except perhaps in the far West.

Fruit.—The apple crop has suffered considerably, but not enough to reduce the crop to average, or near it; and the peach crop still promises exceedingly well.

THE GENERAL AVERAGE is about 3 per cent lower than last month—the footing being **12.2.** The average prospects of farm crops (exclusive of fruit) is a little above average, viz.: **10.3** which is very gratifying.

CROPS NOT SPECIFIED.

BARLEY.—We have reports from Ohio, Wisconsin, Minnesota, the Middle and Eastern States. The mean of the estimates for surface compared with the average for 5 years is 13, or nearly ¼ more, while the prospects are accounted 11¼—decidedly better than average. Where sorghum is cultivated, barley has given way to it a little.

SORGHUM.—We have quite full reports from Ohio, Indiana, Illinois, Iowa, and a few from Pennsylvania, Minnesota, Mich. and Wisconsin. In only a single case is a decrease of surface reported—in another, an equal surface—in all taken together (70 reports), an increase amounting in the mean to nearly 3 times the breadth cultivated for the past 5 years. This must indicate a large increase over last year. In the case of this crop it would be better could we compare this year's crop with that of last year instead of the 5 years past. (If reporters follow this suggestion, will they please specify it particularly.) The prospects of the crops in Ohio and Indiana, are better than average; in Illinois, a little below, and in Iowa, just about average. The crop now promises to make itself felt in the market decidedly more than last year.

FLAX.—The reports from the flax-growing Counties of Ohio, Indiana, Illinois, and Pennsylvania, uniformly represent a much greater breadth sown than usual, and the crop above the average condition, and the same is true of scattered reports from other sections. They all foot up 2½ times as much sown, and two-tenths better prospects than usual.

HOPS.—So far as reported it appears the culture is increasing and the condition very promising at present.

PEAS AND BEANS.—These crops are reported chiefly from the extreme Northern line of States and Counties; about two-thirds more than common have been planted, and the crop does not promise well on the whole.

THE WEATHER for the month from May 10th to June 10th, has been exceedingly diverse in different parts of the country; even different parts of the same State exhibit in numerous cases the results of excessive rains, and, for the season, of unusual local drouths, while in every State larger or smaller sections have enjoyed that happy medium which is the farmer's highest joy in this respect. In New-England, and the States of Maryland, (Eastern) Virginia and Delaware, while there has been some drouth, sufficient to reduce the hay and Spring grain crop materially in sections of New-England, the weather has been on the whole, better than in average seasons. In New-York and Pennsylvania, it has been less favorable, a severe drouth being reported by many in the Northern, Western, and Middle counties of New-York, and in Western Pennsylvania, and at the same time very cool weather has prevailed in some of these same regions accompanied by killing frosts, while Central and particularly Eastern Pennsylvania, and Eastern New-York, to a less degree have suffered from powerful rains, causing freshets, etc. The season is backward every where, though where dry weather has prevailed, Spring work has been well done. In Ohio damage to crops from wet weather, floods and frosts is reported, though the dryness in some of the Northern counties has amounted almost to drouth. In Indiana, through the middle counties there has been some trouble from drouth; in the southern from wet; while a similar state of things has prevailed in Illinois. The streaks (so to speak) of wet and dry weather have taken in a measure an oblique N. E. course across the country. In Michigan there are reports of drouth and frost. In Wisconsin, cold, wet weather, drouth and frost are all reported. Iowa reporters speak of a backward season, cold and wet. The severest changes and hardest storms occurred between the 20th of May and the 1st of June, since which time the weather has been more generally dry, especially in New-England. In Maine, for instance, there has scarcely been a soaking rain since planting time, and the hay crop promises to be very light.

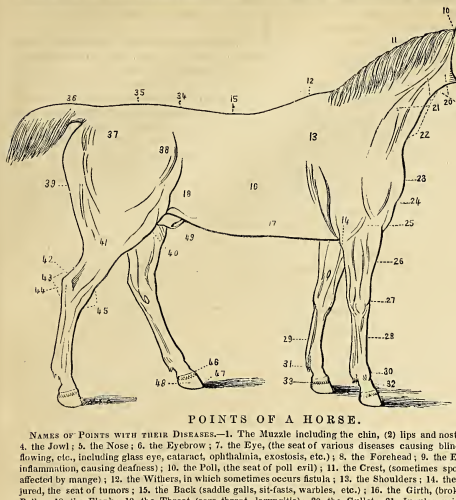
The Homestead Law.

The measure for procuring homesteads for the landless which has been before the country for so many years, has at length become a law. It will be good policy for the Government, we have no doubt, for the lands given away will be worth far more to the country, peopled with an industrious population, than lying waste as they now do. They will soon yield up their treasures of grain or of cotton and tobacco to be exported, and to buy goods that will pay a duty to the Government. Peopled, they will furnish soldiers for the army, and taxes to pay their expenses, should the country need them. Before this law was passed, lands were so cheap that every man of real energy and industry could obtain a homestead if he tried, provided he could raise the means to get on to the land. This will be the chief difficulty now. Hundreds and thousands of families to whom the land would be a priceless boon will never be able to reach it. They have little forecast, are poor and in debt, and pretty much discouraged. They can not find constant employment, and do not know how to employ themselves profitably. If associations could be formed for settling these lands in part by such families, it would meet the difficulty. It would help them, without damaging the success of the new settlement. It would secure to them at once homesteads and full employment, which they so much need.

Many questions are asked concerning this new law by those who desire to avail themselves of its advantages. A careful reading of the law, which we publish, will answer many of them. The lands are to be found in Michigan, Wisconsin, Iowa, Minnesota, Missouri, Kansas, Nebraska, Texas, and on the Pacific, in large extent, and some still in Ohio, Indiana, and Illinois, though they are probably not of a very inviting character. The lands lying along railroads are of double price, and on account of the proximity to market, are perhaps cheaper at that rate. Only eighty acres of these can be taken by one individual.

The old pre-emption laws are still in force, and a man may locate his land holding by these laws until the 1st of January, when he can hold by the new law. There are land offices in the vicinity of all these public lands, where the applicant can make known his wants and secure his homestead. It will be seen that the matter involves either the expense of a personal visit, or that of a delegate, which is a serious obstacle to the poor. The best thing that can be done, probably, in all cases by those who wish to avail themselves of this law, will be to form an association for the settlement of a township, say a hundred families or more, and send out an agent to examine and locate the lands in a body. The advantages of planting a whole christian community in the wilderness at once, over private emigration, are too apparent to need mention here.

A word of counsel: A farm for ten dollars is not particularly cheap. It is the raw material of a home. Houses, barns, fences, roads, bridges, churches, school houses, and other public buildings, are to be provided after the colony is located, and these things bring heavy taxes upon every individual for a dozen years or more. A man getting a living at the East should think twice before he goes into the wilderness. It is young men just married, or about to be, men with large families and scanty means of living, and professional men with small fields of labor, that can take this step with the best prospects.



POINTS OF A HORSE.

NAMES OF POINTS WITH THEIR DISEASES.—1. The Muzzle including the chin, (2) lips and nostrils; 3. the Jaw; 4. the Jowl; 5. the Nose; 6. the Eyebrow; 7. the Eye, (the seat of various diseases causing blindness, weakness, flowing, etc., including glass eye, cataract, ophthalmia, exostosis, etc.); 8. the Forehead; 9. the Ears, (affected by inflammation, causing deafness); 10. the Poll, (the seat of poll evil); 11. the Crest, (sometimes spongy and fat, and affected by mange); 12. the Withers, in which sometimes occurs fistula; 13. the Shoulders; 14. the Elbow, often injured, the seat of tumors; 15. the Back (saddle galls, sit-fasts, warbles, etc.); 16. the Girth, (broken rib); 17. the Belly; 18. the Flank; 19. the Throat (sore throat, laryngitis); 20. the Gullet; 21. Jugular vein; 22. Windpipe (bronchitis, injury from collar); 23. Point of Shoulder (contusions, lameness, and sprains); 24. Breast or bosom, (various internal diseases, chest founder, broken wind, etc., are located within the chest cavity); 25. the Elbow Joint; 26. the Fore Arm; 27. the Knees, (knee-galls, abscesses, broken knee—by white spots showing a tendency to stumble, knock-kneed, bow-kneed, weakness of the joint, etc.); 28. Cannon bone, (splents); 29. Tendons, often spongy, knotty, and the seat of wind galls and other injuries; 30. Fetlock Joint, (the seat of swellings, osseous enlargements, stiffness, wind-galls, etc.); 31. the Fetlock; 32. the Pastern (ring-bone, fracture, wind-galls, cracking of the skin, etc.); 33. Heels, (grease); 34. Loins; 35. Croup, (occasional dislocation); 36. Dock, (injury by the crooper, and mange); 37. Rump; 38. the Hip, (bruises, wounds, and fracture); 39. Quarters; 40. the Stifle, (subject to dislocation, bruises, sprains, and whirl-bone lameness); 41. Thigh or Gaskin, (sprain, string halt); 42. Hamstring; 43 and 45. the Hock. (blood spavin, bog spavin, bone spavin, capped hock, thorough-pin, curb, etc.); 44. the Hock-bone; 46. Corona; 47 Toe; 48. Walls of the hoof, (the Hoof. the seat of numerous diseases, must be explained on another occasion); 49. Sheath, (often foul).

The Horse of all Work.

It is a difficult thing to determine exactly what should be considered a perfect horse—for the perfection of any domestic animal consists in its adaptation to the service required of it—be it ox, cow, sheep, swine, or horse. The English hunter is as near the type of a perfect horse of all work as can be found. It is particularly necessary for farmers who breed horses to study their points, particularly with reference to sires. A breeding horse should be sound in all respects, except blemishes caused by accidents or violence, or by sickness which was neither inherited nor can be transmitted. A good horse is moderately short-backed (12 to 24), and long below (17); round barreled and well ribbed up (16); rather high in the withers (12); having moderately sloping shoulders (12 to 23); a broad chest (24), a firm, and muscular crest (11), a head well set on, lean and bony, with a clear, bright, medium-sized, intelligent eye, an open, thin, broad nostril, clean muzzle, and small ears; his rump (35) should be straight, broad, and full; his loins (34) broad; legs above the knee (27) or hock (43) long and muscular. All the important muscles of the extremities are located above these points, and below them they should be short and bony, and the tendons (29) hard, and free from soft spots or exerescenses; the leg bones large, flat, and smooth; the pasterns (23) not too long or oblique; hoofs hard, clean, deep, (not flat) round (on the ground) and good sized. The knees (27) and hocks (43) should be broad and bony, the quarters (39) large, broad, and muscular, square when seen from the rear, the shanks from the hock to the pastern short, hard, and clean. A horse can hardly have too deep and broad a chest, too strait a back from withers to croop, or too thin and delicate a neck near the head. Under the cut above we give the names of the various parts, and some of the blemishes and diseases of the parts. Many diseases are only known in fancy, and almost all are known by several different names.

Shall we Spare the Crows and Blackbirds?

It is well to look at two sides of a question. We have argued even in favor of crows and blackbirds, and let our correspondent present the other side. Let the enemies of these examine the maws of their victims and report the contents, whither they be young birds, or corn, or beetles. We do not believe that blackbirds eat the young of other birds, but crows do.

To the Editor of the American Agriculturist.

Looking over the *Agriculturist* Calendar for May, I noticed the following: "Birds—Spare them all; put up bird boxes, kill cats that kill birds, allow no guns to be fired on or near the premises." Innocent birds should be protected, and a heavy fine should be paid by any one cruel enough to injure them. No one loves the sweet song of the Lark, the Goldfinch, or any other innocent or beautiful bird more than I do, but such birds as the vile crow and the more hateful blackbird I shall ever be at war with. The crow will rob the blackbird or any innocent bird it can find or catch, and the blackbird will do the same as far as it is able, and for this reason I shoot all the blackbirds and crows that I can hit with my rifle. I never shot a crow for pulling corn, but have shot dozens of them because they rob and kill innocent birds. So too with the blackbirds, I often have watched them fleeing from two or three little birds that they had robbed. It is idle to talk of saving the birds by ceasing to destroy crows and blackbirds. They are the very worst enemies that birds have. I am tired and out of patience with the almost eternal cry of "Save the crows," because, as the New-York farmers club says, they are terrible fellows to kill worms and save the corn. It is true that they will eat a few worms when they come handy and can get nothing else, but they greatly prefer larger game, and when they can find frogs, young chickens, or young birds of any kind, they never trouble themselves about the duty of picking worms out of corn hills; one robin is worth a dozen crows to kill worms, and yet the crow-savers never seem to dream that the crow and blackbird will soon exterminate these useful, innocent birds, as well as many others. As to firing guns, I would say that I shot more than any other man in the neighborhood, and I have frequently heard persons remark that we have more singing birds than any of our neighbors. The report of a gun evidently does not frighten small birds away, else none would be with us. D. W. F.

Seasonable Cultivation.

There is such a thing as thorough culture, and seasonable culture: it is of the latter we now have a word to say. Seasonable culture cuts down and roots up weeds when they are quite small. It does not wait until they have become so large as to require double the amount of time and strength to subdue them. Least of all does it wait until they have ripened their seeds and begun to scatter them on the wind. Seasonable culture tills plants at the time they will be most benefitted by it. Here, for example, is a hill of melons: the vines a foot long, and the weeds among them a foot high. Now, how long would those vines have become by this time, if the weeds had never been allowed to grow? It will not make amends to cut them down now: they should never have been suffered to grow at all. Work vigorously as you may, the rest of the Summer, you can not catch up. Here, then, is a difference between culture and seasonable culture. Consider this, too. The work of digging out such large weeds injures the melons. The roots will be more or less broken and disturbed, and the leaves, suddenly exposed to the full glare of the sun, will wither. When the plants recover from this shock, and go on again to set their fruit, it will be considerably later in maturing, than it would have been under better management; and of course it will be poorer than if ripened in its own proper season. Does not this instance illustrate a general principle? The rule holds good of nearly all crops. They should be planted in their proper season, and cultivated at the time they most need it. Let farmers learn, if they would thrive, to till no more ground than they can till well and seasonably.

The Manure Heap in Summer.

There is danger lest, in this busy season, the manure heap be overlooked. With the tokens of fertility waving in every field, we are apt to forget that the wants of another year must be provided for. The barn-yard probably has been cleared of its winter store, and but little dung is now accumulating. Yet, that little should be carefully husbanded. As manure heats and wastes by decomposition in hot weather faster than in cold, provision should be made for saving it by the use of absorbents. At every leisure hour, the farmer's team would be well employed in gathering up sods, scrapings of the road-side, leaves, rotten logs and stumps, and whatever else will decay, and carting the same into one corner of the barn-yard. Indeed, it should be a standing order for every member of the household to save and gather up everything that may answer a good purpose in the compost heap. How a heap will grow, when every one contributes something to it! With a pile of absorbents near at hand, they will be used. The liquid parts of the manure will be taken up, and the solid parts prevented from fire-fanging. Let these various articles be worked over, half and half, and the whole bulk will be worth as much as the same amount of simple manure. By Autumn, there will be a fine provision for enriching the grain-fields and for top-dressing grass lands.

A few Words for Muck and Peat.

Some persons who seem to question the usefulness of these articles, would hardly continue to doubt, if they considered well of what they are composed. They consist largely of half decayed vegetable matters which grew long ago on the spot, or were washed in from the adjoining high lands. Being covered up, layer upon layer, their decomposition has been quite slow. They also contain certain mineral elements which have leached in from the surrounding soils. But, aside from these fertilizing elements, peat and muck when dry possess great attraction for ammonia. Absorbing this from liquids and half solids, they store it up for the food of plants to which it may hereafter be applied.

Now, when we walk over a farm on which the high lands are light and nearly exhausted of their fertility, and yet find in the low lands deposits of peat and mud and muck, is it not a plain case that this farm is in a measure upside down, and ought to be set on its feet again? Some of its fertility, no doubt, has been carried off in the crops raised and sold, but much still remains behind, though down in the bogs and swamps. It has been traveling down hill perhaps for centuries, yet with so slow and silent a step that the farmer has not noticed it. The laws of nature have carried down the fertile elements, but theory will not bring them up again. Man must do that. Here is a field for his ingenuity and industry. His lands are not wasted beyond recovery, if he will only bestir himself and follow the hints which nature gives him.

Doubtless, it would not be best to apply this peat and muck in the crude, "sour" state in which it is first dug from the bed. Let it have the ameliorating influences of heat and air, and perhaps of frost. Spread it in large, long heaps on the uplands. Mix it with lime or fresh ashes and let the heap lie several months. Or again, dry it, and afterwards cart it under a lean-to of the barn, where it may be used to absorb the liquids of the stables. Then spread it on the hungry fields, and they will clap their hands for joy, and the hills will be joyful together.

Spontaneous Vegetation.

To the facts mentioned by our correspondent SCHOLASTICUS, on page 178, a multitude might be added from almost every farmer's observation. Clear up a piece of woodland, and a new class of trees comes in—very rarely the last that occupied the soil. Burn it over, and very likely raspberries, whortleberries, and mulleins will start up, though these plants have never before been seen within miles of the place. Throw up mud and peat from almost any swamp, and let it lie a year or two, it will be covered with vegetation unlike that in the immediate vicinity. How do we account for these facts?

Men of skeptical minds jump to the conclusion, that they do not grow from seeds, because they did not see them planted, and from the known circumstances they could not have been planted in their day. They think the soil must have the power of spontaneous generation, and of course infer that the world made itself, and all living things began their existence spontaneously. There is no need therefore of a Creator.

We have no evidence in these, and kindred facts, that every plant does not spring from seed. It is a well known fact that the surface of the earth, far below the ordinary depth disturbed by man, has been subjected to very great changes. Surface soil filled with seeds of all kinds of grasses, herbs, shrubs, and trees, has been commingled with the soil away down in the depths of the earth to the solid rocks, often many thousands of feet below the surface. The agencies which have done this are still in force. Earthquakes, volcanoes, floods, land-slides, etc., are the more obvious causes, because violent in their operations, but the trickling rills on the mountain sides, and the constant flow of many waters toward the sea, taken in connection with the never ceasing action of the tides, effect much more. The Mississippi River and its tributaries are displacing many acres of soil, loaded with seeds, every day. Seeds produced in the Rocky Mountains, by this agency, find their way to the Gulf, and are spread all over the Delta. Some lodge on the surface of the overflowed land, and germinate with the subsiding waters. Others are buried at different depths, clear to the bottom of the Gulf, and may be thrown up by the diggers of wells, and Artesian borings, hundreds of years hence, to astonish the natives with strange vegetation, and the "creative" powers of the soil. No casing has ever been invented so good as the soil to preserve seeds. No man can tell how long seeds will keep well in it.

What is going on, on a grand scale in the great valley, is going on along the banks of every rivulet and brook. The running water is all the while transporting seeds, and depositing them in new localities. Every depression that gathers mud for a swamp, gathers seeds in great variety, and has been gathering them for centuries. A great many die, but enough live to cover any patch of mud or peat with a new vegetation.

Besides these agencies for distributing seeds, we have birds and animals. The seeds of many of the berries have a covering so hard, that they resist, successfully, the gastric juice of the stomach. The berry eaten to-day upon the mountain, is ejected many miles away to-morrow in the valley. Some plants, like the burdock, have little hooks attached to the seed, and are ready to fasten to every moving thing for conveyance to a new location. Many have wings attached to them, so that they are blown for miles by high winds. Nature is prolific with seeds, every plant producing abundantly after its kind, and almost as lavish in providing the means of distributing them far and wide.

It would be very strange if every newly exposed patch of soil did not produce new kinds of plants. Salt springs and lakes were once the bed of the ocean, no matter how far they may now be from the shore. We should expect to find plants belonging to the sea-shore, near salt springs. The bottoms of lakes, and ponds, are strewn with seeds that have been accumulating for ages. Give them light and heat, and they germinate. Seeds of white clover lie dormant for years, until gypsum, sown upon the land, or some other cause induces germination, and "brings in clover." The seeds of sea-side plants, transported by birds, or dormant in the soil, wait only the salt-water influences afforded by salt springs to start up and flourish.

Irrigation.

BY JOHN R. WOLFE, COLORADO TERRITORY.

The subject of irrigation has been discussed but little by our agricultural societies and papers; and yet it is to my mind one of the most important, not only to countries like this, where there can be no dependence upon seasonable rains, but to every country where the seasons vary from wet to dry, sometimes causing a surplus, at others, putting us on short allowance. "Give me neither poverty nor riches," but a regular and uniform supply, should be the prayer of every farmer. Fluctuation in produce must ever cause fluctuation in price—excess is not to be dreaded as deficiency; and if by any means we can prevent with certainty, any serious deficiency, we have gained the ultimatum of human effort in supplying human needs. It is well known to your readers that there are many places where the only supply of water is by artificial means. In those places crops are regular and certain. If then the same plan can be made available to any considerable extent in other countries, in dry seasons, we have gained an important point in securing a fair supply. It will be my business now, to endeavor to awaken attention to the subject by setting forth the modes of irrigation in different countries, to point out the most improved plan, and to exhibit in a favorable light, the advantages of this method of farming, even where rain is abundant.

If we go back to the early history of Egypt, we find that the flooding process was employed, as much perhaps for the fertilizing effect, as the moisture. In the early days of Mexico, the same method was adopted. This method is still practiced in New-Mexico, and has been adopted in this territory to a large extent under the administration of Mexicans employed for that purpose. But as yet, little irrigation is done here. Our farmers have contented themselves with the selection of damp spots of ground, for the main crop, and experiments on high lands without water. Nearly every such experiment has failed; and they must continue to fail until the seasons change, though there may be spots where small grain can be raised on high ground by deep plowing. I presume Egypt has not changed, but the more intelligent agriculturists of Mexico [and the rest of the world, too,] have abandoned the flooding plan; and it remains for Americans to bring methods of irrigation to the highest degree of perfection. Imperfect as is the practice in New-Mexico, the

most prodigious results are produced: onions are raised there weighing 2½ to 3 lbs.; these are from Mexican seed; the American annual onion sometimes reaches 2 pounds weight.

When the flooding process is used, all the ground is surrounded with embankments to retain the water, say 12 inches high. In these embankments there are openings for ingress and egress; the water is let on, and allowed to remain until the ground is thoroughly soaked; it is then drawn off. The result of this is the deposit of sediment, baking of ground around the roots and tender plants, and an immense amount of labor to put the ground in order again. When this plan is applied to field culture, you may calculate, if you can, the labor necessary to raise a large crop. By the time the ground is in order it is time to let on the water again, and so on through the season. This method was formerly adopted in Utah, but I am told is gradually going out of use, and much of their small grain is raised without irrigation.

The writer saw at once that this plan would not suit on an extensive scale, and that it was not the best method on any scale. He therefore adopted a plan which is destined to supersede, in this territory, the plan of New-Mexico. Grounds requiring irrigation must be so arranged that the water will flow slowly through furrows prepared for the purpose, so as to give ample time for it to penetrate the entire soil. Head and tail ditches are constructed, at convenient distances, to admit the water, and conduct the surplus to other points where needed. Corn and potatoes are easily irrigated by a central furrow made with a shovel-plow; small grains by furrows run 2 to 4 feet apart with a similar instrument. All small crops—roots, etc.—planted 18 inches apart, admit a small furrow with a hoe. Thus the water can be applied to the roots without touching the top of the plant, or causing the ground to bake. The demand for water can always be known by digging with a hoe or spade about the plants. As there is a time for all things, so there is a time for the application of water. The best rule is to keep the ground regularly moistened until the plant approaches maturity, when the supply should be diminished or cut off entirely until it is fully ripened.

It is always best to have a pool at the head of the main ditch to collect and warm the water; the same result may be obtained by a long ditch and slow motion to the water; but this is not an absolute necessity when the water is applied to the roots alone, nor is it a necessity to irrigate in the evening or night only; on the contrary, the process may be continued all day, without any apparent disadvantage. In order to avoid the evil of second growth in potatoes, or the formation of small ones on the main tuber—I select those varieties free from any such *constitutional tendency*, (the blue Meshannock is objectionable on this account.) Round potatoes are generally best. Then I would make the rows, (drills or hills), 4 feet apart, plant deep, and hill but little; then by running a center furrow, the water will be absorbed in larger quantities, the roots kept moist longer, and the growth necessarily more regular. I am thus particular about the potato, because this crop is so easily spoiled by an excess of water, becoming insipid and almost useless. Size with loss of quality is gained at a great sacrifice, and notwithstanding the immense yield and enormous size of our potatoes, but few raised in this country are fit for table use; they are generally too knotty and watery. These defects are produced by planting in low, moist, rich land, where the supply of water is too great and continued too long—until the frost kills the tops while the plants are in full vigor. It is an absolute necessity in the production of good potatoes, that the supply of water be withheld in time to stop the growth and allow the tuber to ripen before the tops are entirely killed by frost.

I have kept no accurate account of the extra expense of irrigation; but when I consider that the soil is made to yield its utmost capacity with uniformity, and that the hands irrigating can always do extra work enough to pay expenses, I am decidedly in favor of systematic irrigation, and never shall own a farm without facilities for irrigating a considerable part thereof. To the advantages already enumerated, may be added this, that the soil is continually enriched by the mineral, animal and vegetable matter contained in the water; while the extra crop produced always enables the true farmer to return to the soil greater quantities of fertilizing manures.

Reservoirs and ditches once well made, last for ages; the water may, in many cases, be used for threshing, grinding, churning, etc., etc., and afterwards applied to the land, and in many places the reservoirs may be made both ornamental and useful, by raising fish in them, and that too with little or no additional expense.

There are here few farms without the means of irrigating at least a part. All our low lands are capable of being arranged for and supplied with water. Suppose every man who owns a living spring, rivulet, creek, or has land on the river bottom, to be in a state of readiness to use the water judiciously, what would be the result? 1st, scarcity would be an impossibility. In a season when rains seldom fall, crops must be short; and a farmer can make more on ten acres well tilled than his whole farm would pay in ordinary seasons, besides the security of *seed time* and *harvest, bread* and *meat*. 2d, The moral effect on himself, family, and the world at large will more than compensate for the extra expense. 3d, The expense of culture is less, proportionately. 4th, Less land will produce the ordinary amount; the balance can rest. 5th, Smaller farms, better culture, and greater certainty, will open the way for supporting a denser population, both of producers and consumers.

Let any man who doubts these statements take one, two, or three acres, make the experiment, and report the result for the benefit of his fellows. Too little attention is given to this subject; frequently whole districts are in a condition of starvation, as was the case in Kansas, solely because they are not prepared to use the means nature furnishes bountifully. From my personal knowledge of the Kansas River and its tributaries, I do not hesitate to affirm that in the valleys of those streams four times the amount necessary to support the entire population of the State could have been produced. And yet Kansas begged for seed and bread. Except on rivers the water is easily diverted from its accustomed channel, and directed where needed. In many places a few feet of spading, a small dam, and the plow does the balance as fast as a team can walk. The water itself furnishes power to lift water for irrigation—wind mills may be made to do the work, and rather than the population should starve or beg, horses and cattle could be used to advantage where the water required lifting only a few feet. But usually the fall in the stream furnishes all the conditions necessary. With the great amount of fertile soil in our valleys, how easy it would be to secure ourselves against want and dependence.

The fact is, by concentrating labor on the valleys in time of drouth, pinching scarcity need never be felt. This subject appeals not alone to the selfish propensities of humanity, but will be appreciated by the true philanthropist—one who comprehends the moral effect of plenty, both on the buyer and the seller, and the absolute necessity of a regular supply of food and raiment to human progress.

Raising Turnips.

It is altogether too late in the day to question the utility of the turnip crop. The raising of those varieties wanted for table use, is no unimportant matter. We could almost as soon think of Thanksgiving dinner without the turkey, as without the savory dish of early white Dutch turnips. Carefully stored in the root cellar, or put down in boxes of sand in the common house cellar, they will keep fresh and juicy all winter. For spring use, commend us to the purple-topped Swede, or rutabaga. We do not recommend any of these as being particularly easy of digestion; but, eaten in moderation, they serve as a good relish and accompaniment to other food. For stock feeding this root is of great value. For producing milk, for fattening, or for keeping up the general health of cattle, swine and sheep, through the cold season, their importance is not easily over-estimated. It is a great economy to use them especially in seasons where there is a scarcity of other fodder. A leading English agriculturist once said that the failure of the turnip crop there would be a greater blow to the nation's prosperity than the failure of the Bank of England. Nothing like this would be true for our own country, perhaps; yet it is a fact that the turnip crop is one of great importance.

The first of this month is in time for sowing the Rutabagas and Swedes, but a longer season is desirable if wanted for stock feeding. With other varieties we may follow the old adage,

"Twenty-fifth of July, sow turnips, wet or dry."

But this, like other adages, must be taken with qualification. Sow the seed in July whenever the ground is moist enough to give the seeds a quick start. The land should be rich, clear of weeds, light and warm: a black muck, rather sandy, is best. If a piece of newly cleared land can be found, turn it over and sow on that: the crop will be quite sure. The seed germinates quickly, and insects are less troublesome than on old land. Next best is a sward ground. The soil having been worked fine, sow in drills half an inch deep, fifteen inches to two feet apart, and at the rate of one and a half pounds to the acre. Abercrombie says: "half an ounce to every hundred square feet." The seeds will germinate in from thirty six to forty eight hours.

As soon as the plants are up, look out for weeds and insects. Work the drills with cultivator or wheel-hoe, and the rapid growth will reward all the labor. When the plants have made rough leaves an inch broad, hoe them and thin out to six or eight inches apart. Continue the thinnings afterwards, until the roots finally stand eight or ten inches apart. If a little plaster is sown broadcast over the plants when well established, it will give them increased vigor.

To destroy that great pest, the fly, some use soot, ashes, or air-slacked lime, strewing it on the leaves when wet; but warm, moist weather will soon carry the plants beyond the reach of flies. Still, if the insects persist, and the young plants are eaten up, dig up the ground and sow again.

An Illinois farmer, speaking of the expense of living at the West says: "It will vary with the size of the family, and *their propensity to gratify pride,—an expensive article in a new country.*

To Improve Sandy Soils.

The defect in such soils is chiefly of this sort: They are mechanically defective, being so light and porous that they can not retain moisture, or manure, if applied. Besides, they are generally wanting in various important elements of plant growth. Therefore, to improve them, we must endeavor to supply these radical defects. The first point can be gained by spreading a coat of clay over the surface and dragging it in. This will improve its texture, and will also impart fertility. Adhesiveness and strength having been gained, manure from the barn-yard may be applied as fast as it can be procured. Another method is to dress such lands with rough composts. Prepare the heaps at leisure, in the barn-yard. The ingredients may be such as these: ten loads of stable dung mixed with five loads of clayey soil, twenty bushels of ashes, and the same amount of lime. After these articles have been well incorporated, let the mass lie for a month or two; then it will be ready for use. Such a compost, it is easy to see, will be more enduring, and better in all respects, than the same bulk of barn-yard manure. It will improve the quality of the land permanently, and will enrich it with a fertility which will be very lasting. On every farm of the kind here supposed, there should be one or more compost heaps of some sort *constantly* building.

A Ring for the Bull's Nose.

A young bull is sometimes very handsome, and a very pleasant thing to pet and fondle. Sometimes children cosset and handle him in the pasture and yard for a year or two, when suddenly, the animal turns upon them, first in play, and then in fury, and they hardly escape with their lives. Not a year now passes, in which we do not hear of some farmer who, being in the field among his cattle, is set upon by his fine bull, tossed in the air, gored to death, or in some way wounded more or less severely, and perhaps maimed for life.

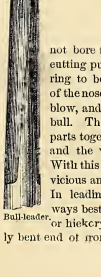
The only safe way to handle these creatures, is to put a stout ring in the nose of each. When this is once done, it is for life. The operation is not so cruel as some imagine, certainly no more so than the barbaric practice of boring our children's ears, for hanging rings in them. (Why

Full-ring.

not bore their noses, as well?) Get a cutting punch a little larger than the ring to be inserted, and the cartilage of the nose can be perforated at a single blow, and that with little pain to the bull. Then put in the ring, screw the parts together, (as shown in the cut,) and the wound will soon heal over. With this simple contrivance, the most vicious animal can be safely managed. In leading a fractious bull, it is always best to have a stout, six-foot, ash or hickory staff upon which is a spirally bent end of iron, called a "twist hook," or to which, by a few links of a chain, a "snap-hook" is firmly attached. A bull will never tear his ring out while being held or led by hand. Tied to a post, or behind a cart, sometimes by a sudden start he will tear out the ring before he realizes what he is about. In such a case, if seized at once by the nose, he may be held. But no animal should ever be fastened in this way. A rope around the horns is the proper fastening, and if by any means this gets loose or breaks, then the ring will generally hold. The ring affords an easy means of getting hold of a fractious bull in a pen, box stall, or stable, by means of a "bull-leader" as described and shown in the cut. What farmer or patriot will not say: Anything, oh! anything, to prevent a Bull-run, whether on the farm or the battle field!

Leading-clasp.

The "leading-clasps" are of various forms, in general, however, like the one shown in the cut annexed, and differing in the manner in which they open and shut, and are held shut. The ball-tipped ends separated, are placed within the nostrils, and are then closed together, space being left for the cartilage of the nose between them. They can not be unclasped by any action of the bull, nor torn out without subjecting him to as great pain as if a ring were torn out. These clasps are very convenient for leading any neat animal which is not perfectly docile. When there is any doubt who is master, a ring or leading-clasp affords to the mind of the animal a very ready solution of the question. For bulls, however, the permanent nose-jewel above described is decidedly preferable.



Bull-leader.

Notes on the May Agriculturist.

BY A WESTERN FARMER.

Central Park Conservatory, p. 133.—One of the best things possible—and the Parsons are the very men to manage such an enterprise honorably and successfully. With a few other attachments, such as an arboretum, a herbarium, an aquarium, and a zoological garden, as we hope some day to see, the New-York Central Park will become the most attractive spot in North America.

Six Good Pears, p. 133.—I can name six *better* ones: to wit.: Bloodgood, or Osband's Summer, of which you may take your choice, or have both, for early; Bartlett, White, and Gray Doyenne, or Virgalieu—if you can grow them without cracking; Brown Beurre, Seckel, Winter Nellis, Glout Morceau. These will all grow on the quince for dwarfs, as well as the "six good ones," if double worked—if folks will insist on having dwarfs—and they flourish finely on standards. Why our nurserymen will continue to laud up such coarse and flavorless things as the Duchesse, and Vicar, I can't imagine, only that they are showy, and succeed better on the quince than almost any thing else. As table fruit they are worthless, and for cooking, decidedly inferior to a score of others. [But the fruit *sells*, sometimes at a dollar a pear.—Ed.]

An Agricultural Bureau—Who shall be at the Head of it, p. 136.—Nobody—unless he can be better than any thing who has yet figured in that department. Genl. Banks may be a good man for aught I know, provided he'll throw aside his politics—when he gets there. Such an office needs a common-sense man, whose tastes and proclivities are decidedly agricultural, and has gumption enough to discriminate between the pretensions of quacks, and honest, well-tried experience. The *trade* of administering such a Department of the Government, has yet to be learned by whoever may be the incumbent, and the office should not be one of rotation, or removable without cause.

Dead Animals for Manure, p. 140.—True, every word of it; and if men would only believe such things, thousands of dead carcasses which every year pollute the air with their putridity would be turned into the most fertilizing materials.

Tim Bunker on the Horn-Ail, p. 140.—"Tim" is a great man in his line, and utters a deal of homely truth in his neighborhood observations. But, somehow or other, Tim's grammar and style have wonderfully improved of late. I think he must have been taking evening lessons in spelling and punctuation of his district schoolmaster.

The best Team on the Farm, p. 140.—You can't make a northern farmer drive a mule team, unless he goes off South and couples "niggers" with his mules, and then he becomes a worse "driver" of both than him "to the manor born." Off South, the mule is decidedly the best and most profitable team. I have seen scores of arguments, *pro* and *con*, as to the best and most profitable teams for northern farmers to use, and the advocate of each was right or wrong—according to circumstances. On *good* lands, and free soils, horses are best. On poor lands, and over rough soils, oxen are preferred. Horses are indispensable for marketing purposes, where a man's time is worth any thing. In my own practice I have always used both, finding each preferable for certain kinds of labor. Every man must judge for himself, by his own experience, which of either, or both, he is to prefer. The whole article is capital.

A few Hints about Plowing, p. 141.—A good article. But after all, the farmer must *know* his soil, to understand the best manner of plowing it. Heavy clays require a different mode of plowing from friable loams, or gravels; and the natural, or acquired fertility of the soil has much to do with it also. I know lands where you may bury the plow to the beam, and all the better for it, while in others six inches is abundance. One may theorize until he is gray, and never draw a right conclusion. Experience, *with* theory, is the sure way to test all things.

Sorghum Syrup for North, p. 143.—I doubt whether this can be made a paying crop north of 41°. The cane requires a long summer and a hot sun to develop its saccharine to the utmost. We have millions of acres of the best sorghum lands at about 41°, and one or two degrees south of it; and while they are *sure* for its growth, it is hardly worth while to run much risk for a *chance* crop north of it. Better work our lands with something that is *certain* in production, and exchange that, or the avails of it, for the uncertain ones that we need.

Timothy Mowing-Lands, p. 143.—Partly true, and partly not. Timothy is *not* "a poor pasture grass," and "every body" *don't* "know it." I assert it to be among the *very best* of pasture grasses, and if anybody don't believe it, let him turn his stock into a field of mixed grasses, and wherever the timothy predominates, see how eagerly they will crop it in preference to the others. Timothy can be fed too close, I acknowledge, and it should *never* be fed in the Spring of the year. Nor should *heavy* stock ever be turned upon it when the ground is soft, as late in the Fall or Winter, for their heavy tread will *poteh* and destroy it. I have had timothy, with other grasses, in pasture for more than twenty years, where it holds its own with them, and has been pastured with every thing that eats grass on the farm. *My* rule is always to sow a good share of timothy on both pasture and mowing lands when I lay them down with red clover. The blue grass and white clover will come in of themselves where the land is natural to them; and so will red-top, on moist grounds—one of the best of our grasses for either pasture, or hay.

The Apple Orchard, p. 145.—A good article, and to appearance, by a practiced hand. As to varieties for cultivation, no positive rules, irrespective of soil,

climate, and locality of the orchardist, will apply. The demand of the market, and the varieties most favorable to the soil and climate, must measurably govern. A good apple in one place may be worthless in another, and no man's *ipse dixit* of a "best selection" is worth a copper for *all* localities. I need not go into particulars to prove the truth of this; but if any one doubts it, let him try, and an experience of a dozen years will show him that he has fooled away a good share of both his time and money. I am this Spring grafting over many well grown trees with sure and productive kinds, in place of the *fancy* things that I was thoughtless enough to put in because some partial ignoramus made me believe they would do well with me, because they were favorite kinds three hundred miles away. The table of "best apples for different localities" is useful, and no doubt reliable, as founded on the experience of those who "voted" them. [These remarks may as well be applied to pears.]

Crinoline Flower Pots! p. 149.—Well, what next? I thought the "wimmen" had all the *crinoline* to themselves; and if the flower pots are coming in for a share of the article, where will it end?

"*Hulled Corn.*"—Yes; it used to be good in my boyhood, when potatoes-and-milk, bean-porridge, johnnycake and brown bread were every-day edibles on the table. But since wheat flour and rice have got to be plenty and cheap, our housekeepers have found out that it is "too much trouble" to make the "hulled corn." Yet, it is good, I admit—if you can get the "ley" taste all out of it. But, as things go, I never expect to eat a dish of hulled corn again; and I don't know that I shall cry about it, either. I don't believe even "Aunt Mary" cares much about sweltering over a pot, with her ash-barrel and ley kettle lumbering up her washroom, for the sake of getting up a dish which the majority of her "young folks" will be inclined to turn up their noses at when they find out that "poor folks" lived on it fifty or a hundred years ago.

Buckwheat—Its Place in our Agriculture.

Buckwheat fills a place in our list of crops that no other plant can. It has the name of the lazy man's crop, from the little preparation the land needs for its cultivation, and the ease with which it may be grown. This is perhaps the chief objection to the crop; it favors slack husbandry, and yields a remunerative crop so long that some lands have been entirely run out by cropping with it. You can skin land more effectually with buckwheat than with any other crop. On this account, and some others, the crop is not a favorite one with many of our best farmers. It is said to poison the land for corn, and the cases are pretty numerous where corn following buckwheat has failed. The succession is certainly not to be recommended. The seed also remains in the land for a year or two after it is sown, and makes its appearance among subsequent crops more than any other grain. To the farmer who loves clean seed, this is a serious objection. It can be remedied by following it with a hoed crop, or by stocking down to grass.

Buckwheat may be sown where other crops have failed, or could not be planted on account of the wetness of the land, or lateness in its preparation. It is usually sown from the middle of June to the middle of July, the latter month generally being preferred, where the object is to get grain. If sown too early, there is danger that the grain will not fill out well in the hot weather of August. If too late it is liable to be cut off by the early frosts.

The yield is generous, even on soils where other grains would not pay. But we doubt the policy of growing this or any other grain without manure. There is no crop, not even turnips, to which Peruvian guano is so well adapted, and on which it shows such marked results. We have seen a heavy crop grown on exhausted land with only a bag to the acre. From ten to fifteen bushels to the acre is a common yield on rather poor, though not exhausted, land. With the guano the yield is frequently doubled. Where this is the case it makes a very handsome profit on the manure. But it is only in special emergencies and where there is a deficiency of farmyard manure, that guano is to be recommended. The like benefit will not accrue from its use the second year upon the same land.

It is an excellent cleansing crop, where land has become foul with charlock, wild worm-wood, Canada thistles, and other weeds. It grows so rapidly that it gets the start of all other plants, and keeps it. It completely shades the ground. It is for this reason that it is so often sown upon swales, and brush pasture recently cleared, where there are many coarse clods. The roots and sods are kept moist by the shade, and decomposition goes on rapidly. It is well adapted to newly cleared lands full of vegetable matter.

Buckwheat stands high among the plants to be turned in for manure. It matures so rapidly that two crops can be turned under in a season, or a crop of clover, and a crop of buckwheat following. It does admirably well to precede a crop of rye. It may be sown any time before the first of this month, turned in the last of August, and the rye sown soon after. It is claimed by those who have tried the experiment for several years, that a crop of rye may be taken from the land every year by this process, and the soil all the while improve.

Two to four pecks are ample seed for an acre, the less quantity being used on rich land. For feeding, it is nearly equal to Indian corn. John Johnston, who is authority in fattening cattle, prefers a feed of one half buckwheat, to one wholly of corn, at the same price. It is used extensively for fattening poultry and swine, both whole, and ground with other grains. A very common provender in New-England is oats, corn and buckwheat mixed in equal parts and ground. This is mixed with potatoes for swine, and with hay for working horses.

Tobacco Cultivation—No. V.

The tobacco fields have, by the first of July, escaped the dangers of infancy, and though many a plant has become a "cast away," or fallen in the field of conflict with worms, sun, and storms, the thinned ranks have been filled, and raw recruits are making up for lost time. Hot-days with occasional showers, cause tobacco to "grow like a weed." There is little danger of dry weather injuring the crop, if the ground has been well prepared, and the surface is kept stirred so long as it is possible without tearing the leaves. After this, the thick leaves so shade the ground that it is kept moist.

The hawk-moths or sphinges begin to fly in July, or perhaps earlier, but at this time are first particularly noticeable. The *Sphinx Carolina*, (the hornblower moth,) is the parent of the tobacco worm. It is a very large moth which flies at dusk, seeking its food, which is honey, in various flowers open at night—potato blossoms, wild evening primrose (*Œnothera*), foxgloves, and other garden flowers, but particularly in the large funnel-shaped blossoms of the stramonium or Jamestown-weed, (*Datura stramonium*). This moth is as large and has somewhat the flight of a small bird, hovering about here and there—quick in its motions, not very shy, and resting before the flowers into which it thrusts its long thread-like proboscis, which in its flight is curled up like a watch spring. The moth is of an ash-gray color; fore-wings with blackish, wavy lines; hind-wings, whitish in the middle, with four black bands, the two central ones narrow and jagged; fringes spotted with white; five orange-colored spots on each side the abdomen; the proboscis exceedingly long. The spread of the wings is often 5 inches. The more there are killed of these moths the fewer will be the worms in the field. The eggs are deposited near the edge of the leaf on the underside, and hatch in about a week. The apple-green larvæ feed very quietly on the under surface for some time, but finally become quite active and ravenous.

Poisoning the Hornblowers.—The moth may be easily killed by watching near some of the flowers mentioned and striking them down. If the common fly poison of the shops, called "*cobalt*," (but really *black arsenic*, though the majority of druggists and other dealers do not know it,) be very finely pulverized, and two ounces be put into a half pint phial, and filled up with equal parts honey and water, after standing a few hours it makes a seductive and fatal beverage to the hornblowers. The best way to administer it is, by means of a little syringe, to drop half a dozen drops in each available flower of the stramonium situated near the fields, and in case these are not abundant, in the blossoms of the other flowers mentioned. It is a good plan also to pick some stramonium flowers and phlox them, filled with the poisoned nectar, in the tobacco field at the time the moths are laying their eggs. In fact we think for bee-keepers the poisoning should be effected by putting the bait altogether in plucked flowers, which would wither before the bees fly much. Of course since the moths fly only in the dusk of the evening, the poisoning must be done at that time. There are several cases reported of this poisoning being very successful, and we have therefore given the method in detail.

A flock of young turkeys will make way with an immense number of worms, and without doing any special damage to the leaves, particularly if they visit the field in the early morning when most of the worms are under the lower leaves. It is not a very agreeable duty of the field hands to find and crush between the fingers as many of these worms as possible; but to this end the field must often be thoroughly searched through, investigation being made at every hoeing, and oftener, if necessary. When the plants grow too large to be hoed, and the large leaves form in the perfection of which the great value of the crop consists, vigilance must increase. Instead of crushing the worms, when they are abundant we advise *bagging* them, (each man having a pocket or bag at his side). It is less disgusting, and a supply of chicken-meat is thus obtained.

It is in August that the greatest labor and care is necessary to prevent injury from the worms, and it is seldom necessary to "top" the plants before the middle of the same month. In some very forward fields, however, the plants will be ready for topping by August 1st. This is done by breaking off the tops about 2 or 2½ feet high, according to the vigor of the plant. The object of this is to throw into the leaves that force which would otherwise be expended in producing seed. Branches will start from the axils of the leaves, and must be watched and removed continually. The plant should be topped before these "suckers" start, and higher or lower, according to the season, and the time left for maturing the leaves. This will form the subject of our next article on tobacco culture.

The Articles on Winter Wheat.

The committee to whom was referred some 15 essays or articles on the culture of Winter wheat, return two articles, and recommend a division of the premium. One is the soundest and best, but very brief; the other more in detail, but rather old fogyish, and both describe the practice rather of Eastern, than of Western or prairie farmers. The general principles of wheat culture depend upon the nature of the grain, and are invariable. The details of culture vary with the soil and the climate, the danger from insects, the demands of the market, the expense of labor, etc. We are disappointed in not having received, in response to the liberal premiums offered, essays involving more thought and labor, and it may pertinently be asked: "If neither of the articles are worthy of the prize, how can you justify a division of it?" We do not like to go behind the decision of a committee, and besides, there are very many valuable and practical hints and directions in the articles, taken together.

The necessity or great desirableness of underdraining is not sufficiently brought out. The numerous and explicit articles previously published in the *Agriculturist* on this subject, find in this crop important application. The recommendation to provide surface drains, in the second article, was accompanied by a long account of the surface drainage of wheat fields, which we have thought it best to omit. Thorough underdraining with tiles, four feet deep and 33½ rods apart, is doubtless the best preliminary preparation a wheat field can have, unless it be drained by nature, and gravel beds, to such an extent as to render further drainage unneeded. Stone-drains, brush-drains, wood-drains, are each advisable under certain circumstances; and in the stoneless soils of the West, mole-draining by simply passing a "mole" or "mole plow" through the ground at a depth of 20 to 30 inches, is found of great service, affording a means of draining the prairies at a cost of 8 to 10 cents per rod, in a manner which will last for several years.

There can be no doubt that culling heads for one's own seed is exceedingly advantageous. This is done by letting the best part of the field stand to get very nearly or quite ripe, and then going into it and plucking the largest and longest heads, separating the shrunken grain after it is thrashed or rubbed out. It will pay, and where wheat is drilled may very easily be done. This process should be followed up for several years in order to secure the best results—planting culled seed grown from culled seed. The wheat is an improvable plant, perhaps the most so of all our cereals. In this way, new varieties may be originated, with plumper grain, giving a larger yield to the acre, and more flour to the bushel. This process pays well in England, in the higher price such improved wheat brings for seed—frequently three times the price of miller's wheat.

In regard to drilling, our farmers shrink from it on account of the cost of the drill. Necessity or supposed necessity influences a feeling of preference; and so indiscriminate broadcast sowing finds advocates. There is no doubt in the minds of most who can afford to use one, that the grain drill very soon pays for itself. The principles upon which it operates apply to all soils, and the results of its use are very uniformly advantageous.

The use of the reaping machine is gaining advocates very rapidly, as machines come to be more conveniently managed. It is true that tasty cradlers will lay down an acre of wheat in a very short time, with less waste from shelling if the grain be too ripe—and on small farms, or in small fields, with less expense; but when the fields are extensive, the grain in a proper state and the reaper a good one, the comparison of the relative convenience and expense will be in favor of the machine. The same is true in regard to thrashing;—either muskilled hands, a poor machine, or a small quantity of grain to be thrashed, will be a reason why thrashing by the flail would be preferred. Grain caps were commented upon in the June *Agriculturist;* we believe in them, and though not so much needed for grain as for hay, they will turn rain perfectly, and may save the entire crop from sprouting.

The great want, perhaps, in wheat-growing, especially in the older States, is the conviction that the thing can be made to pay. As soon as our farmers can see this, they will learn how to do it. This conviction is growing, we have no doubt, in many of the districts where wheat had been abandoned for a time. It is no wonder that the crop failed so generally in New-England, for it certainly requires more skill, if not more manure, than most other crops. It went out more from lack of manure, than from the multitude of its enemies, though we would by no means underrate the latter. A farmer sowed without manure upon poor land, and got a poor crop, as he deserved to. The trouble was in the man, not in the plant. A few farmers who were willing to do justice to the plant, have never ceased to get a paying crop. Gov. Colby, of New-Hampshire, boasts that neither he nor his fathers ever bought a barrel of flour.

[PRIZE ARTICLE.]

Cultivation of Winter Wheat.

BY J. HOLMES, CHITTENDEN CO., VT.

Wheat, one of the greatest staples of the country, if rightly managed may be made one of the most profitable of our cereals, upon almost any soil. Twenty years' experience has demonstrated to me that we hardly need fail of success, if the following mode of proceeding be strictly followed.

SELECTION OF SEED.

Select none but the best seed of bearded wheat. The White chaff is preferable, it being worth some ten cents more per bushel in Eastern markets. Prepare a strong brine—do not depend upon old beef or pork brine, and wash as long as any filth or immature grain rises to the surface. By this process we shall expel from two to three quarts of foul seed and shrunken grain per bushel, from what would be called an "extra" article. Seed prepared in this manner will send up none but the most hardy and vigorous plants, consequently will be less liable to winter-kill; and as like produces like, we may look for an article in the increase equal if not superior to that which was sown. Add three quarts of dry, fresh-slacked lime to every bushel of wheat; mix up thoroughly two days, or two weeks, previous to sowing. *This is important—neglect the lime* and nine times out of ten you will have more or less smut, which will depreciate the value of the wheat.

PREPARATION OF GROUND, SEEDING, ETC.

The ground, if rich and strong enough, may be sown after peas, otherwise, after summer fallow. In either case, manure on the surface, and plow or drag in with the wheat. I prefer to use about fifteen loads to the acre thus prepared; then, after sowing thinly, to plow it in. The seed, by coming in immediate contact with the manure, receives a thrifty and vigorous start, which it otherwise would not attain. This I think is highly important to insure success. I have never used the drill, but in its stead Ide's cultivator which answers a good purpose. If you harrow in the seed, in no case roll afterwards, as the inequalities of the surface will prevent the snow from blowing off, and the plants will be less liable to be affected by frost. But if covered with a drill or cultivator this precaution is unnecessary, the seed being so much deeper, and the roots less exposed. When the ground is settled in Spring, go over with a heavy roller; it covers many exposed roots and often adds five to seven bushels per acre.

Have the ground well pulverised previous to sowing; it is useless to sow on lumpy and badly prepared soil. In case there is no manure to be had, cover the surface immediately after sowing and before the wheat starts, with a light layer of straw; the wheat in a short time will come through, and prevent it from blowing off. The straw will act as a mulch, and the ground being shaded will retain the moisture; and if the soil is not very poor you may expect a good paying crop. Two and-a-half bushels salt per acre tends to prevent rust, makes the straw strong and bright, and gives the young wheat a dark color. If any one doubts the truth of this statement, I hope he will make the experiment, and my word for it, he will at once adopt the practice. I know of no better mode to prevent the ravages of the midge than early sowing, and even this sometimes fails. The last week in August, or the first in September, I would prefer, but this depends upon circumstances; if the weather is dry and hot, I would rather wait until October. Some years since I made an experiment to test early and late sowing. One piece was sowed the last week in August; one the last week in September, and one the middle of October, on the same kind of soil and treated in every respect alike. There was no difference in the time of ripening or in the quality of the grain, but the earliest sowed produced the longest heads, consequently yielded more per acre.

I do not sow plaster on wheat, as it tends to rust, and increases the bulk of straw but not of grain.

HARVESTING.

Cut wheat as soon as the straw presents a golden appearance below the head to the first joint. The grain will be somewhat soft, but there need be no fear of shrinkage; it will produce more and better flour per bushel than if let stand until it becomes thoroughly dry. Bind in small sheaves; put them in a stook capped with two sheaves securely bound on. Put up in this manner wheat will stand through a long spell of wet weather without any fear of growing. If possible thrash with a machine as it is drawn to the barn; it will save once handling and it may then at once be scoured from all kinds of vermin and will be free from filth, which will enhance its value. Of course if the above directions are followed, your wheat will be of such a superior quality that it will be marketed at your own door for seed, which will save the expense of transportation, and will command fifty cents more per bushel than an ordinary article, and in proof of the above theory I will give you the result of two fields treated as I have prescribed. From one acre and four rods, forty three and one half bushels, sold for seed at two dollars per bushel. On the other field I sowed fourteen and one half bushels, and harvested three hundred and fifteen bushels.

[PRIZE ARTICLE.]

Cultivation of Winter Wheat.

BY JOHN S. GESNER, CANADA WEST.

The writer's experience in the cultivation of winter wheat extends over sixteen years upon loamy clay, and four years upon sandy land. I shall give it just as I would *talk* it.

DRAINAGE.

It is absolutely necessary to ensure a good crop that the land be thoroughly drained—underdraining, if done properly, is without doubt the best; but open or surface draining is the most common, and is that upon which my experience has been formed. I think that a field can not be too well drained, not only after it is sown, but previously—and that extra labor in clearing out and keeping clear every ditch, and digging large outlets, is amply rewarded by the extra yield.

SOIL.

A loamy clay I consider the best for wheat. I would prefer four or five inches of loam, with clay subsoil. This I always summer fallow—plow in May, deep as I can, putting on two teams if one will not turn it deep enough, harrow well, cross plow in June, in July cultivate with a two horse *cultivator* or *scrabbler*. The latter part of August manure well, and immediately plow again in 11-foot ridges, cutting narrow, deep furrows.

If the soil be light and sandy I would summer-fallow only in case of a new or weedy piece of land, which I intended to seed down. My way is to turn under a good crop of clover about the middle of June. The clover may be fed off until nearly the first of June, at which time sow about 2 bushels of gypsum (plaster) per acre. This will give the clover a good growth, and will be of service to the coming wheat. Plow in the clover deeply; a piece of chain about 3 feet long fastened to the coulter of

the plow so as to drag in the furrow, will be found of service in helping to turn under the clover. Manure well, and use the two-horse cultivator thoroughly about the last of August, and you have a good seed-bed.

VARIETIES.

My favorite kind of wheat is a bearded variety, known as the "Kentucky White," or "Hutchinson's." I know that bald varieties, such as "Blue Stem," "Soule's" and "White Flint" will, if not damaged by insects or rust, yield the most per acre, but owing to the midge (see *Insects*), I much prefer bearded varieties. Take the earliest, best and cleanest wheat you can get for seed. Depend upon it, dirty seed will bring a dirty crop—I don't believe that wheat will turn to chess.

If any thing should prevent early sowing, I would then sow "Mediterranean," because it will mature here quicker than any other variety, which is quite an item in late sowing. Treatment of seed is the same upon either clayey or sandy soils.

TIME OF SOWING.

The last week in August and first week in September I have found the best time for sowing. In this section sowing later is useless, unless you sow "Mediterranean." Should the weather be very growing, and the wheat getting too much top to stand the deep snows, turn on your stock and feed it off. There is no danger in pasturing wheat moderately, if your land is well drained. In fact, I think it does it good by enriching the soil. The plants should not be nipped close to the ground—but moderately pastured, so as to reduce the tops of the plants to enable them to winter safely.

MODE OF SOWING.

I sow "broadcast," and use a half bushel measure to sow out of. Take a strap, pass it through one of the handles of the measure, (or a hole made for the purpose), and unite the two ends so that when it goes over the neck the measure will be convenient to dip the right hand into. You can thus always know exactly how much seed you are using per acre. On a ridge 11 feet wide, I go and return upon the same ridge. Place the seed in bags in the most convenient places upon the field. A little practice will enable any person to sow quickly and evenly.

QUALITY OF SEED, ETC.

I have found 1½ bushels per acre enough, when sown early; if sown late (Mediterranean) I would sow two bushels per acre. I have tried brining the seed, liming it, and various highly recommended decoctions, but never realized any benefit from their use. Sow good clean seed, and it need only to be well covered with good earth. Dibbling and drilling in the seed does very well when only a small quantity is sown, and you wish to obtain as much from the amount of seed sown as possible; but when much ground is sown I decidedly prefer broadcast sowing, notwithstanding a larger amount of seed is used. Drilling in wheat, and then hoeing it afterwards, does exceedingly well in theory, but does not succeed so well in practice; every thing must be done nearly right to enable you to hoe without hoeing up your wheat. In fact, when the wheat crop is the main crop of the farm, and much has to depend upon *hired* labor, the simpler and the stronger the working implements are, the better. We raise wheat *to pay*, and if we do not raise as much per acre, if the *profit* is more, the better for us.

HARROWING AND ROLLING.

After sowing, harrow thoroughly—you can not harrow too much,—and put on a good heavy roller. The land is then ready for furrowing for surface draining. I have found it a good plan to roll wheat also in the Spring, as soon as the frost is out of the ground—particularly upon land that the frost has hoven much. It presses many roots into the ground, which would otherwise be killed by the sun. I have also found it a good plan upon a piece of wheat which has suffered much from the action of Jack Frost, but has clumps of wheat still left, to run over it twice in the Spring with a light harrow, and then roll with a heavy roller. It divides the remaining roots, and although *hard looking* at first, the growing crop will soon astonish you with a change for the better. I do not believe in sowing "plaster" in the Spring upon wheat. Plaster should be used, if at all, upon the crop which precedes the wheat. If I thought my land was not rich enough in the Spring, I would top-dress with either stable manure or guano; but I prefer to have the land rich enough before the wheat is sown.

HARVESTING.

I always let wheat intended for seed get *dead ripe*; the rest I hold commence cutting before the grain is quite hard. If too green, it makes dirty and heavy work; but when you have a good deal to cut, you had better cut some of it a little green, than lose by its getting too ripe. Bearded varieties always shell very much when dead ripe. If care is used, however, in handling, not so much is lost by shelling as one would at first suppose. When wheat ripens from the *head downwards* you can cut very green without danger of shrinking. I do not, like some wheat-growers, say that wheat is better and plumper cut green, for it is my belief that every crop should come to maturity before harvesting.

Never bind too large. Have the sheaves of moderate and uniform size. Rake thoroughly, as it is very easy to leave enough to pay for cutting and binding upon the ground. In *setting up* or *shocking* I always set 10 or 12 sheaves together in a row, 5 or 6 on each side; I never cap my shocks. If carefully set up, they will stand; and in case of rain, will dry quicker without caps. We often have what is here called *catching* weather—and often grain is damaged. It is therefore the safest to house or stack as soon as the grain is fit.

THRASHING, CLEANING AND MARKETING.

Now that horse power thrashing machines are so easily obtained, the old-fashioned way of thrashing with the "flail," or with horses upon a large floor, is mostly done away with, and the new-fashioned machines are a great advantage to the farmer. I think, however, that wheat for seed is better if thrashed with the flail, and would always prefer it to that thrashed with a cylinder at great speed, which I believe injures many of the grains; perhaps not enough to prevent their growing, but enough to prevent the plant from being as hardy as though the grain were perfectly sound. It is a farmer's duty to clean not only his wheat for seed and bread, but every bushel he sells, thoroughly. On account of the carelessness of too many farmers in this respect, our market for wheat is injured very much. In marketing, as a general rule for at least this section of the country, it is better to sell in the Fall; you save all that would be lost during the Winter by mice, rats, etc., and have the use of the proceeds sooner. Much, however, depends upon circumstances, and a man must use his judgment in the matter; for it often happens that wheat is low in the Fall, with every prospect of being much higher in the Spring. In such case hold on to the grain; but if a good price is offered in the Fall, sell it.

INJURIOUS INSECTS, RUST, ETC.

Under this head I shall be very brief, for learned men have written much upon the subject, which every farmer ought to read. To those who have not, I would say, by all means read the works of Dr. Fitch, of New-York, upon the insects injurious to vegetation. The wheat fly or "midge" does a great deal of damage to late-sown wheat, and is much worse upon bald, than upon bearded varieties. For this reason I always sow bearded varieties. In my opinion the only remedy for the midge is—*to drain well—manure well*, sow early, and sow an early kind of hardy, bearded wheat. In every case where I have done this, I have escaped the ravages of the "midge,"—while my neighbors who have done otherwise have suffered very much. I examined this season a field sown very late with "Mediterranean," the seed of which was mixed with "old redchaff" (bald). Every head of the bald was completely destroyed by the midge, while the bearded was but little injured; and I firmly believe that in sowing late, mixing in a portion of bald wheat seed will preserve the bearded variety from the "midge." If the wolf (or grain weevil) attacks the wheat, (which it seldom does here, to any extent,) I would thrash out as soon as possible. If any insects survive the thrashing cylinder, I would spread out the grain to the sun, when they will all vanish.

The wire worm is the curse of wheat-growing here. As yet I think no certain remedy for this pest has been found. The best remedy I have tried is frequent plowing and harrowing, both in Spring and Fall, disturbing them as much as possible, never allowing a field to remain too long in sod. Old pastures or meadows are complete nurseries for wire worms. But above all things, cultivate an intimacy with birds. Not only wire worms and "midge," but all kinds of insects injurious to the farmer, are destroyed in countless numbers by the birds; and until we encourage in every practicable way the presence of birds, we may expect to suffer.

I believe rust, like mildew, is caused by exhalations which arise from the ground, with damp fogs, and stimulate the growth of the plant to such an extent as to cause the rust to appear; and I further believe that thorough draining, good cultivation, with the use of hardy varieties, early sown, are the best preventives. Where lands are rich in ammonia, the straw will be ranker and much later. I should in such cases sow about two bushels of salt per acre just before any danger of rust.

In conclusion I would say that I consider 35 bushels per acre a fair crop. If every thing is right, more per acre will grow; and I have no doubt that the day is not far distant when, wheat-growing having become more of a science, 50 and 60 bushels per acre will be called an average crop. There is one thing I am convinced of, and that is, that in spite of all known injurious insects, wheat can, under proper management, be grown to pay the farmer, and pay well, too. I think the onslaught of the insect tribe upon the wheat will result in good, by bringing about a much better system of farming, which otherwise would never have been attained.

Farming in Iowa.

Raising Wheat and Corn—Shelter for Stock, etc.

To the Editor of the American Agriculturist:

Our best wheat is raised on prairie sod, turned over the previous Summer. The first season of my farming in this section, I sowed 20 acres of Spring wheat on prairie sod, which had been turned over in June of the previous year, and corn dropped in every third furrow. It was harrowed well, at the time of sowing, without cross plowing. I never had a finer piece of wheat. The next Spring I cut the corn stalks from 12 acres, raked them up and burned them. On part of this I sowed wheat without plowing, and part was plowed before sowing. I had much the best wheat on the unplowed portion. We do not use any manure, the soil being sufficiently rich without it, but the time will probably come when manure will be valuable.

Most of our corn is planted on freshly turned prairie sod, dropping from two to four kernels in the crevice between every third furrow, and stamping it in with the heel. We sometimes raise as much as 50 bushels per acre in this way, and the ground is in good condition for Spring wheat.

Much of the stock in this country is still wintered without shelter of any kind. I had a stable for my horses, the first winter of my coming here, but nothing for any other stock. The winter was very severe and I resolved to have a shelter before another winter. Going to the timber, I cut and split strong oak stakes for posts, 8 feet long. These were set in a ditch 2 feet deep, 6 inches apart, and a plank spiked to each stake on top, the earth being filled in firmly about the bottom. Ten feet south of these I set another row of posts, 10 feet apart, and fastened cross timbers on the top of each one, running to the plank on the stakes. Rails were laid on these timbers, and when we thrashed our wheat in Autumn, the straw was used for a roof, topping off with prairie hay. Rude as this is, it forms a good shade in Summer and a shelter in Winter. I have seen unprotected cattle snowed in so that only their heads were visible.

Mahaska Co., Iowa. W. GILMOUR.

THE WATERING PLACE—FROM A PAINTING BY ROSA BONHEUR.
(Engraved for the American Agriculturist.)

Running water is always fashionable with the cows and all grazing animals. See old brindle slaking her thirst, and the calf about to plunge in after her, though he is innocent of all other beverages than his mother's milk, and reckless of the feeble persuasive behind him. The quadruped has manifestly two feet too many for the young biped tugging at the halter. The clear stream is more frequently visited and more enjoyed by the herd, than the most popular watering place by the lords of creation. It is much more essential to their health and thrift.

A very large portion of our Northern States is clearly indicated by nature as a grazing region. We have clear running streams, often fed by cool springs running through green pastures, and the herdsman has hardly to lift his hand to get an income from his fields. He may turn in his cattle in Spring, and take them out in Autumn or before, with a large addition to their weight ready for the butcher. But where fields are near the farm-house, it doubtless pays better to keep a dairy, and to look for the income in the shape of milk, butter, cheese and veal. In this case it is still more important that the water should be clear and pure. Water affects the taste of milk much sooner than the flesh of animals. As a rule, where there are swift running streams nothing more is to be desired for a watering place. There can be no stagnant water, and all impurities are immediately carried off. But it frequently happens in small pastures and upon level land, that there is no brook, while in adjoining fields there are springs upon elevated ground. In such cases it is not a very expensive job to bring in water with a lead pipe, or bored logs, delivering it in a wooden trough. This is much better than to dig a hole in the ground, and puddle the bottom with clay. In such drinking holes the water becomes stagnant, and is made foul with the droppings of cattle. If the trough is raised a little above the ground, they can only get their noses into it, and the flow of water, though small, is as sweet and pure as the largest stream. The next best artificial contrivance is the hydraulic ram, by which we may raise water to any desired hight, and supply reservoirs, of large or small capacity. But to work the ram we must have a running stream of considerable size. This is more frequently used to furnish yards and houses than pastures. If the choice is between a well and one of these puddled holes, by all means dig a well.

The Family Cow.

It is of the pet Alderney or Devon, kept by the villager, that we speak. The prime object is to get milk enough for the family, with a large dash of cream for the berries, and to be frozen in that cheap Summer luxury—ice cream. She is the sole occupant of the stable, daily carded and brushed by Patrick, the admired of the master, and half idolized by the group of children who watch the milking process at morning and evening with longing eyes, and learn that milk does not come from pumps. The owner was not brought up on the farm, does not know good milk, and wants the most of it that can be got out of a single animal at a fair price.

There is not much difficulty in getting a fair supply of milk, say twenty quarts or more daily from a single cow in the month of June, when the pasture is in its glory The quality may be improved somewhat by extra feed, even when the grass is most flush. The difficulty lies in meeting the wants of the family when the feed begins to fall in the latter part of Summer.

A good cow is indispensable—one that will give not less than fifteen quarts of milk daily in flush feed, and soon after calving. Careful attention, embracing gentle treatment, regular feeding and milking, carding, etc., is another requisite. But with all these things she must have extra feed when the grass diminishes. Succulent food, corn stalks, millet, mown grass fresh from the meadow, are all very desirable if they can be had. If we must fall back upon meal, there is nothing perhaps quite equal to cotton-seed meal to start the milk, at the same price. The cow will probably not like it at first, but if it be mixed with Indian meal, or if it be scattered upon the fresh-cut grass she will soon learn to eat it. Many milkmen use one or two quarts a day, with great advantage. The manure made from it is very valuable, and is said by some to be worth the first cost of the meal.

Linseed oil cake is another excellent feed for milch cows used for this purpose and for fattening, much more extensively in England than with us. This also adds greatly to the value of the manure heap. If these are not accessible, use Indian meal, which is within reach of all. All these varieties of meal will add as much or more to the quality, as to the quantity of the milk. If it be an object to make butter for the family, it will pay to use meal very freely. If, however, we wish to preserve the cow for breeding and raising her calves, she should not be made too fat. There is little danger, if she have full supplies of succulent food with the meal.

Staking up Trees.

We need not argue the importance of properly tying up young trees, especially such as are exposed to winds, or to be jostled by passing men or cattle. It is undesirable to bind a tree directly to a stake, because it rubs and chafes against it as it is swayed by the wind. A tight band is not good, because as the tree grows the trunk enlarges, and the band is drawn too tight. The plan shown in fig. 1, overcomes these difficulties entirely, and affords, besides, very good protection against animals. Two stakes are driven near the tree, and a band of canvass, oil-cloth, or leather is passed from each about the stem. The winds may sway it back and forth a little in every direction, unless the bands are too tight, and the trunk may grow a great deal, while the only effect produced will be that the stakes will be drawn a little nearer together. Fig. 2 illustrates another plan not so good for tall stemmed trees, but better for short ones perhaps—although equally applicable to any. A band of straw is passed about the trunk, the ends twisted together for a foot or so, and then bound about a stake set 12 to 14 inches off. The stake must be set in the direction toward the prevalent high winds, and the stiff straw twist prevents much motion, even toward the stake. "As the *twig* is bent, so the tree's inclined," is an old saw, but one which never needs re-setting, however much the trees may. The worst eye-sore a thrifty farmer can have on his farm is a lopped down tree.

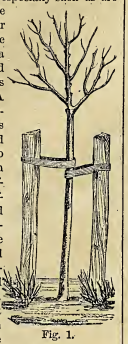


Fig. 1.

Fig. 2.

When and How to Bud.

Budding, we need hardly say, is the process of removing a bud from one variety of tree or plant, and inserting it in another. The object in budding is the same as in grafting, viz: to propagate a desirable sort of tree. The cion used in grafting is only a development of the bud used in budding. Fruit can generally be got by grafting sooner than by budding. But when a variety is very scarce, we can by budding get new limbs from single eyes; whereas, in grafting we have to use several eyes. The stone fruits exude so much gum in the Spring in northern climates, that it is hard to make grafts take. In all kinds of fruit, where grafting has failed or been neglected in the Spring, budding may be resorted to in the Summer.

The ordinary season for this work is from the first of July to the middle of August. But a more accurate criterion is the state of the buds and the bark. The shoot from which the buds are taken, must be of the current year's growth, and must be mature. This maturity will be shown by the forming of buds at the axils of the leaves, and of the terminal bud. The best buds for working will be found along the middle of the shoot. Many circumstances affect the condition of the buds and bark, and those sorts which come earliest into condition for budding must be first attended to, and of course others in succession. On some stocks and in some soils plums mature first, in others pears. Cherries may often be budded on Mahaleb stocks as late as Oct. 1st. The bark must be in a condition to lift easily from the wood, and there must be sap enough between the two to feed the young bud, and to help form a union with it. There must, also, be a certain degree of affinity between the bud and the stock. The pear, quince, apple, crab, and mountain ash, belonging to the same family, may be budded or grafted on each other. So with the apricot, plum, nectarine and peach. Currants and gooseberries may be worked on each other, and one sort of cherry on another. The practical operation of budding is simple. The method most commonly followed in this country is called *Shield Budding*, and is as follows: Having cut a cion containing the desired buds, (fig. 1,) choose a smooth, young stem, for the operation; and, if possible, let the insertion be made on the north side of it. With a sharp, thin-bladed knife, cut a slit through the bark about an inch to an inch and a half long, and with a cross-cut at the top, the whole shaped like the letter T, (fig. 3.) Then, from your cion, slice out a good bud with a little of the bark and wood attached, as in fig. 2. Now, with the other end of your budding knife, (if you use the common one), raise the bark of the stock, and slip the bud into the slit, and press it down to the bottom of the cut, leaving it so as to look like fig. 4. Be careful not to bruise the bud or the adjoining lips of the bark. Finish the work by tying down the bud and bark with bass-matting or soft woolen-yarn. Let the whole wound be well covered, so as to exclude air and moisture except from the point of the bud (fig. 5.) This whole operation should be done quickly. If the bud is long exposed, it dries, and is less likely to grow. A round minute is full long enough for the operation. A smart budder will insert and tie 600 to 1000 buds in a day, and if he has boys to tie after him, 2000 to 3000. It must be done expertly, too. If the bud has any torn and ragged edges, or if the wood under the slit is bruised with the knife, expect a failure. Where one has but a few buds to insert, he should choose a cloudy day, or the moist hours of morning and evening.

Fig. 1.

Fig. 2.

Fig. 3.

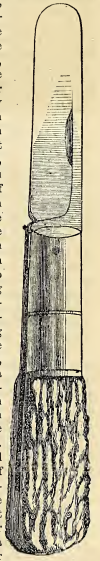
Fig. 4.

Fig. 5.

After-Treatment.—In a fortnight after the insertion, examine the buds to see whether they have "taken." This will be shown by their plumpness and freshness. The bandages should then be loosened a little, to allow room for expansion of stock and bud. Early the following Spring, cut off the stock with a sloping cut two or three inches above the bud. The bud will then push with much vigor.

The Best Budding Knife.

The common budding knife, having a long flat ivory handle for lifting the bark after the cut is made in the stock, is very inconvenient in rapid work, as it requires turning end for end at every operation. The knife, of which we give a full-size illustration, is far better, the blade answering the double purpose of cutting the slit, and lifting the bark, and the whole knife being no larger than can be conveniently grasped in the hand when open, the thumb resting upon the blade. The cutting part extends half around the end, and two-thirds of the length of the blade. That part of the end not sharp, is smooth and rounded, so that after the cut is made, this part may be slipped up under the bark on one side of the slit, and down on the other, just enough to start it. The cross-cut being made first, the other operations follow in very rapid succession. The buds having been cut from the stick, are held, half a dozen at a time, between the lips, and in a shorter time than we can describe it, may be inserted in the stocks. This knife is in common use in some of the nurseries about New-York. Our attention was first called to it by Mr. A. S. Fuller, of Brooklyn, who has been active in introducing it. We know of no place where it can be bought, but any cutler will insert such a blade in a common handle. The danger of bruising the young wood by the knife is very slight, for if the bark parts freely it is only necessary to start it by a slight lateral pressure, first on one side and then on the other, toward the top of the slit; the bark will be lifted enough to let the bud slip in, which, as it is slid down into its place, loosens the bark still more, if necessary. It is a good plan to polish the blunt edge of the blade used for lifting the bark.



For the American Agriculturist.

Hogs in the Apple Orchard.

Nobody sends such apples to market as my neighbor John Jacobs. He always has apples to sell and gets the highest price. Folks prefer fair, large apples; and such are always packed in Jacobs' barrels. You might search them with a candle and not find a knotty fruit or a worm hole. Such Rhode Island Greenings and Roxbury Russets I have never met with in the old States. They are as handsome as any thing in the virgin soils of the west.

I was going by Jacobs' orchard last Summer, and I had the curiosity to call and examine for myself. Says I, "Neighbor, what is there in your soil that makes such smooth, large apples? They are a third bigger than any thing I can get, and my trees look as well as yours."

"The secret is not *in* the soil," John replied, with a twinkle in his eye, "but on it. Do you see those grunters there? My pork brings me fifty cents a pound,—eight in flesh, and the balance in fruit. I began to pasture my orchard ten years ago with hogs, and since that time I have had no trouble with wormy fruit. Apples, as a general thing, don't fall from the tree unless something is the matter with them. The apple-worm and curculio lay their eggs in the fruit, and the apples drop early. The pigs devour the apples, and by September every unsound apple is gone and I have nothing but fair fruit left. The crop of insects for the next year is destroyed by the pigs. They root around under the trees, keep the soil loose, manure the land some, and work over what manure I spread. The apples help the pigs, and the pigs help the apples."

I saw John's secret at once, and have profited by it. I never had so few insects as this spring, and I give the pigs credit for it. In turning the orchard into a pasture put in *pigs*,—not landpikes with snouts like levers. You might lose trees as well as insects in that case. But well bred animals, with judicious snouts, will root in a subdued and christian-like manner. JONATHAN.

Perfect Trees.

These are almost as rare as perfect men. In the forest, all trees are crowded together, making only tall, naked trunks with heavy tops. On the outskirts of the woods they are one-sided. In the open fields the ease is often different. Here we occasionally see a tree which has had a chance to grow from the first as its nature demanded. Perhaps it is an elm. Its stately trunk rises aloft, braced up as it were by buttresses; then it divides into columns, spreading upward and outward on every side, and at the extremities, bending over and hanging down its graceful swaying branches—a perfect canopy of verdure. So the maple, beech, linden, and ash, occasionally present specimens of perfect development. And how pleasing is the sight, in contrast with the tall, lank, one-sided trees so common!

Perfect evergreens are still more rare. And this, because their perfection requires a uniform development of branches from the top to the ground. This, of course, is never seen in the woods, nor yet in the open fields, because strolling cattle and the farmer's ax forbid the growth of limbs within six or eight feet of the ground. We would by no means criticise harshly those which we do see, incomplete as they are. The contrast, on the wooded hills, of pine and fir with the lighter foliage of other trees is pleasing at all seasons, and never more so than in Autumn. But in the sense we are now considering, they are quite defective. Here and there, in the show-grounds of a commercial nursery, or in the lawns of fine country places, we see what approaches perfection. The tree is a complete pyramid. Its lower branches are the longest, and they lie, for the most part, on the smooth grass. From these up to the very apex, the limbs shoot out on either side, according to their own laws, swaying about at their own sweet will, a luxuriant mass of verdure. No two species or varieties of conifers are precisely alike; so there is no danger of monotony, even if all are allowed to grow in this way.

A tree so developed, whether deciduous or evergreen, is a pleasant sight. It seems to be answering the end for which it was created. It seems really to enjoy itself; whereas, a one-sided, dismembered tree awakens a painful sympathy. You feel as if the poor thing were only half a tree, and were suffering from hard usage, and might about as well be hewn down and cast into the fire. Nearly all our village and city front yards, and our cemetery lots, furnish sad illustrations of our subject. Now we desire, in our humble way, to inspire a better taste. The farmer and land proprietor should take special pains to save the fine trees which they chance to possess. In selecting young trees for planting, care should be taken to choose only well-shaped, vigorous specimens. Nurserymen should not crowd their stock into close rows, thus spoiling the symmetry of their trees; and if they do, planters should refuse to buy them.

Summer Pruning.

Now is the time to attend to this work. Yet it can hardly be called "work," for it consists chiefly in pinching off the ends of growing shoots, and can be done mostly with thumb and finger. Mr. Barry aptly styles it "antelipated pruning." Surely, it is better to *prevent* the growing of a limb in a wrong place, than first to allow it to grow all summer, and then cut it off; for in the latter case, there is both a loss of time and a waste of the tree's forces. By preventing the growth in one direction, we send its strength into another channel. We accomplish results in one year, which it would otherwise have taken two years to effect.

Here is a pear tree, on which the limbs seem perversely inclined to push out unduly on one side. Let us head them off at once, and encourage the development of buds and wood on the other side. We wish to train our pear trees into pyramids, with one central, leading shoot; but often a side branch grows more lustily than the central. By pinching it back several times we can keep it in place.

Here is a grape-vine with several shoots pushing out strong from a single joint, while at another, equally important, there are none, or very weak ones. Pinch out all but one from that cluster of buds, and pinch them a second time, if they start again. Here, also, is a fruit-tree which makes an abundance, yea, a superabundance of wood growth, but yields no fruit. What can we do, that will tend to throw it into a fruiting state? Try root-pruning, or try summer-pruning. By some means check the over-growth of wood-buds; this compels the accumulation of sap in the remainder of the buds, and converts them into fruit-buds. English fruit-raisers practice what they call *spurring-in*, on their trained trees, and find that it makes them very productive. This is founded on the principle we now advocate. Doubtless this practice was suggested by observing the fact that when the ends of a limb get broken or bruised during summer, it often becomes a fruit bearing limb the following year.

There is another sort of pruning which may well be done in mid-summer, viz.: the shaping of all kinds of trees by the removal of limbs and twigs, large and small. Ornamental and fruit-trees are sometimes neglected in their early growth, and it becomes necessary to take hold of them with a vigorous hand, and bring them into good form. This is often done in Spring, but not wisely. The injury from bleeding, the poisoning of the adjacent bark and wood, and the slow healing of the wound are all against severe pruning in Spring. Prune in mid-summer, and these difficulties are obviated.

With facts and principles like these in his mind, we counsel the reader to try his hand at pruning. We think he will not go amiss.

Tim Bunker on Stealing Fruit and Flowers.

"Where did you get them lalock blossoms and roses?" asked Seth Twiggs, as he saw Kier Frink driving home his empty coal cart, with his horse profusely decorated. There was a large branch between his ears tucked under the bridle, and a dozen or more of Dea. Smith's large damask roses nodding from the hames.

"Shouldn't 'zactly like to tell. I'm 'fraid you'd all be arter 'em, they're so handsome."

"Well, I can tell, you scoundrel," said Seth, as he tucked his stub of a pipe into his pocket. "The roses came from Dea. Smith's, and the lalocks from my yard, and they haven't been picked more than five minutes. You miserable White-oaker and thief, don't you know any better than to steal such things? I'll have you sent to Har'ford, for theft, sure as I am a live man."

"I should like to see you do it. They are nothing but posies, and haven't any more vally than the smoke of yer pipe, Mister Twiggs. They hung over the road tu, and I should like to know if anybody haint a right to what grows in the road. I wanted to make the ole hoss look kinder gay, and bring home something nice to the old 'oman and the young ones. I didn't mean any harm."

"Harm? you miserable scape grace!" exclaimed Seth, shaking his fist; "I would rather you'd taken the calf out of my stable, or the pig out of my pen. Didn't wife plant that bush, and hasn't it been growing these four years, and now it is all broken and ruined, and the flowers hang on that wretched carcass of a coal horse. It's enuff to make a Christian swear to see lalocks and roses put to such a use. If there is any justice, you shall go to Har'ford jail."

There, you see, was the rub. Seth Twiggs got angry to very little purpose. There is no law that touches these vexatious trespasses upon flowers and fruit;—or if there is, we have no public sentiment to enforce it. The majority of the public, even in this Commonwealth, which I am bound to believe is head and shoulders above any other in this respect, have no taste for flowers and the finer kinds of fruit, and they look upon the people who cultivate these things as lawful prey. Their own flower gardens are limited to a patch of bouncing bet and tanzy in the back yard, with may-weed and catnip in front; and as they do not attach any particular value to these things, they think their amiable neighbors who cultivate roses and flowering shrubs prize these just as little. They would as soon break down a moss rose in a neighbor's yard, as a sweet briar growing by the road side.

They admire gay colors and sweet odors as most savages do, and that is the extent of their taste for flowers. They have no other measure of value than money, and as flowers in the country do not sell in market, they have no value. A pound of butter brings twenty cents, and is worth the money. A rose, though it affords pleasure to the eye, and to the smell, and gratifies our love of the beautiful, brings no price, and is therefore worth nothing.

It is pretty much so with fruits, though there is a little more conscience about stealing them, for fruit has a money value, though it be small. Apples are common even among these rude people; but they are of the ungrafted sorts, and hardly pay to carry to market where the better sorts are known. But they think their neighbors prize fine pears, grapes, and the smaller fruits as little as they do their seedling apples. It was only yesterday that I found a woman and her two children in my strawberry beds, helping themselves as leisurely as if they had been picking in a cow pasture. They had brought their baskets with them, and had got them nearly filled, when I had to lay down the law to them. They had at least a dollar's worth of my property, and were about to walk off with it.

Now I don't want to say a word agin' Hookertown, or damage the reputation of the place. I suppose it is a full average of Connecticut towns, and in some respects a good deal better. But to speak the plain truth, there is a good deal of stealing among us in this small way. And it can't be laid to the door of the pulpit neither. Mr. Spooner is faithful—preaches total depravity just as hard as if people did not illustrate that doctrine themselves—warns, entreats and expostulates with all long-suffering and patience. But you see the most of these people don't come to meeting, and the preaching that is going to reach them, I guess, will have to be in men's lives rather than in meeting houses.

The notion that nothing is of any value unless it will sell, seems to lie at the bottom of a good deal of this wickedness, and I think a word or two ought to be said upon it. Now this may be true with a great many people. They are so mean that they would skin flints to make money. But among decent christian people this can't be so. A man prizes a good many things that have no money value, far more than if he could turn them into gold. There is an old lap stone, such as shoemakers use, in my garret, that belonged to Sally's grandfather. He used to use it, and when she was a little child she remembers seeing the old man pound leather on it. Now I don't suppose the stone would sell for a red cent, but Sally says she would not part with it for the Kohinoor diamond, and all the crown jewels of Victoria. She is an honest woman, and I am bound to believe her. Anything that our affections enter into has a value that can not be measured by dollars and cents; and to rob us of these things is to do us a greater injury than to steal sheep and horses. I can't blame Seth Twiggs for raving about his lilac bush. His wife planted it and had a right to rejoice in it. It was rather hard to see the growth of years destroyed in a moment by an ignorant boor.

We cultivate flowers and learn to love them for their beauty, and for the pleasure they give our wives and children. They cost considerable time and money, and really give more pleasure than many things that cost ten times as much. They are associated with our leisure hours, and our domestic enjoyments. They seem to belong to the better side of our natures. We have a moss rose under our bed-room window that little Sally planted when she was a school girl. It hangs full of blossoms every year—not worth a cent. But I declare I had rather lose a half dozen of the best apple trees in my orchard than that worthless shrub.

It is very much so with our nice garden fruits. We raise them because we can't buy them in the country, and don't want to beg or steal them. I cultivate grapes and pears, and get a good deal interested in the vines and trees. I spend days in training them, and enjoy my power over them. They have a value to me above the market price, because they are the product of my skill. I have watched that bunch of grapes from its blossom to the purple bloom upon its ripened berries. I have watched those ruddy cheeked pears quite as anxiously, and anticipated the delight of setting them before my friends, when they pay me a visit. When the friends are gathered for the feast, it is a sore vexation and disappointment to find the fruit missing. We need more efficient laws to protect us against fruit and flower thieves, and above all a wider diffusion of a taste for these things, which will prove the best safeguard against their loss.

Hookertown, June 14th, 1862.

Yours to command,
TIMOTHY BUNKER, Esq.

Horticulture Artificial.

A young farmer writes us that he thinks nearly all the operations of horticulture artificial. They interrupt and prevent nature's laws and processes, and so induce disease, decay and death. He inveighs against pruning, grafting, budding, cutting off the tap-root of seedling trees, manuring, etc. Why not allow trees to grow naturally, and vines to clamber unrestrained over tree-tops and hedge-rows, and all to get along without any extra fertilization? There is a grain of truth in our young friend's theory, but hardly enough to keep it ballasted.

As to the tap-root; suppose we did not cut it off while small, in the nursery row, who could transplant the tree when it had grown a few years? The tap-root would be far down on the road to China, and the side-roots would be very small. As to budding and grafting, it is very true that crab-apples, choke-pears, and other wild fruit will answer to keep men from starving, but they will not quite satisfy the common wants of civilized people. As long as grafting will give us a plenty of Seckels and Northern Spys, very naturally we shall try to get them, "unnatural" as the process may be.

As to pruning and training, doubtless this is sometimes overdone, but perhaps it is as often wholly neglected. Some kinds of shade trees take a very straggling, lop-sided habit, and need a little improvement in their manners. Some fruit-trees make excessive wood-growth, and need a little cutting back, at the proper time, to induce fruitfulness. Of course, we could have no hedges, without the pruning-shears. The grape vine would yield us only small, second-rate fruit, if we allowed it to run wild on the trees; but it gives us more and better fruit, if confined to the trellis; and certainly it is easier to gather. A pasture or hay field is all well in its place, but a smooth lawn, well graded, mown and rolled, is a far finer sight for the neighborhood of the house. A gravelled walk, a bed of flowers, or even a cornfield, all are artificial.

And so we might go on; but our friend will not need further argument or illustration. Nearly all our agricultural and horticultural operations are artificial, but no reasonable man condemns them for that. Yea, even our moral virtues are artificial, in the sense of being "contrary to nature," but we prize them none the less for that. Rather, are we profoundly thankful to the Great Husbandman whose loving care has grafted them upon the wild olive tree.

Skilled Labor for the Garden.

There are some who, for various reasons, can not or will not work. They must depend chiefly on hired labor. And if they wanted only the plainest kind of work done, this could be easily got along with, for there are scores of laborers at every corner waiting to do this. But when it comes to such work as planting hedges and training them, pruning grape-vines and pear-trees, laying out flower-gardens and setting out shrubs and plants, how few laborers can be trusted! The good natured merchant directs Patrick, in the morning, to set out a few rows of dwarf-pears, and several grape-vines, and then goes to his place of business, flattering himself during the day that all is going on well. But on coming home, at evening, he discovers that the rows are as crooked as a rail-fence, and on examination finds the roots of his vines and trees jammed into little post-holes, then covered with soil, and spatted down very smoothly! "Faith, sir, that's the way I usht to do it when I was head-gar-r-dner to the Duke of Devonshire."—And so it goes, day after day bringing its several blunders, until the poor man is worried almost to distraction.

In all our villages and large towns, there are many families who are unable or disinclined to keep regular and permanent hired men, and yet have more or less gardening to do all through the Summer. They want their seeds sown in the Spring, then their hedges trimmed, or their grass-plot mowed, and their gravel walks cleaned. Widow Smith wants her lot in the cemetery put in order; Dr. Jones must have his grape-vines pruned and tied up. Nearly all of these persons know little about gardening, or have not the time to superintend it.

Plainly, then, we want not only laborers, but skilled laborers,—men with brains as well as muscle, and with both brains and muscles trained to do a specific kind of work. Were we better supplied with such workmen, our country homes would be managed with more ease, and with greater satisfaction to their owners. The professional or the business man could then go to his daily employment feeling that his garden and lawn will not be spoiled during his absence. Our grounds would rise to a higher point of excellence in their arrangement and keeping.

How best to multiply such a class of laborers, we hardly know. They must be trained somewhere, for they do not grow spontaneously. In the commercial nurseries, and large gardens near cities, and on the finest country-places of the land, there are many young men who, by a little pains on the part of their parents or overseers, might soon be trained into intelligent, skillful gardeners. If then, they should advertise in the leading agricultural and horticultural papers, they would surely find lucrative places. Would that many young laborers, now content to do only the commonest kinds of field work, would learn the art of gardening. It is an honorable, pleasant and profitable employment. The result even then would be that more lucrative places would offer so freely to this class, that the want we allude to would still go unsupplied. The only remedy after all, seems to be a diffusion of practical knowledge of gardening among all educated people, affording them enjoyment, exercise, and ability to direct laborers.

CHILDREN AND FLOWERS—*Engraved for the American Agriculturist.*

The love of flowers is to be cultivated, not extirpated, as is so often attempted by ignorant or heedless parents. It is not a proof of depravity that your child loves to ramble in the meadows and woods after lilies and wild roses, more than to hoe potatoes and corn. He does not deserve a thrashing, because he lingers by the roadside to pluck violets and dandelions, when he is sent to turn away the cows. He can not help admiring the dew-drops that hang like jewels on the flowering grass, and the morning songs of the birds. His soul is full of boyish rapture, and he is unconscious of the passing moments. He does not deserve ridicule, or a scolding, when he asks for a patch of ground where he may plant rose bushes and flowering shrubs, pinks and asters. It may be that the potato blossom, or rather bulb, has more charms for you than all wild flowers, or exotics in the garden. The children have not learned to measure by your standard. They will find pleasure in things that are good for nothing but to look at, and smell of. They are taken captive by the delicate coloring of the petals, and the aroma of the opening flowers; and who shall say that they are not as rational in their admiration as the man who measures value by the market price in gold? For what has God given us these instincts, if they are not to be gratified and developed, and have their appropriate place and exercise in forming the symmetrical character?

It is a good plan to give children portions of ground near the house to plant with flowers and flowering shrubs. It does not necessarily involve much expense or patronage of the nurseryman. With a little encouragement they will supply themselves from the meadows and woods in their own neighborhood. Let them transplant violets and butter cups, blood root and lilies, golden rod and cardinal flower, winter green and prince's pine. There are hundreds of pretty wild flowers that will flourish in the garden under their care, and make home attractive. What can be finer than the azaleas, the high and low laurel, and the rhododendron? They will bring to light many gems of the field and forest unknown to you, "flowers that waste their sweetness upon the desert air."

This love of the beautiful is to be educated, and if we will but give nature in them a fair chance, the education will not be half so expensive as that of the schools. Let them have occasional holidays, the boys and the girls together, in which they may go after flowers and berries in the woods and meadows, and by the mountain streams, and enjoy nature to the full. Picnics are in season now, and we have sometimes thought that they did old folks quite as much good as young ones. The perfection of a lesson in esthetics, is a dozen families or more, parents and children together, encamped in a wood on a Summer's day. It costs comparatively little in the way of preparation, but pays abundantly—the children can tell you in what.

Bouquets Gratis.

Every person who owns a good flower garden, is annually beset by visitors asking for bouquets. In some cases the flowers will be appreciated, but in many others, not. Many want them to pull to pieces, or to carry up and down the street, and finally to throw away. To such persons, it is hardly worth while to give choice flowers, if indeed any: it is money and labor, and rare beauty and fragrance thrown away. Many of these "beggars" have land enough at home, but are too lazy, or have too little real love for flowers to make gardens for themselves. They like very well to come and avail themselves of the fruit of your time and industry. Now, for these, and all other persons who do not appreciate the real worth of flowers, we would say, give them nothing, or else have at hand a lot of cheap, showy plants from which one can cut to *their* satisfaction. The marigolds, the annual larkspurs, monkshood, Drummond's phlox, candytuft, scabious, etc., will furnish a good assortment. Give them these, and it may awaken a love for something better.

But to others who heartily love flowers, and who will appreciate and preserve the bouquet given, as long as it can be kept, we would say, give choicer kinds. The finest roses, carnations, verbenas, geraniums, heliotropes, and others of sweet perfume and delicate beauty, should be freely bestowed. They will confer great pleasure, and will strengthen the ties of friendship.

Summer Fruits.

The season of fruit is one which gives employment to all who take any interest in their cultivation, in investigating new varieties, and extending one's acquaintance among those prized or cultivated by his neighbors. Every spare hour may thus be profitably spent. The strawberries are already past, and the lessons of the season have been well learned, we hope. Certainly, the value of the fruit to the public was never before so well demonstrated. The first week in July finds cherries in their prime over most of the country; and when any one who has been in the habit of esteeming the black and red mazzards, which are to be found almost universally over the country, as delicious, first enjoys a taste of the Black Tartarian, Black Eagle, or several of the Bigarreaus, it is almost as though an entirely new fruit had been

introduced to his notice. The more one knows of varieties of fruits, and the more one studies their peculiarities of flavor, the better is he able to appreciate their differences. When a man finds out that the grapes which he gathers on the mountain, and enjoys so well, are considered by those who claim to have a cultivated taste as next to worthless; and when he sees that with the finest of fragrant clusters he can not tempt them to taste a single one, no wonder he says: "Out upon such delicacy of taste—it is whim and nonsense." Still it is no nonsense. The taste, properly cultivated, affords us very refined enjoyment, and this too without the temptation to eat too much. He that eats any thing with pleasure, will be almost sure to gluttonize. He that enjoys only the very best fruit, has a higher enjoyment, is more benefitted, and seldom or never eats fruit to excess. These remarks apply equally to all kinds of fruit. At this season, study particularly currants and raspberries.

Double Yellow Butter-Cup.

This is a variety of the common butter-cup, (*Ranunculus acris,*) made double by cultivation. The cut gives a very good idea of the size and form of the flower—which is very perfect, and retains the brilliant color and gloss of the wild variety. It is perfectly hardy, growing in any common garden soil, and is propagated by dividing the roots, either early in the Spring, or so soon as it is done flowering in Summer. It is well worthy a place in the garden.

Endives, Culture, etc.

Green salads are, at all seasons of the year, very refreshing and healthful articles of food. At the very head stands lettuce, particularly those kinds which form heads readily: but few or no kinds will bear the heat of Summer. They will not head, acquire a disagreeable bitter taste, and are tough. The delicious salad named above comes in to supply the place of lettuce during the heats of August, and remains in perfection during the Autumn and Winter. It may be sowed at any time during the Summer, up to the first week in August, needing good deep rich garden soil, frequently stirred. There are several kinds. We prefer the broad-leafed variety. Sow in drills, and transplant 12 to 14 inches apart. As the plants grow they may be watered with liquid manure, and if the ground is well and frequently hoed, they will grow rapidly, spreading out a mass of leaves, lying flat on the ground, 12 to 14 inches in diameter.

If wanted for summer use, when they have attained the size of a dining-plate, the leaves are gathered together when dry, and tied with a piece of bass-matting or string. After a heavy rain, should one occur by which the inside of the plants are wet, they must be unbound and opened to dry in the middle of the day, and bound up again before the effect of the bleaching is lost. The blanched portions form a very pleasant summer and autumn salad. The chief excellence of the endive is seen in Winter.

After frosts have cut down tender things in the garden, we pull up the endives, remove any decayed leaves, and set them out in the sand-beds in the cellar, closely packed together. Very soon they begin to grow, and the new growth is beautifully blanched, while the tenderer portion of the older growth bleaches also. The largest and most vigorous plants are earliest fit for the table, and others follow in succession. We heartily commend the culture of this salad, which is so great a favorite upon European tables. There is always a ready market for the bleached plants among our German population.

Mushroom Culture.

Mushrooms are greatly esteemed on account of their peculiar and delicious flavor. They may be stewed, fried in fat, or made into catsup. In some countries, Russia and Poland among the number, there are said to be above thirty kinds in use. They are there gathered at different stages of growth, and used raw, boiled, stewed, roasted, and even dried for winter use. Great care must be exercised in selecting mushrooms for eating, as there are poisonous kinds. Three ways are recommended by which to determine whether they are good: 1st, by the color of the gills, that of the good kinds being, when young, of a fine pink, or flesh color, changing, however, to that of the questionable kinds—a chocolate color—at more mature growth; 2d, by the smell, the good kinds emitting an agreeable odor, while that of the bad is nauseous and disagreeable; and 3d, by sprinkling salt upon the inner or spongy part, unwholesome kinds turning yellow, and edible kinds black. Bad kinds are found mostly in forests; edible ones in open pastures, most frequently in old horse-pastures, which sometimes, in damp, warm seasons, yield large crops.

Mushrooms may be grown at any season of the year, by those who have a suitable bed. This may be made in any dry cellar, (or under a shed,) the temperature of which can be kept at from 50° to 60°. Extremes of temperature must be avoided. The temperature of the bed should be from 70° to 75°. A bin or bottomless box about 20 inches deep is suitable for a bed, and one four feet wide by eight feet long, if properly managed, will yield a supply for a good-sized family. On the bottom put a thin and slightly oval layer of ashes and gravel, or pieces of bricks, to avoid dampness. Next put in a six-inch layer of unfermented horse-droppings from grain and hay-fed horses, (not grass-fed,) the dryer the better, with short straw intermixed. When this, being exposed to the air but not to rains or dampness, has become quite dry, cover with two inches of dry earth—sandy, if possible; into the surface of this introduce small pieces of spawn in rows six inches apart. Then repeat the layer of horse-droppings, and short straw, and of earth, with spawn introduced as before. Cover the whole with two or three inches of fresh, warm horse-droppings, and occasionally sprinkle with blood-warm water, to induce fermentation, the top layer of fresh manure to be removed as soon as fermentation has caused the spawn to begin to spread. In five or six weeks mushrooms may be expected. The usual size is from 1½ to 3 inches in diameter, but those over 4 feet in circumference, and weighing 12 to 14 pounds have been produced.

Mushroom spawn is usually to be had in seed stores, and also may be found, of uncertain qualities, however, in dry lumps of horse dung, in old pastures, hot-beds, and manure heaps. It has the appearance of dry, white threads. The following method of manufacturing sale spawn is recommended by Bridgeman: "A quantity of fresh horse droppings mixed with short litter, should be collected; add to this one-third of cow dung, and a small portion of good earth, to cement it together; mash the whole into a thin compost, like grafting clay; then form it in the shape of bricks; which being done, set them on edge, and frequently turn them until half dry; then with a dibble make one or two holes in each brick, and insert in each hole a piece of spawn the size of an egg; the bricks should then be laid where they can dry gradually. When dry, lay dry horse-dung on a level floor, six or eight inches thick; on this, pile the bricks, the spawn side uppermost. When the pile is snugly formed, cover it with a small portion of fresh warm horse-dung, sufficient in quantity to produce a gentle glow through the whole. When the spawn has spread itself through every part of the bricks, the process is ended, and they may be laid up in any dry place for use. Mushroom spawn, made according to this recipe, will preserve its vegetating powers for many years, if well dried before it is laid up; if moist, it will grow, and soon exhaust itself."

Mushrooms of good quality find a ready sale in New-York, and doubtless in other cities, if the discretion of the gatherers or raisers may be depended upon; and they would soon become a favorite article of food if they were more commonly cultivated for the market.

Raising Cauliflowers.

Not the least among flowers is the savory cauliflower. So every epicure will say. So every one who enjoys good food will say, and so say we. To grow this vegetable well it is important to give it some care. Start the seedlings, as we do common cabbages, in a warm rich border. For winter and fall use, the plants need not be set out before the 10th of July. Prick them out once or twice in the border, before giving them their final place in the open ground. This will make them strong and stocky plants. In choosing a spot for transplanting them, let it not be in the shade of trees or fences. The soil should be deep and rich. If not so naturally, break it up with a long spade, and put a shovel full of manure at the bottom of each hole, covering the same with two or three inches of fine earth. With a garden trowel, lift the plants and set them out in rows three feet apart, and two feet and-a-half in the row. If the weather be dry, shade them for a few days. Keep the ground loose by hoeing, but do not earth up the plants much, as this often induces rot.

Unless the ground is naturally moist, it will be well to cover it in mid-summer with strawy manure, or with clean straw. Once a week, pour over this mulch the refuse water of the kitchen and chamber. In September and October you will enjoy the results of these labors.

Garden Culture of Celery.

This old British salad is a great favorite with epicures, but it is less generally cultivated than it deserves. Probably it can not be shown to contain much real nourishment for man or beast, yet it makes a fine relish. The stalks, when blanched, may not only be used raw, or for salad, but may be stewed or used for seasoning soups. In its wild state, it grows in marshy ground and by the side of ditches, where it is known as *smallage.* In that state its taste is rank and coarse, but when cultivated and bleached, it becomes delicate, sweet and crisp.

There are many kinds for sale at the seed-stores, advertised as Mammoth, Giant, Excel-

sior, etc., but they may all be reduced to two classes, the *White Solid* and the *Red Solid*. The only difference between these is in their color, and the ability of the red to stand frost a little better than the white, and its being more uniformly solid, while the white is more delicate in flavor. The difference in size is the result of cultivation entirely.

To secure good plants, the seed is best sown in a cold frame, and when an inch or two high, pricked out into the open ground, in a warm, sheltered border, and it is well after ten days or two weeks to move them again, leaving the plants three or four inches apart. These several transplantings make them stocky and harden them off for final setting in the trenches in June or July, or even as late as the first of August.

For planting, choose a rich and level piece of ground, dig the trenches eight inches or a foot deep, a foot wide and three feet apart. Remember to throw the top-soil on one side of each trench by itself, and the poorer soil on the other. The trenches should, if convenient, run north and south, though this is not essential. Give the ground in the bottom of each trench a thorough enriching with old manure; leaf-mold mixed with the remains of an old hot-bed is the very best thing. Having watered the plants thoroughly the evening before, they will be in good condition to take up. Use a garden-trowel, taking up as much dirt as possible with each root. Some recommend clipping the loose leaves and the extremities of the roots on re-setting. Let the plants stand in the trenches four or five inches apart. If the weather is hot and dry, water the ground well, and for a while lay a few loose boards over the trenches by day.

The after treatment is simple, yet it is of the utmost importance that it be rightly done. Keep the ground well stirred with the hoe, that the plants may grow rapidly; if the weather is dry, watering must be resorted to. Do not be in haste to "earth up." About the middle of August or first of September, is soon enough. In doing it, hold the leaves of each plant together with the left hand, and with the right draw the soil around the stalks several inches high, using the best soil thrown out of the trench, rejecting the poor. But use the greatest caution not to draw the dirt into the center of the stems, as this will cause them to rot or become very rusty; and do not *press* the soil too much towards the stalks, as this will check their growth, but it must be tightly packed down in order to turn the rain. Repeat this earthing up once a fortnight, using the same care in doing it.

Before hard frosts set in, in the Fall, the plants should be lifted, taken into the cellar, and set out with little earth adhering to the roots, in nearly dry sand. They will grow and blanch in the cellar, and may be used for many months.

Movable Frame Bee-Hives.

It is well known to all bee-keepers that bees ordinarily build their combs in more or less uniform perpendicular cards or curtains, about 1¼ inches from center to center. If guides, made of thin strips of comb regularly fastened to the top of any chamber of the hive, are provided, these will be followed, and the combs made with similar regularity. Where any rather rough edges are similarly presented, the result is the same. The cards of comb are attached to them, and if the edges are straight and not too far apart there will seldom be any considerable irregularity. In all movable frame hives, the aim is to present such edges at proper distances, so that the bees may economize all the room in the hive, and that we may remove any one or all of the frames with the comb attached at pleasure and without disturbing the other combs. This, Mr. Langstroth accomplishes by using oblong frames, like slate frames, the upper edges of which, when in position, are so much longer than the frames that the frames may be suspended by them in a box. Others use frames of different shapes, some arranged to draw out sideways, which is attended with many inconveniences; others are triangular to accommodate slanting floors which facilitate efforts of the bees to keep the hives clean; and another plan is to have the frames hinged, so as to be swung apart when the hive is opened, like leaves of a book held perpendicularly. For these and other forms and combinations with them, of various supposed or real advantages, letters patent of the United States have been granted. But the fundamental idea of movable frames, which the inventions of Mr. Langstroth first rendered practically useful in this country, was early in the present century put in practice by Huber, a Genoese apiarian, and subsequently by others both in Germany and Great Britain. A person of ordinary ingenuity, living where the movable frame hives can not be bought, can easily adapt frames to a square box, taking care chiefly to present a rough, narrow edge (as left by the saw) for the comb to be attached to, and not allow the frames to come anywhere so close to the box that the bees will cement them to it, and taking care also not to give so much space that they will build a line of cells between the frame and the sides.

Keeping Swans.

Who that has seen the swans in the Central Park, in this City, or on the little lake in Mount Auburn Cemetery, Boston, does not wish to adorn his own pond or stream with a few of these graceful water-fowl? We are glad to learn that they are being introduced into the grounds of many private residences throughout the country. These birds are often called "tame swans," "domestic swans," and so on; but, let it be remembered, they are not so very tame, after all; they never become so quiet and home-loving as the goose or barn-fowl. They are constitutionally wild and capricious, and need watchful care; though apparently very tame and familiar toward those who feed them, or from whom they expect no harm.

At the outset, they must have good water-privileges. A lake, or a pond of good fresh water, will answer. Take no pains to clean out the weeds and rushes which chance to grow near the margin of the water, for it is among these that swans delight to ramble and feed. They love corn, oats, barley, etc., but their natural food is seeds and grass, insects, worms, larvæ, and mollusks. When grain is fed, scatter it just on the shore and in shallow water near the shore. They love the waste vegetables of the garden, and all the more for being half-decayed. Watch their eating habits, and you will observe that they prefer to eat by "suction," rather than by picking up their food like a hen. They love to dive their heads under water, and suck down the soft, half-rotted vegetation on the sides and bottom of the stream. Thus they act as scavengers, purifying the stagnant waters that would otherwise become foul and unwholesome. In Holland, they are considered very beneficial in this respect. If they will swallow down miasms and fevers for us, and harmlessly to themselves, we ought to thank them.

In buying a pair of swans, it is best to get young birds, for the old are hard to domesticate in a new place. But in purchasing cygnets, be sure and get birds of opposite sexes, a thing not so easy to determine by their plumage. Two males will quarrel, and two female-birds, though they live pleasantly together and lay eggs, of course will raise no family between them. Get husband and wife, and all will go off well. To ascertain the sex, put several cygnets into water, and those which swim deepest, (i. e. sink deepest,) will prove to be females. After fixing upon your pair, have them securely pinioned. And then, to prevent their flying away from your grounds some fine day, have the last joint of each wing taken off. Let this be done at the place of purchasing the birds, so that they may have no unpleasant associations with their new home. This can be done so as to disfigure the bird but very little. When they reach their new quarters, treat them kindly, keep them quiet, and feed them regularly.

The male bird is capable of increasing his kind when two years old; the female not until three years of age. When they show a disposition to breed, they should be supplied with a bushel or two of coarse litter, such as straw, rushes, stalks, and a few sticks. They will work this material up without any instruction. They lay from six to ten eggs before setting. When the female commences her maternal labors, nobody should approach her nest. The male bird will sail very proudly and defiantly up and down before the nest, and wo to the youngster who dares to approach the sacred bed!

A fat young swan makes a capital dish. From October to Christmas, these birds are in prime order for the table. After that period, they are not as good—the turkey excels them. Well fattened, they weigh, in their feathers, from 25 to 30 pounds. And now, hoping that we have got our readers into a good appetite, we leave the subject, intending to resume it again in due time.

Luncheon.

The habit of eating five meals a day during Summer, and especially in haying time, came over with our fathers from England. The custom perhaps originated in certain peculiarities of their climate. The summer days are longer than with us, and the fair days for gathering the hay and grain harvests are fewer. It was necessary for the laboring force of the farm to make the most of these fair days, and to work while the light lasted, sixteen hours or more. More food was necessary to sustain the body under such prolonged exertion.

Our work is severer in Summer than at other seasons—more so formerly than now, when the horse-reapers, and mowers, and rakes, have lifted the farmer's heaviest burdens, and put the hay and grain harvest completely within his power. Whatever apology there may have been for working fifteen hours a day, in the last generation, there is none in this. We do not believe anything is gained by more than ten hours of severe labor in the field daily. This, with the chores at night and morning, will be as much labor as the body ought to sustain, taking the season through. In a single day, a man may do more in fifteen hours than in ten. In a month we think the man laboring ten hours a day only, will accomplish the more. The overtaxed system must have rest, or break down. If it can not get it in the bed at night, it will take it in the field, inadvertently, if not willingly. There will be lagging, want of spirit, and slighted

tasks, showing that the energies are not in the work. Luncheon is for long days and over-work. It is based upon a wrong philosophy of labor.

With a better arrangement of the meals, and the hours of labor, luncheon may be dispensed with to the great relief of the women of the household, and to the advantage of employer, and laborers. The breakfast should be out of the way and the men be in the field by seven. They can work five hours comfortably, when six and a half would be an injurious strain upon the strength. They come to the noon meal at twelve, with a good appetite, and at one, are ready to resume work again. They work vigorously until six, when if they knew they were not to be dismissed until sunset, or dark, they would hold back. We have followed the ten-hour system with our laborers upon the farm for several years, dispensing with luncheon, and have no doubt it is good economy. With good calculation, it is seldom necessary to overstep these bounds. If a storm threatens, and more work is necessary to get hay into cock, or into the barn, men are always ready and willing.

Suggestions for Health-Preservation.

The season is now upon us when, owing to the summer heats and atmospheric influences, fevers prostrate, and diarrheas exhaust multitudes who, during less debilitating seasons of the year, are comparatively exempt from disease. Yet this class of complaints may generally be avoided. The readers of the *Agriculturist* should be well enough acquainted with the subject of Health-Preservation to know that it does not depend upon medicines. These would rarely be necessary, if we were as anxious to take care of our own health as a thrifty farmer is to take care of his sheep and hogs. Men are apt to employ less common sense in their own behalf, in this regard, than in behalf of their swine! They will carefully study and profit by information relative to the ailments of their herd, and how to avoid them, while the preservation of their own health, and that of their children, is a subject rarely thought of. Worse still, sparing neither pains nor expense to procure the most wholesome food for their animals, they debilitate their own stomachs with that which they *know* to be unwholesome. The general rules and requirements of health are simple and easily learned. In fact, one has but to watch the sensations of his olfactories, skin, and stomach, and *heed* them, to keep clear of all danger from ordinary diseases. The sense of smell warns him against inhaling impure air; the skin, by dryness, feverishness, or irritation, indicates a want of that frequent bathing, which is so essential to health; and the stomach calls for food when needed, repels it when enough has been eaten, and in a natural state, betokens generally that which is unwholesome. A little extra pains to notice these indications will greatly sharpen the perceptions.

It may be set down as a general rule that ordinary diseases can not obtain a foothold where only pure air is inhaled, the skin is clean and healthy, and the stomach kept in good condition. The latter involves the most difficulty, owing to the depraved habits of diet in "civilized" society. But a few rules, well lived up to, will rarely fail, viz: Be regular as to time of eating; do not exercise violently either immediately before or immediately after meals; and let the last meal of the day be light and easy of digestion, so that sleep may be undisturbed and refreshing. In the morning, any billious disturbance of the stomach is known by the bitter taste in the mouth. *Heed this warning*, by restricting diet to plain bread, vegetables, and ripe fruits; and if it increases, go without supper, and take a thorough warm water bath—rinsing off in cool water—just before retiring to bed. As a general dietetic rule for Summer, persons in any degree delicate should use plenty of ripe, raw, and cooked fruits at meals, and but little, if any, fat meats. Let all dietetic changes be gradual; and for the most part use food that requires chewing, *and chew it well*, in order to give the stomach the full benefit of the assistance of the saliva in digestion.

Avoid sudden changes in quantity of clothing, cooling off suddenly when heated and perspiring, and all sudden changes. In keeping the skin clean, do not neglect that most important part, the scalp.

For the American Agriculturist.

Taste in Dress.

Tight sleeves are becoming fashionable now on our prairies, where they are so much needed. Prairie winds are cold and searching, and loose sleeves in Winter, at least, are next to no sleeves at all. Flowing sleeves have been so long in fashion, however, that people are tardy in giving them up, though for housekeepers they are the most slovenly sleeves ever invented, not to speak of the shivering look they give in church or street, with short gloves, and bare arms as red as a lobster. Fur cuffs on bare arms is but one remove, but add white undersleeves, whether of muslin, or zephyr, and the change to the wearer and looker on is very great.

It is said that when a French lady, from the country, comes into Paris to refurnish her wardrobe, she puts herself and purse into the hands of a female *modiste*, who measures her, takes her stature, complexion, etc., into consideration, and to whom, at the end of a week, she returns for a complete suit of clothes. The French women are not pretty, as a general thing, but their charming taste in dress makes them queens of fashion the world over. And while some women are born with an innate perception of the beautiful, there are others to whom the harmony of colors is a dead letter. The other day I was shopping in Lanark, when I met a woman who came recently from the East; she had on a splendid *moire antique* dress, with a trail to it, which looked anything but at home in the muddy streets of our new prairie town. I glanced upward at her bonnet, it was a summer straw, with green trimming outside, pink roses inside, and *yellow* strings.

One of the prettiest girls I ever saw was a young lady with curly, red hair; some might have thought that the color of her hair detracted from her beauty, but I didn't; her complexion was such a mixture of the rose and lily, that her exquisitely dressed hair seemed a fitting accompaniment. She never wore distinct green, red, or blue dresses, as I have seen so many of her complexion wear. "What a blaze she makes," she said to me one day as we met a red-haired girl with a maroon bonnet and cherry-colored strings. There was truth in the remark.

Dark complexions seldom look well in distinct black or white bonnets; if the bonnet is black, crimson flowers or ribbon with a white ronche is a great improvement, and pink trimming always relieves a brunette complexion in a white bonnet.

Carroll Co., Ill. MRS. M. J. STEPHENSON.

Fruit in Bottles.

On account of their abundance and cheapness, we shall put up a large quantity of berries and other fruit this season. With most of them, the plan given in the June *Agriculturist*, page 181, will be followed, though we shall try a few of each sort simply bottled in water raised to the boiling point. Some of the pickle and preserve dealers keep them thus with entire success. The directions given are to procure the regular pickle bottles, with long necks, and without shoulders, and to use long, soft, close corks, that will admit no air. The bottles are filled with the fruit, and water poured in to within half an inch of the top. The corks, softened in hot water, are forced with a mallet at least an inch into the necks of the bottles. Tie the corks securely with two strings crossing each other. Then set the bottles upright in a wash-boiler of cold water reaching nearly to the corks, and heating the water, keep it boiling say five minutes, when they may be taken out and set away. We know of raspberries and other fruit having kept thus for two years.

Pleasant and Wholesome Summer Drink.

The juice of currants, put up in air-tight bottles, affords a foundation for a delicious and wholesome beverage. Put enough water with ripe currants to prevent their burning; heat in a preserve-kettle nearly to boiling; transfer to a bag suitable for straining and press out the juice; add half a pound of clean sugar to each pound of juice and boil, skim, and put up as recommended for putting up the fruit. The juice alone will keep as well, if not better than the fruit, and, mixed with from one to two parts water, according to the taste, it makes a most refreshing drink. Being entirely free from alcoholic or intoxicating properties, there is no danger of the creation of an appetite for strong drink resulting from its use. It might profitably be kept for sale by druggists at all seasons of the year, and we presume that putting it up for that purpose may be made a source of income worthy of the consideration of currant-raisers who now make wine. Those who usually have more of this abundant fruit than they know what to do with, may find it for their interest to take note of this suggestion.

Unleavened Bread.

D. M. Adams of Worcester Co., Mass., writes to the *Agriculturist* endorsing E. W. Knight's remarks on bread-making, and adds: "I am a dyspeptic, and must say that I have derived more benefit from the change from leavened to unleavened bread than from any other dietetic change that I have made. If our good Editor can not endorse it, I can to the fullest extent, and with his permission should like to give my way. I stir as much Graham meal as I wish to into water; if I want soft spongy bread to eat warm, I stir it quite thin, if to eat cold, I prefer it stirred pretty thick; it makes a much lighter, sweeter loaf than can be got in a more artificial way. [The mixture of flour and water, thus prepared, is, probably, then simply baked.—ED.]

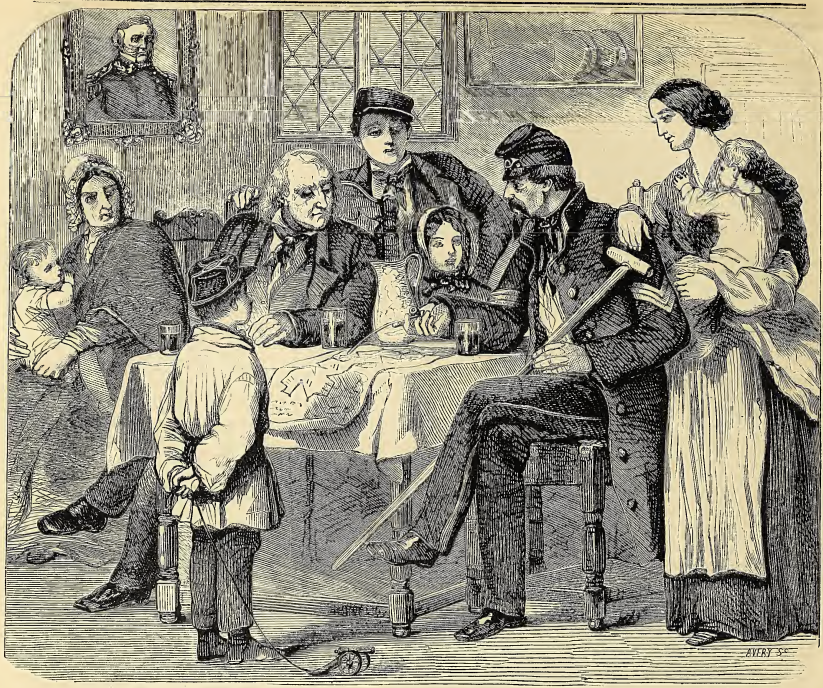
Various Recipes.

Flour Pudding.—The following is the recipe of a delicious, as well as a cheap pudding: 1 cupful of white sugar, 3 tablespoonfuls of melted butter, 1 egg, 1 teaspoonful of cream of tartar, ½ teaspoonful of soda dissolved in 1 cup of sweet milk, and 1 pint of flour. Flavor to the taste, and bake in a tin pan. To be eaten with hard or soft sauce. IDA J. RAYNOR.

Rhubarb Wine.—Take 4 lbs. of rhubarb to 1 gallon of water, squeeze it, put it into a tub, and pour the water on it; let it steep 3 days, then strain off the liquid; put 3½ lbs. of sugar to every gallon, and put it into a barrel, stir it every day for a fortnight, then add a few raisins and a small quantity of isinglass, then bung it up for three months. Finally bottle it, and in 5 or 6 weeks it will be ready for use.

Elderberry Wine.—The following recipe, from an unknown source, has been tried by an acquaintance, and proved good: 1 quart juice, 3 quarts water, 4 lbs. sugar, and 1 tablespoonful yeast to the gallon. Put it in a cask, in a cool situation, keeping the cask full. It soon ferments and discharges froth from the bunghole. When the fermentation is over, bung up or bottle. Boiling juice injures it.

Vegetable Soup.—Take a good sized chicken, or an equivalent piece of beef or mutton, cut it up and put it in water, rather more than enough to cover it, adding a tablespoonful of salt; boil until nearly tender, skim off the fat; add butter, salt, and pepper, and more water if necessary; then slice into the soup *ten* large potatoes, one small Swedish turnip, one carrot, two parsneps, (an onion and a few stalks of celery,) with two or three spoonfuls of rice; boil half an hour, or until tender. Before serving, add a spoonful or two of wheat flour stirred up with cold water. One or two spoonfuls of sweet cream greatly improves the flavor.



THE SOLDIER'S RETURN.

(Prepared and engraved expressly for the American Agriculturist.)

The Editor with his Young Readers.

Scenes like this in the picture, are now common in all parts of the loyal states. Youtsee the soldier has been wounded in the leg, and is now on furlough recovered that he can walk with his crutch. He is a sergeant in his regiment, and has got home to his family, where he is explaining to his parents, and to his wife and children, the scenes of the battle. The newspaper map is spread out upon the table, and with the stem of his pipe, he is showing "how fields were won." You see by the picture of General Scott up on the wall, and the cannon that little Robie is drawing upon the floor, that military education has been going on in the family during the father's absence. There stands a future soldier of the Republic. How he drinks in every word of his father's story, and enters into his sympathies! Will he not always love the dear old flag under which his father fought, and his heart thrill to the music of the Star Spangled Banner? What seeds of patriotism and hatred to treason are now being sown in young hearts all over the land! The wife is well pleased to see the head of the household home again, though he comes bearing the wounds of battle—scars that he must carry with him to his grave. She is proud to have borne a part in the sacrifices, by which the land of their fathers, or of their adoption, has been rescued from its perils.

One of the good things to come out of this war is the cementing of the nation into one homogeneous people. The miserable jealousy towards foreigners will be cured. Almost every European nationality is represented in our armies, and their blood has been poured out as freely as that of the older citizens of the Republic. All have stood together in the presence of a common danger, and have been made children of a common country, by a baptism of blood. The seal can never be effaced, and will never be forgotten.

Alas! for the homes to whom the soldier will never return. For them there is no tale of triumph for the fly they love, but loneliness and grief, for which there is no solace but in God, and in exalted patriotism.

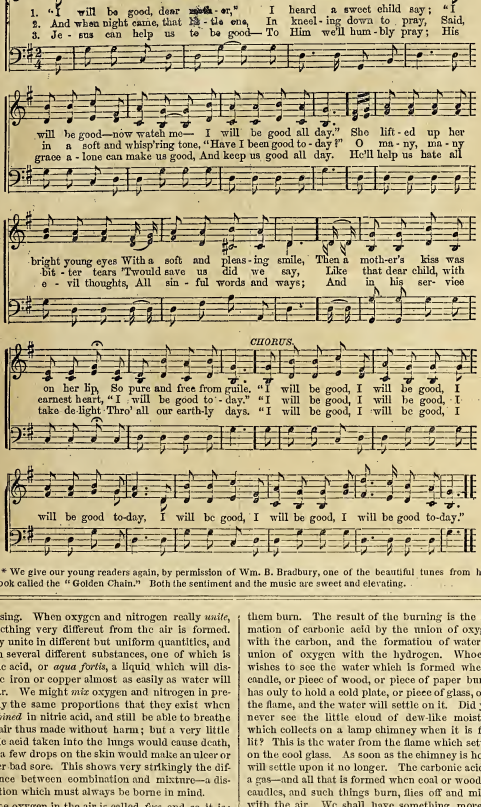
Something About Chemistry—III.

(Continued from page 184.)

Our young readers will remember that we told them, on page 183, about *Water*, that it was composed of two gaseous or air-like elements, oxygen and hydrogen; about the *Air*, which is a mixture of oxygen and nitrogen, chiefly; about the gas called *Carbonic acid*, which is formed when charcoal, or any thing which contains carbon, is burned in the air or in oxygen, and a little about Ammonia, composed of nitrogen and hydrogen. Now these substances, except the air, are compound bodies, the elements of which are united by *chemical affinity*. Affinity means the power which unites elements or compound bodies, so that two unlike substances form a new one unlike themselves, and in doing so, always combine in the same proportions. Thus when oxygen and hydrogen combine to form water, 8 parts (that may be 8 ounces, or 8 pounds, or any weight,) of oxygen unite with 1 part of hydrogen. When oxygen and carbon unite to form carbonic acid, 8 parts of oxygen unite with 12 parts of carbon, and so on. This is very different from mixing things together. We may mix salt and mustard, and oil and vinegar, and they make a salad dressing; but we know that each of the ingredients is still unchanged, for we taste each one in the mixture. In mixtures there may be more or less of either of the things mixed; but when things *unite* chemically, it requires a certain definite quantity of each. We told you that oxygen combined with iron, and formed iron rust, or oxide of iron Now in iron rust we perceive no oxygen, neither do we perceive any iron. 16 parts of iron united with 8 parts of oxygen; both the iron and the oxygen have disappeared, and we have red iron-rust, a new substance in all its relations. So it is with all chemical combinations, and this is the difference between mixed substances and compound bodies, whether they be solid, liquid, or gaseous.

The air, we have said, is composed of about one-fifth oxygen, and four-fifths nitrogen. This is a mixture, and the nitrogen softens the oxygen just as oil softens the vinegar and mustard in the salad

26—*Two to each Measure.* **I WILL BE GOOD, DEAR MOTHER.***



* We give our young readers again, by permission of Wm. B. Bradbury, one of the beautiful tunes from his book called the "Golden Chain." Both the sentiment and the music are sweet and elevating.

dressing. When oxygen and nitrogen really *unite*, something very different from the air is formed. They unite in different but uniform quantities, and form several different substances, one of which is nitric acid, or *aqua fortis*, a liquid which will dissolve iron or copper almost as easily as water will sugar. We might *mix* oxygen and nitrogen in precisely the same proportions that they exist when *combined* in nitric acid, and still be able to breathe the air thus made without harm; but a very little nitric acid taken into the lungs would cause death, and a few drops on the skin would make an ulcer or other bad sore. This shows very strikingly the difference between combination and mixture—a distinction which must always be borne in mind.

The oxygen in the air is called *free*, and so it is; that in water, and in iron-rust, and in carbonic acid, is *combined*, that is, united with other elements. When it is free, it enters into combination with other things generally, more easily than if it is in any combination. Now oxygen is the most abundant element; it is everywhere in the world—in the air, in the water, in the solid rocks, and in the soil. It is everywhere in a state of combination, except in the air, and will combine with every other element. Our own bodies, and those of the animals, and all plants, consist in great part of oxygen. It is therefore the most important, and is certainly the most interesting of all the elements. Wood, coal, tallow, oil, and all such things that we usually see burning, contain carbon, and all except anthracite coal and charcoal contain hydrogen also.

When any of these things burn, they combine with oxygen, and it is this very thing that makes them burn. The result of the burning is the formation of carbonic acid by the union of oxygen with the carbon, and the formation of water by union of oxygen with the hydrogen. Whoever wishes to see the water which is formed when a candle, or piece of wood, or piece of paper burns, has only to hold a cold plate, or piece of glass, over the flame, and the water will settle on it. Did you never see the little cloud of dew-like moisture which collects on a lamp chimney when it is first lit? This is the water from the flame which settles on the cool glass. As soon as the chimney is hot it will settle upon it no longer. The carbonic acid is a gas—and all that is formed when coal or wood, or candles, and such things burn, flies off and mixes with the air. We shall have something more to tell you next month about this carbonic acid gas.

The Tiger Lily and the Violet.

A correspondent of the *Agriculturist* sends the following story with a moral, to our young readers: "In the same bed with the lowly violets, and the modest lily of the valley, there grew a *Tiger Lily*, tall, showy, and soaring over these, as if despising them and glorying in its own large leaves and orange-colored spotted flowers. Some girls would notice *it* first of all, and say, "Isn't that handsome?" "Why no," Lizzy would answer, "I think the tiger lily is coarse and gaudy. I never put it in a bouquet." Her mother was pleased with her choice, and drew a lesson from it something like the following: The lily of the valley and the violets are emblems of *modest beauty*, (they always have been, as I could show from the best poets,) charming every beholder all the more because they are so unpretending, almost trying to hide away from gazing eyes. Genuine modesty is always beautiful; and its retiring manner never fails to be admired by the true and the good. "When unadorn'd, adorn'd the most."

The tiger lily may represent those who are pleased with vain display, and who fail to gain the admiration they court. Flaunting colors are very offensive to good taste; they indicate such qualities of mind as a correct judgment would never admire. The aspiring lily towered above the garden fence; a gust of wind broke off the stalk, and there it hung for weeks, an unsightly emblem of fallen pride. The violets and the lily of the valley nestled safely at its root, while the storms rolled harmlessly over them. (See Matt. 23: 12.) M.

Anagrams.

An Anagram is a certain transposition in the letters of any word or phrase, so as to make another phrase or word of pointed significance. They are sometimes quite interesting, and much amusement may be had in forming them. The following were received some time since:

Equestrianism—Quite near, Miss—[A very appropriate speech for a lady's companion in a horseback ride.]

Intemperate—Repeat "I ment." [Ah! yes; every intemperate man *ment* well enough.]

Degradation—To dread gain.

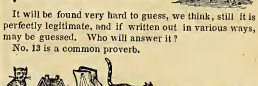
Incorrigibleness—Crinoline begs, Sir.

These from Miss MARY USHER.

Egotism—Miles go. *Atheist*—It hates. *Nectarines*—In ten acres. From RUFUS W. WEERS.

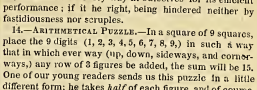
For the Guessers.

Rebusses.—We have here two Rebusses; one of them, No. 12, is a moral sentiment.



It will be found very hard to guess, we think, still it is perfectly legitimate, and if written out in various ways, may be guessed. Who will answer it?

No. 13 is a common proverb.



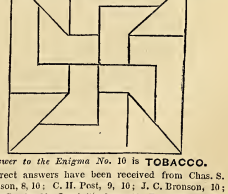
We think this will be found as easy to guess, as the other is hard. It conveys the lesson that, in whatever we do, we should in every way fit ourselves for its efficient performance; if it be right, being hindered neither by fastidiousness nor scruples.

14.—ARITHMETICAL PUZZLE.—In a square of 9 squares, place the 9 digits (1, 2, 3, 4, 5, 6, 7, 8, 9,) in such a way that in which ever way (up, down, sideways, and corner-ways,) any row of 3 figures be added, the sum will be 15. One of our young readers sends us this puzzle in a little different form; he takes *half* of each figure, and of course, the sum of each row is 7½ instead of 15. This, he thinks, entitles it to be called an "original" puzzle, but he is mistaken. The puzzle is an old one to the older boys and girls, though it is doubtless new to the "little shavers."

Answers to Problems.

Answer to the Rebus No. 8 is founded upon the text in Gal. vi: 7: "Whatsoever a man soweth that shall he also reap"—but it properly reads: What a man soweth that he reapeth.

Answer to the Block Puzzle No. 9 is given in the following cut. A somewhat different arrangement is admissable.



Answer to the Enigma No. 10 is **TOBACCO.**

Correct answers have been received from Chas. S. Stimpson, 8, 10; C. H. Post, 9, 10; J. C. Bronson, 10; Oliver Combs, 10; Jacob Stephens, 10; B. C. Atwood, 8; G. F. Sly, 8, 10; Abigail E. Downes, 9; J. H. Goodrich, 10.

1861	178,847	3,261,460	35,306	30,659	27,595	26,382

The foregoing tables exhibit the movements in Breadstuffs, both in New-York and the principal markets of the interior, so clearly as to call for no further explanation of that feature of the business.... The trade of the month in New-York has been on an extensive scale, the export demand for Flour and Grain having been active, though at lower prices. Recent intelligence from England was less encouraging, in reference to the prospects of the growing crops, especially of Wheat. Hence, export buyers have been more eager to purchase, and though some changes in the value of Flour have been unfavorable to sellers, there has been a noticeable improvement in prices of most kinds of Grain, particularly of Corn, and, sales, able for shipment. Within a few days receipts have been quite light, and the tendency of the market has been upward, though the extreme firmness in freights has operated as a check on this movement. The inquiry from the regular home trade is fair. There is an entire absence of speculation, which is generally regarded as a most gratifying symptom. While the news from Western Europe speaks gloomily of crop prospects, advices from most parts of our own country are very encouraging, and this circumstance indicates that on our own continent the fears of Great Britain and France will have to draw freely for a supply of cheap food, for another year, in order to make good the probable deficiencies in their own supplies. Altogether, this month closes quite cheeringly for our agriculturists, much more so, indeed, than was anticipated at its commencement, and we congratulate our readers on the very agreeable change.... A further important rise has taken place in Cotton, which has been in good demand throughout the month..... Provisions have arrived quite freely and have declined, with a moderate inquiry ..... HAY, Hops and Tobacco, have been in fair request at somewhat quotations ..... Seeds have moderately dealt in at uniform rates ..... Wool has been in more demand and prices have favored sellers. The new clip is now arriving rather freely at various points in the interior, and is bringing very full prices, when in good order and properly packed. Wool put up for market should be tagged and well tied up with twine of medium size, but not too coarse. In packing Wool for market, put it in bags such as are in use for sale in the city, the tare of which will be observed as three pounds. Such sacks are worth to the purchaser of wool nearly their cost for the purpose of re-sacking, whereas sheeting sacks, which are more commonly used, are worthless to re-sack in, and sheders will allow nothing for them. When there is an unusual number of buck fleeces in lots of Wool, dealers observe the same rules as to unwashed, viz.—one third off..... The Secretary of the Vermont Agricultural Society, Daniel Needham, in his annual report, states that, "reasoning from analogy, the price of wool during the next few years must be high,"—basing his views on the opinion that the cotton crop will not be planted as extensively as has been for some years past; and that the million of soldiers in the field will wear a third more clothing than they would in peaceful avocations.... The transactions in other agricultural products have been on a moderate scale. The table of prices show the changes and the present rates.

N. Y. Live Stock Markets.—THE CATTLE MARKETS have been well-supplied, the past month, the average receipts being 4,246 per week, or 200 less than the previous month. Prices have fluctuated somewhat, advancing 3c. May 20th, when 3,400 were on sale, and declining as much on the following week, when 5,366 beeves offered, again advancing ½c. with a light supply, remaining stationary the next week, and falling back ½c. at the last market, June 17th, when near 4,000 head were in market. The extra fat cattle sold at 8¾c.@9c. good fat steers 8½c., fair quality, 8c., and poor 7c.@7½c. Average of all sales 8c., and none left over.

Veal Calves.—Receipts are falling off rapidly, averaging only 760 per week since last report. They are ¼c. per lb. higher, the best bringing 6½c., fair veals 5c., and common 4c.@4½c. They sell readily.

Sheep and Lambs.—These are more abundant than last month, and sell briskly at former rates, or 4c.@4½c. 9 lb. live weight for fair to good sheep; 5c. for those extra fine. Lambs are plenty, selling at 7c.@7½c. per lb. live weight, or at an average of $4@$4½ per head. Receipts of both have averaged 7,722 per week.

Live Hogs.—Receipts are falling off with the advance of Summer. We have had but 9,951 per week since last writing, which are more than the demand warrants, and prices have continued to decline during the month, with some hogs left unsold each week. They are now worth 6c. for fair, 6½c. if corn fed, and 7c. for fat.

The Weather, during the past month has been variable, and the average temperature lower than usual at this season. The drouth prevailing when we closed our last number Fr. M., rain at night—12, clear, fine—13, hot, (86°) showers P. M.—14, clear, fine, N. E. rain storm at night—15, cloudy A. M., clear P. M.—16, 17, clear—18, cloudy—19, rain at night—20, clear, warm.

Rain Fall,—From the 15th of May, to the 15th of June, there were 8.86 inches of rain, which fell at 11 different times. The great rain of the 6th and 5th was much more coincidental in this vicinity, 5 1-5th inches falling in 24 hours.

Reports on Crops, June 10, 1862.

(*See General Remarks and Reports on Special Crops on page* 200, *and Notes to Crop Reporters on page* 197.)

EXPLANATIONS TO THE READER. (Full details are given on the Blank Forms furnished to Reporters.)

The First Column gives the Counties from which the reports come. In many cases the territory reported upon extends over adjacent counties, and the figures apply to a larger territory than the county named, but sometimes to single townships only.

The Second Column gives the number of persons in each county, the average of whose opinions are embraced in the single rows of figures, standing opposite in the same line. In several cases a whole County is represented by an officer of the Agricultural Society, who gives the summary of reports from assistants in each of the towns, as indicates that a large but indefinite number of persons joined in making the report.

The Third Column gives the names of the persons who received and distributed blanks, and collected and forwarded returns.

☞ *In all the reports the numeral* **10** *is taken as the standard for comparison,* thus:

Column A—10 means that the weather for a month previous to the date of the report was about as good as the average for other years, that is for growing crops and for general farm operations. Figures above or below **10** indicate the comparative propitiousness or unfavorableness of the weather.

Columns—B—E—H—In these **10** indicates that the amount of surface growing is about the same as *last year*. Each figure (or unit) above **10** means a tenth more of surface, and each unit below **10**, means one-tenth less. Thus, 5 means one-half of average surface—15 means one and a half—20 means double, and so on.

Columns C—F—I—N—P—S—In these columns **10** means that the average surface sown or planted or growing is about the same as the average for five years past. Each unit above or below **10** stands for an increase or decrease of one-tenth in the surface.

Columns D—G—K—M—O—R—T—U—V—In these columns **10** means that the *condition* and *prospect* on June 10th indicated an *average yield per acre*. Here also each unit above or below ten indicates the prospect of a yield a tenth above or a tenth below the average; thus, a half crop is indicated by 5—a double crop by **20**. Some report fruit prospects at **100** to **300**, meaning that the promise is for ten to thirty times the average.

Blanks left in a column indicate that little or none of the crop is grown, or that it is too early to report upon it, or that the reporter could not estimate satisfactorily to himself. No reports have been received from some whose names are in the list, and who furnished reports last month.—For comments and reports of other crops see page 200.

Circulation of the Agriculturist.

Beyond all doubt or controversy, the circulation of the American Agriculturist is to regulars subscribers, is many thousands greater than that of any other Agricultural or Horticultural Journal in the World, no matter what its character, or time or place of issue. The publisher is ready at all times to substantiate this statement by comparing books.

New and Splendid Varieties of Strawberries.
Empress Eugenie, Margarite, Prince Frederick William, Victory, and Osband's Mammoth.
The two last are American Seedlings. Fruit of immense size. The other three are the prize varieties of Europe for 1861. Fruit of extraordinary size, weighing from one to two ounces each. The above at $1.00 per dozen, or the five, one dozen each, for $5.00.
The following new and fine varieties La Constante, Wizard of the North, Wonderful, Oscar, Duc de Brabant, Prince of Wales, Honneur de Bellepize, Filbert Pine, Crimson Queen, Prince Imperial, Surpass Triomphe, Deptford White, and Duc de Malakoff, at $3.00 per dozen, a selection of six for $4.00, or the thirteen varieties for $7.00.
La Constante can be furnished by the hundred for $4.00. This magnificent berry, after two years trial, has proved to be of great value as a market berry. Fruit very large, fine color, and very productive. A special prize was awarded this variety at the exhibition in Boston last year.
Triomphe de Gand, Bartlett, Downer's Prolific, Jenny Lind, True Chili, and Alpine, at $2.50 per hundred, or $20.00 per thousand. The Downer's Prolific is a fine market berry; it is more productive than the Wilson. Fruit large and a beautiful scarlet color.
Great Austin Shaker Seedling, 30 plants $1.00; $2 per 100; $15.00 per 1000. Not less than one dozen sold of any variety. All orders addressed to
WM. S. CARPENTER, 329 Greenwich-st., N. Y.

SUPERIOR STRAWBERRY PLANTS. $3
Grown with special care, and warranted to give satisfaction, or money will be refunded. Triomphe de Gand, $3.50; the Great Austin or Shaker, $2; Wilson's $1 per 100. Great reduction in price when one or more thousands are taken.
J. C. THOMPSON, Tompkinsville, Staten Island, N. Y.

MME. DEMOREST'S MIRROR OF FASHIONS.—Splendid improvements, elegant Fashion Plates, fine Engravings, the latest Information, three full-sized Patterns, elegantly illustrated, and Braid Work and Embroidery; the largest and best Fashion Magazine in the world. Published quarterly at 472 Broadway, and sold everywhere at 25 cents. Yearly $1, with the privilege of selecting 50 cents' worth of plain Patterns extra, as a Premium. Summer No. now ready.

Great Austin Shaker Strawberry.
The berries of this remarkable variety are much larger than any other Strawberry grown in this country. It produces enormous crops, and the fruit is very attractive, being of fine scarlet color. The Austin was exhibited at the office of the American Agriculturist last year, weighing one ounce. Nearly 1000 boxes were sent from Watervliet last year, a distance of 150 miles, and sold to Taylor, corner Broadway and Franklin-sts., New-York, for 50 cts. per quart, proving the Austin to be one of the most profitable market berries in cultivation. Our stock of plants is very large and fine, at the following rates: 50 plants $1; per hundred $2.00; per thousand $15.00. We commence delivery plants on the first of August, in rotation as ordered. Address either
CHAUNCEY MILLER, Albany, N. Y., Shaker Trustee, or
WM. S. CARPENTER, 329 Greenwich-st., New-York.

CARD.
DAVID LANDRETH & SON,
PHILADELPHIA,
PROPRIETORS OF BLOOMSDALE,
issued on the 1st inst. their
Turnip Seed Circular,
for the present year. It is addressed
EXCLUSIVELY TO DEALERS IN SEEDS,
and all such, who desire a copy, whether Druggist, Country Merchant, or Seedsman, will be supplied by mail, on the receipt of address, written on a letter envelope, with one cent stamp affixed.
The attention of Dealers is specially requested to the following paragraphs in the Circular referred to:—
"At no previous time has the Peninsula been greater for full supplies of Seeds. The late mild Winter was propitious for the preservation of all roots designed for Seeding, and each acre of our grounds (nearly 400 in extent) gives promise of a prolific harvest: under these favorable circumstances we feel disposed to admit our customers to a share of our good fortune, and shall accordingly reduce the prices of most leading articles."
Inasmuch as the true interest of our customers, Dealers in Seeds, and ourselves, is closely allied, we shall abstain from soliciting the orders of consumers resident near any of our wholesale costumers, leaving to them the undisturbed retail trade." DAVID LANDRETH & SON,
Nos. 21 & 23 South Sixth-st., Philadelphia, Pa.

First Premium at 20 National and State Fairs.
THE ONLY RELIABLE EVAPORATOR!

Cook's Sugar Evaporator.
BLYMYERS, BATES & DAY, Manufacturers, MANSFIELD, O.

$256. Premiums amounting to $256 **$256.**
Were awarded for the best 5 gallon samples of Sorgho Sugar of not less than 30 lbs. each, at
The Illinois State Sorgho Convention.....January, 1862.
The Ohio do. do. 1862.
The Michigan do. do. .....April, 1862.
These Conventions were very largely attended by farmers, and almost every Mill and Evaporator in the country was represented at one or the other. OVER THIRTY SAMPLES OF SUGAR WERE EXHIBITED. The STRIKING FACT is, who took the first premium at the Illinois Convention but about ONE YEAR'S SUGAR! On inquiry it was ascertained that all THESE SAMPLES WERE MADE ON THE COOK EVAPORATOR; thus fully sustaining our claim that it is the ONLY SUCCESSFUL SORGHO SUGAR-MAKER. While we have established the position that Sugar could be made, other Evaporator men, whose contrivances would make NOTHING BUT POOR SYRUP, have so industriously labored to show that Sugar could NOT be made, and thus for the sale of their inferior machines, have retarded the onward progress of the Sorgho manie. But while the Cook Evaporator

A Ton of Sugar.

Makes a splendid Sugar, it also
Makes a beautiful golden, honey-like Syrup,
Makes more in a day, and
Makes it with less fuel than any other process of boiling.
It is a better Sugar machine than any other Evaporator, constructed of equally good material, made with equal care, and accomplishing anything like the same amount of work.
OVER 2500 are in use, and not one case ever returned.
Do not throw away your money and crops upon common kettles, pans, or poor and unreliable Evaporators; buy only that which has stood the test of years in almost every part of the United States.
Send for a pamphlet containing full instructions, with testimonials and price list.

A Ton of Sugar.

INGERSOLL'S IMPROVED
HORSE AND HAND POWER
HAY AND COTTON PRESSES.

These machines have been tested in the most thorough manner throughout this and foreign countries to the number of over 1,200.
The HORSE POWER is worked by either wheel or capstan, and is the most complete, compact and powerful ever made. We invite those wanting such machines, to write for a catalogue containing full information, with cuts, prices, etc., or call and examine personally.
Orders promptly attended to, by addressing
INGERSOLL & DOUGHERTY, Greenpoint, Kings Co., L. I.

THE HYDROPULT,
THE GREAT PATENT OF THE AGE.
The most available Fire and Garden Engine in the world. See American Agriculturist for March and June, 1861. Price $12.00. Liberal discount to agents. Please call and examine it at 254 Broadway, or send for Circular.

JOHN P. ADRIANCE,
Manufacturer and Proprietor,
Manufactory, Po'keepsie, N. Y.
Warehouse 165 Greenwich-st., New-York.

EXCELSIOR
BURR STONE MILLS.
(FOR FARMERS AND MILLERS.)
AND
ANTI-FRICTION
HORSE POWERS.

Took TEN FIRST PREMIUMS at WESTERN STATE FAIRS last year, and are justly considered superior to all others.
The Mill may be driven by *horse, water, or steam power*, does its work as well as the last stone mills in milling establishments, and requires but *one-half the power* to drive the largest sizes. They are very compact, perfectly simple, and for farm use will last *thirty years*, and cost *nothing* for repairs.

THE HORSE-POWER,
Has proved itself to be the best ever invented. The friction is reduced by IRON BALLS, so arranged in all the bearings, that the whole weight of the castings runs upon them. THREE POUNDS DRAUGHT, at the end of a treadfoot lever, will keep the power in motion! thus permitting the ENTIRE STRENGTH of the horses to be used on the machine to be driven. ONE HORSE will do as much work on this power, as two on the endless Chain Power. IT IS PORTABLE, and may be used IN THE FIELD as well as in the house. More than TWENTY-FIVE PER CENT of horse flesh is saved over ANY OTHER POWER IN USE. It is simple in construction, and not liable to get out of order.

Price of Power for 1 to 4 horses $125
Price of Power for 1 to 8 horses 175

THE SIZE POWER WILL DRIVE ANY THRESHING MACHINE. EVERY MACHINE IS GUARANTEED TO GIVE SATISFACTION, OR THE MONEY WILL BE REFUNDED.

We have completed an arrangement with the Western Transportation Co., by which they agree to deliver our Mills and Powers at PORTS ON LAKE ERIE AT 25 CTS. PER 100 lbs.; MILWAUKEE, CHICAGO, AND INTERMEDIATE PORTS AT 30C.; SHEBOYGAN AND GREEN BAY AT 35C., and to TWO RIVERS, MANITOWOC, AND PORT WASHINGTON, WIS., AT 40C. PER 100 lbs.
Liberal discount to agents. State, County, and Shop Rights for sale. For testimonials and farther information see May number of this paper, or send stamp for Illustrated Circulars to BENNET BROTHERS,
42 and 44 Greene-st., New-York.

A RELIABLE AGENCY
FOR PURCHASING
ARTICLES OF MERCHANDISE,
IMPLEMENTS FOR THE FARM, GARDEN, AND HOUSEHOLD.

Fruit and Ornamental Trees, and Plants.

Special attention will also be given to procuring Sewing Machines; Pianos and other Musical Instruments; Philosophical and Astronomical Apparatus; Books for Schools and Colleges, and School Furniture.

STRAWBERRIES.

We shall be ready the last of August to furnish the following choice varieties of Strawberries:

Triomphe de Gand, 30c. per doz., $1.50 per 100, $10 per 1000, $25 for 2500, $38 for 3500, and $50 for 10,000.

Bartlett, Downer's Prolific, Fillmore, and True Chili, 50c. per doz., $1.50 per 100, $10 per 1000, $20 for 2500.

Austin Seedling, $1 for 30, $3 per 100, and $15 per 1000.

Trollope's Victoria, Vicomtesse Hericart, Hooker, Jenny Lind, Wilson's Albany, and other standard sorts, at $1 per 100. Also the following new varieties:

La Constante, Crimson Queen, May Queen, Duc de Malakoff, Duc de Brabant, Filbert Pine, Georgia Mammoth, Prince Imperial, Bonte St. Julien, Reine Hortense, Honneur de Belgique, Dodford's Seedling, Hetton Pine (large scarlet), at $1 per dozen, or a selection of six varieties, one doz. each, $4—a few hundred of La Constante, at $4 per 100. Also sent by mail at $1.25 per doz.

A few dozen of the Empress Eugenie, Princess Frederick William, and Margarite, the prize berries of Europe for 1861, which will be furnished in pots at $3 per dozen.

Also, Triomphe de Gand and Bartlett, extra fine, struck in pots, $2 per 100, or with the pots $3.50 per 100. Austin Seedling, in pots, $1 per doz., $4 per 100.

For $3 I will send by mail, post-paid, 30 Austin Seedling, or 25 Triomphe de Gand or Bartlett.

The subscriber is agent for the Nurseries of PARSONS & CO., and sole Agent for the sale of Fuller's New Seedling Strawberries. Prices and description next month.

The Postage on the Agriculturist is positively only Six Cents a Year.

We hear that several Post Masters are charging 12, 18, 36, and even 72 cents a year on the *Agriculturist*. This is wrong. The law expressly says that a Periodical issued at stated periods, and not weighing over 3 ounces avoirdupois, shall be charged *one cent* per number, and only *half* this sum if paid quarterly in advance. The paper for the *Agriculturist* is purposely manufactured so that it shall weigh a little *less than three ounces*. We would add an occasional extra page for more advertising room, could we do so without increasing the postage to our subscribers. The Postmaster General has several times decided that postage on the *Agriculturist* is only six cents a year. See one of these decisions on page 96, volume XVII. There has been no change in the law or in the weight of the paper since. The paper must be weighed *dry*, and *without the wrapper*. Subscribers will please promptly inform us of any future over charge.

Mail-Lost Numbers Supplied.

It is hard for the Publisher to alone bear all the losses arising from the carelessness or over-sight of any of the 18,000 Postmasters and carriers who have the handling of the *Agriculturist* between the office and the subscribers. But since Uncle Samuel monopolizes the carrying business, and won't stand any losses, and we can't compel him to, we shall cheerfully send a second copy of any number when the first one mailed fails to reach its proper destination, on being notified of the fact. We suspect from the reports, that one of the packages sent to Providence, R. I., last month, has not got there yet. Let us know who are without that Number.

CLUBS

Can at any time be increased, by remitting for each addition, the price paid by the original members—provided the subscriptions all date back to the same starting point. The back numbers will of course be sent to added names.

An American Exhibition OF Pumpkins, Squashes, and Ornamental Gourds.

There will be a Public Exhibition of **Pumpkins, Squashes, and Ornamental Gourds,** at the office of the *American Agriculturist*, 41 Park Row, New York City, opening on Wednesday, Nov. 5th, 1862, at which the following prizes will be paid by the Publisher, upon the official award of competent Committees.

CASH PREMIUMS.

I. For the *Heaviest* Pumpkin or Squash...$20.00
II. For the 2nd do. do.....10.00
III. For the 3d do. do.....5.00
IV. For the Best do. do. for cooking..10.00
V. For the 2nd Best do. do. do.....5.00
VI. For the largest yield on a single Vine.*...10.00
VII. For the 2nd do. do. *.....5.00
VIII. For the largest and finest collection of Fancy or Ornamental Gourds*.....10.00
IX. For the 2nd do. do. *.....5.00

* All to be grown by one person and to be accompanied by a verified statement from the grower, and two disinterested persons who assist in gathering the specimens.

Note 1.—The specimens receiving the Prizes will remain on Public Exhibition at the pleasure of the Publisher who offers the prizes. The other specimens will be subject to the order of the exhibitors, or they will be sold at Auction or otherwise disposed of, for their benefit.

Note 2.—All Exhibitors must notify us of their intentions by Oct. 10th, and deliver specimens for competition on or before Nov. 3d. Specimens to be delivered free of charge.

American Agriculturist in German.

The AMERICAN AGRICULTURIST is published in both the English and German Languages. Both Editions are of the same size, and contain, as nearly as possible, the same Articles and Illustrations. The German Edition is furnished at the same rates as the English, singly or in clubs. A club may be part English, and part German.

Bound Volumes—Binding—Covers.

We have complete sets of Vols. 16, 17, 18, 19, and 20, both unbound, and bound separately in neat covers with gilt lettered backs.

PRICES AT THE OFFICE.

Volumes 16, 17, 18, 19, and 20, *unbound*.....$1.00 each.
Volumes 16, 17, 18, 19, and 20, *bound*.....$1.50 each.

PRICES WHEN SENT POST-PAID BY MAIL.

(They can not go unpaid.)

Volumes 16, 17, 18, 19, or 20, *unbound*.....$1.12 each.
Volumes 16, 17, 18, 19, or 20, *bound*.....$2.00 each.

BINDING.—Sets of numbers brought to the office will be bound up neatly (in our regular style of binding the *Agriculturist*) for 50 cents a volume.

PREPARED COVERS.—Covers for binding, neatly made, with title, etc., gilt upon the back, ready for the insertion of the sheets by any bookbinder can be furnished for Vols.15, to 20 inclusive, at 25 cents per cover. *Covers can not go by mail.*

EXTRA PREMIUMS

For June and July, 1862.

STRAWBERRY PLANTS

Sent Free by Mail.

The Strawberry premiums offered previous to May 10th seemed to give general satisfaction. We sent out many thousands of plants to almost every part of the country, all of which, we trust, are growing finely. (The plants were growing too rapidly to be forwarded by mail *after* the advertised time, May 10, and a few sent after that date to late applicants, perhaps did not reach them in so good order as if sent earlier.) In response to many requests, we continue the Strawberry Premiums, the plants to be sent out the latter part of August or the first of September, according to the season, and the locality for which they are designed. We are propagating plants in our grounds, and have engaged a supply from elsewhere. At present, we will only propose the **Triomphe de Gand,** and **Hartlett,** as hitherto offered; but should the present season develop superior qualities in other new varieties, an equivalent of the new selections will be given. A list of such sorts (pe haps several) as we can furnish will be published in the *August Agriculturist*. Plants set out in August, or early in September, will multiply somewhat this year, and bear next Spring.

CONDITIONS;

PREMIUM I. To any person forwarding, (now or before August 1st), ONE subscriber to the *American Agriculturist*, at $1 a-year, we will present (if desired **Ten Plants** of the **Triomphe de Gand Strawberry,** or an equivalent selection from other sorts that we may have, to be sold from in August or September, according to their destination, as above stated.

PREMIUM II. For TWO subscribers, the same as Premium I, but **Twenty-five Plants**, or their equivalent, in other new choice varieties, instead of ten.

PREMIUM III. For THREE OR MORE subscribers, the same as Premium I, but **Fifteen Plants** or their equivalent in other varieties, for **each name.**

Premiums for Northern Grown Cotton.

One Hundred Dollars are offered for the best five specimens of cotton grown above latitudes 38° and 40°, the present year, as follows: For 10 lbs., (unginned,) grown north of latitude 40°, 1st prem., $50; 2d $20; 3d $10. For 10 lbs., (unginned,) grown north of latitude 38° and south of 40°, 1st prem., $25; 2d $15; 3d $10. The samples on which premiums shall have been awarded, will be retained on our exhibition tables for the Inspection of the public. All others will be subject to the direction of the exhibitors, at the close of the Exhibition. For particulars see February number of *American Agriculturist*, page 64.

American Agriculturist.

For the Farm, Garden, and Household.

A THOROUGH-GOING, RELIABLE, and PRACTICAL Journal, devoted to the different departments of SOIL CULTURE—such as growing FIELD CROPS; ORCHARD and GARDEN FRUITS; GARDEN VEGETABLES and FLOWERS; TREES, PLANTS, and FLOWERS for the LAWN or YARD; care of DOMESTIC ANIMALS, &c., &c., and to HOUSEHOLD LABORS. It has also an interesting and instructive department for CHILDREN and YOUTH.

A full CALENDAR OF OPERATIONS every month.

THREE to FOUR HUNDRED, or more, ILLUSTRATIVE ENGRAVINGS appear in each volume.

Over TWELVE HUNDRED PLAIN, PRACTICAL, instructive articles and useful items, are given every year.

The Editors and Contributors are all PRACTICAL WORKING FARMERS.

The teachings of the AGRICULTURIST *are confined to no State or Territory, but are adapted to the wants of all sections of the country—it is, as its name indicates, for the whole* AMERICAN CONTINENT.

TERMS—INVARIABLY IN ADVANCE.

(For either the English or German Edition.)

One copy, one year.....$1 00
Six copies, one year.....5 00
Ten or more copies one year.....80 cents each.

☞ Add to the above rates: Postage to Canada, 6 cents; to England and France, 24 cents; to Germany, 36 cents.

Postage anywhere in the United States and Territories must be paid by the subscriber, and is *only six cents a year*, if paid in advance at the office where received.

All business and other communications should be addressed to the Editor and Proprietor,

ORANGE JUDD, 41 Park-Row, New York City.

AMERICAN AGRICULTURIST,

FOR THE

Farm, Garden, and Household.

"AGRICULTURE IS THE MOST HEALTHFUL, MOST USEFUL, AND MOST NOBLE EMPLOYMENT OF MAN."—WASHINGTON.

ORANGE JUDD, A.M., EDITOR AND PROPRIETOR.
Office, 41 Park Row, (Times Buildings.)

ESTABLISHED IN 1842.
Published both in English and German.

$1.00 PER ANNUM, IN ADVANCE.
SINGLE NUMBER, 10 CENTS.
For Contents, Terms, etc., see page 256.

VOLUME XXI—No. 8. NEW-YORK, AUGUST, 1862. NEW SERIES—No. 187.

Entered according to act of Congress in the year 1862, by ORANGE JUDD, in the Clerk's Office of the District Court of the United States for the Southern District of New-York.

☞ Other Journals are invited to copy desirable articles freely, if each article be credited to *American Agriculturist.*

August.

"Thrice happy, he who on the sunless side
Of a romantic mountain, forest-crowned,
Beneath the whole collected shade reclines;
Or in the gelid caverns, woodbine wrought,
And fresh bedewed with ever-spouting streams,
Sits coolly calm, while all the world without,
Unsatisfied and sick, tosses in noon;—
Emblem instructive of the virtuous man,
Who keeps his tempered mind serene and pure,
And every passion aptly harmonized,
Amid a jarring world with vice inflamed."—THOMSON.

These forest-crowned hill-tops and mountains, where it is really cool in these glowing Summer days, are more easily found in the poet's imagination, than in nature. The air is so sweltering that we find it difficult to believe that they exist at all. Clothing is a burden, even the fine linen of snowy whiteness reflecting every ray of the sun. The air has a furnace breath, and makes every living thing swelter. Even the inanimate world cries out under the infliction. The trees stand with drooping leaves in the breathless air, the grass loses its fresh green look, the flowers hang their heads or close their petals, big drops stand on the water pitcher as if uttering its tearful protest against the torrid heat. The very thought of ice sends a thrill through the blood like the rapture of song. We do not doubt that there are cool places in the world, but they are not very easily reached. In the City every thing is baked. Put your hand upon the brick wall, and you can hardly endure the touch. There is hardly a dry thread in your shirt, by the time you are fairly seated in your office. The easiest manual labor is a burden. Mental effort is the very punishment of Sisyphus. Every thought is heavy as a bowlder, and if you attempt to roll it into place, it comes back again with a rebound. You find yourself doubting if your brains are not baked, like every thing around you.

In the country it is not quite so bad, for there is sometimes a breeze there, and dew gathers on the grass at night fall. But in the broad glare of the sun, every thing wilts, and all creatures flee to the shade. Yet this bright sunshine so characteristic of our Summers, and so uncomfortable while it lasts, has its advantages. We would not willingly exchange it for the milder skies of Britain, with her greener fields, and boundless turnip crops. Our sunshine is as golden to the farmer as to the poet's vision. To him it is a real Midas, changing every thing it touches into gold. These few weeks of extreme heat give us many of the advantages of the tropics, without their evils. Our great cereal crop is of southern origin, and is only made a success by the torrid heats of July and August. It luxuriates in the sunshine, when the thermometer points to a hundred, and bears drouth better than any other of our crops. It is often a failure in the northern belt, where it is cultivated, from the want of a single week of hot weather. It may droop at midday, but it grows apace at night, when heat drives sleep from the farmer's pillow. These fierce burning days, then, mean great crops of Indian corn. The bright rays are transmuted into the golden grain, and when sold become the real gold in the farmer's purse. Our country is the Paradise of this plant, and one can hardly comprehend the magnitude of the corn crop. It is easy to write a thousand millions of bushels, but difficult to take in the conception of so vast a bulk. It is nearly a bushel for every inhabitant of the globe, and thirty bushels to every one of our own population. What countless stores of food for man and beast are showered upon us in the sunlight! The crop this year, well sold, would pay the year's expenses for our great war.

These hot days also mean melons, one of Nature's bountiful provisions to slake the thirst of parched lips, and cool the fevered blood. We see them luxuriating in the sands of Long Island and the Jerseys, and even far up the valleys of the Connecticut and the Hudson, as juicy and high flavored as in the Carolinas. In some localities they require a little help from the gardener's art, but in this latitude they are as sure as Indian corn. They are grown very extensively, and could be produced in any quantity were there a market for them. We see them in huge piles on the boats and wharves, and at the green-grocer's. They are sent far inland to the cities and rural villages, wherever the sales will pay. They form a much more healthful dessert than pies and are quite as well relished.

In these tropical days tomatoes are a possibility. They have become a popular dish within the last twenty years, and are now almost as widely known as the cucumber. They propagate themselves even more readily, and flourish as a weed where they have once been introduced, if they are not carefully gathered in the fall. Though not generally relished at first, most people become very fond of them after a short acquaintance, so that they even supplant the cucumber. They are a much more healthful and nutritious dish, and what the doctors lose the people will gain, when it entirely displaces its rival. Though not so great an acquisition as its congener, the potato, it came much more rapidly into general use, and is an article of considerable commercial importance. There is always a large demand for tomatoes in their season, which covers about two months, but which may be almost indefinitely extended by putting up the fruit in cans and jars.

A large part of the favorites of our gardens—corn and tomatoes, squashes and melons, egg plant and okra, peppers and sweet potatoes—are natives of the tropics. They have been introduced among us without any concerted action, and stand upon their own merits. Some of them require a little more skill and care in their cultivation than indigenous plants, but they are likely to grow in popular esteem as horticulture becomes every year more generally appreciated. We have no reason to believe that these plants exhaust the list of garden vegetables from the south that may be acclimated in the north. The happy accidents that have brought these to our notice will gradually introduce others. Every such acquisition is an addition to the comfort of families, and to the national wealth. Health and refinement are both promoted by the variety of food which the family consumes.

Baron Liebig measures the civilization of a people by the quantity of soap they consume. A still better test is the variety of fruits and vegetables they produce in their gardens. The tropical man with his everlasting rice and plantains, and the Esquimaux with their seal and blubber, are rather low types of humanity. Between these extremes we find a greater variety of food and a higher degree of civilization. But this is not purely a matter of climate. Upon the same line of latitude in our country, we find very different tables spread for human repasts, even among farmers. In one home you may find almost every thing that will grow in the climate, taking its turn upon the table in its season. The strawberries come in May and the apples go out with April of the following year, a constant succession of good things, that make the meal hours pleasant reunions of the whole family. In another you shall find the everlasting hog and hominy in some of its forms every day of the year, or potatoes and salt junk the prominent features at dinner for six days in the week. The vegetable garden is regarded as a nuisance and the fruit yard and orchard are unknown. "Familiarity breeds contempt" with things, if not with persons, and the same dish at dinner, after a while, makes a family morose, and unsocial. A new dish is a nest of new ideas. A smile lights every countenance and the tongue is unloosed. We forget dog-days in gumbo soup and chicken salad, and other such-like things. And no idea is more erroneous, than that it is wrong to seek after enjoyment in eating. We ought to enjoy our food, and if we cultivate simple tastes, the greater variety we have, the better,

Calendar of Operations for August, 1862.

[A glance over notes like the following will generally call to mind some piece of work that would otherwise be forgotten or neglected. The remarks are more especially adapted to places between 38° to 45°; but will be equally applicable further North and South, by allowing for latitude.]

Farm.

The work for this month, although arduous, is less driving and more diversified than that for the one just closed. Harvesting and haying are nearly completed, and what remains to be done should be urged forward with sufficient promptness to save the loss by shelling, which attends harvesting grain that has become too ripe, and the loss to hay by too much drying. This done, the attention may then be profitably occupied until time for Fall sowing, with making improvements, such as draining, getting out muck, repairing buildings, and implements, working roads, etc. Little things postponed in the hurry of harvest, should be attended to at the earliest opportunity. Their increase is liable to equal that of spiders and compound interest. Now is a good time also to look up additions to your stock, if more is wanted, or if there is room for improvement in breed. Judicious investments of this kind are quite sure to pay. Good stock is the best *bank* in which to "deposit" the surplus products of the farm. So if possible keep all your farm will support well.

Barns, granaries, etc., should often be examined to see that air is let in, and rain, dampness, vermin, fowls, etc., kept out. Bear in mind also the preservative properties of paint. See that all store animals may have plenty of light, as well as air. Both are essential to their health.

Butter—See that everything used in butter-making is scrupulously clean. It pays butter-makers to be particular to do all of their work thoroughly and perfectly as possible. Wash out every particle of butter-milk from the butter, if to be kept for any length of time, and keep the butter as cool as circumstances will permit.

Cattle should not be allowed to loose flesh between this and winter. It is cheaper to keep them in flesh now than to regain it in winter. Milch cows especially need generous fare. Give them a dessert from the sailing's and/or of bran and shorts wet up. They will not object to an occasional cabbage, and cabbages are excellent for them and for milk.

Corn will soon furnish a delicious addition to table vegetables in the shape of green corn, which if well cooked and thoroughly masticated is wholesome. If wanted for future use shave from the cob and dry for succotash, etc. (See item in basket.) We have seen whole ears preserved in salt brine which had a very inviting appearance on the early warm days of the following Spring. Keep the weeds out of the corn as you would robbers from your hen-roost, but guard against mutilating and displacing the roots of the corn by deep tillage.

Draining should be attended to now, if needed and practicable. Be content with nothing short of good underdraining, as this will not carry off one of the great elements of the farmer's wealth—manure.

Fallows, or "Summer Fallows" should be looked to. Let them not become nurseries of foul weeds. You can pull by hand one weed now cheaper than you can plow up the hundreds it may produce next year.

Fences are becoming less used, as the laws restraining the roaming at large of stock are improved, perfected, and enforced. But wherever needed, let them be substantially built, and kept in good repair. "Whatever is worth doing at all is worth doing *well*." Do not let them harbor a Pandora's box of weeds.

Gleaning usually pays, but how well of course depends upon the thoroughness of the raking.

Grain, especially that which can not be put under good shelter, should be thrashed at the earliest convenience. Make thorough work of cleaning, whether for seed or market. It is usually better to sell as soon as the market is fairly fixed. Use all that can be turned to account in fattening stock.

Hay—Cut any remaining. Gather coarse wild grasses for bedding for animals. Secure salt marsh hay and sedge, during the low tides of August, and remove to safe quarters. Surround stacks with good fences to keep cattle from wasting.

Horses, repay humane and careful treatment. Give them the luxury of shade and air, when practicable, during the heat of day. Use nets, or try a wash made by steeping walnut leaves, to keep off the tormenting flies. They will enjoy freedom in the pasture, nights.

Insurance—Good insurance companies and lightning rods have saved many a man from sudden destitution. It is usually advisable to invest a percentage judiciously in this direction.

Irrigation—Consider well, and try experiments. The subject is of momentous importance to farmers individually and to the country at large. (See articles on pages 193 and 209, July *Agriculturist*.)

Manures—Purify the atmosphere around house, sheds, barn-yard and barn, by transferring all manures collectable thereabout to the mowing lands, or compost heaps. Gather unripe weeds, refuse straw, etc., to absorb liquid manures in the hog pen and cattle yards, and remove and renew often. The health of your animals and the wealth of your acres will be promoted thereby.

Meadows—Remove bushes, rocks, and other obstructions from mowing lands. Top dress new mown lands with fine compost, to protect the roots from scorching, and quicken the young growth. Keep stock from mowing until the grass is well started, and do not allow it to be eaten off very close.

Millet or Hungarian Grass—Cut before the seed ripens, if intended for hay. Feed sparingly.

Oats—The harvest is at hand. Cure the straw carefully: it is valuable for feeding.

Pastures—Occasionally scatter cattle-droppings with a maul. Allow no weeds to ripen seed. Sow salt about their roots, to attract the cattle and sheep, and prevent the young shoots springing up. Suffer no fields to be fed too closely.

Potatoes—It is claimed that rot may be arrested by promptly removing affected tops or haulm. In place of early harvested potatoes, quick-growing turnips or late cabbages may be grown.

Poultry may be benefitted by gleaning the grain fields after harvest. If confined to the yard, give plenty of water, gravel, lime, and occasionally a little animal food, to stimulate them to lay. Fatten chickens and ducks for market early; it takes less grain in warm weather, and the prices are more remunerative.

Root Crops—Thin out where too thick. Keep the ground light and free from weeds by frequent use of the cultivator and hoe.

Rye—Harvest any remaining. Glean the fields with the horse rake, and thresh out the scatterings for grinding and feeding to hogs. Select the best growth for seed, and thresh with a flail. Rye flour as sponge for bread, rises quicker than wheat flour.

Sheep—Separate rams from the ewes and give the lambs a rich pasture by themselves or with the yearlings. Keep a few older sheep with them as leaders of the flock. Examine the udders of ewes while weaning their lambs, and draw the milk occasionally if necessary to prevent their becoming caked. Salt freely, and apply tar to their noses to repel the fly.

Swine—Keep them growing by liberal feeding. Commence fattening. Early pork is usually in demand, and it costs less to make it. Feed with green food frequently. Unthrashed pea vines are well relished, and are wholesome diet. Corn is fed, try boiling, or at least soaking.

Timber cut at this season is believed to be most durable. Prepare any needed for fencing or building next season. Strip off bark as soon as cut.

Timothy sown late this month, will ordinarily give a good growth next season. If sown with winter grain, leave it until next month or the following Spring. Use from eight to twelve quarts of seed per acre, according to circumstances.

Turnips—Strap leaf, or flat varieties, may be sown, among corn, after early potatoes or on other unoccupied ground. (See article on p. 243.)

Winter Grain—Prepare grounds, to be sown late this, or early next month. It will succeed on sod ground, but preference is generally given to cultivate it after fallow, oats, or an early hoed crop.

Orchard and Nursery.

Sparse crops of fruit in many parts of the country during several years past, had so checked the ardor of enthusiastic fruit-growers that too many of them have neglected the care of old orchards or failed to plant new ones. Those who have given proper attention in these respects, are now fully repaid, and in the abundant crops this year, they feel encouraged to believe that fruit trees may still flourish and bear, and yield, as now, a remunerative harvest.

Gathering the early fruit in the orchard, and budding in the nursery, will be the chief labors of August. The ripening apples and pears must be secured or they are lost. Where a good market is at hand, the fruit should be carefully picked and sold. If there is no market, gather and make into cider, dry or put up in bottles for winter use. In gathering the fruit, great pains should be taken not to injure the trees. Heavy boots are apt to start the bark on the branches, if worn when climbing about in the trees. Thrashing the trees with poles is an abominable practice, beating off the fruit spurs with the fruit. Some of the late fruit trees will need to have their overloaded branches braced or tied up, or what is better, a portion of the fruit removed, that the remainder may be finer, the tree not overtaxed, and the branches saved from splitting down beneath their burdens.

If the trees have not been pruned, they may well receive a trimming now, where it can be done without injury to the fruit. In the nursery the knife may be used to good advantage upon small trees. The work of budding the nursery seedlings should proceed, and it is better to bud than to graft small trees, unless they are allowed to attain a sufficient size to graft in the branches. Most people, however, prefer to buy "grafted trees" as they are called, hence the stocks of one and two years old should be budded this month. See full directions in July *Agriculturist*. Round off any stocks budded last season and not already cut off close to the bud.

If borers have been permitted to hatch out and penetrate the bark of peach, apple or quince trees, they may be found and cut out before they have done much damage. They are still in the bark, or between the bark and new wood, into which they will penetrate, if not disturbed, upon the approach of cold weather. Continue use of the "soap" remedies given last month.

The growth of the present season is now sufficiently mature for layering, or inarching, to increase or change the variety. Peg down and cover with earth the new shoots of propagating stools, and tie the branches of inarched stocks to stakes, or other supports to prevent shaking about by the wind.

If the month proves dry, water must be given to the seed beds, especially those of evergreens which should also be partially shaded from the hot sun. Trees transplanted in the spring may also require an occasional watering, but a good mulch is far better.

The plow, cultivator, or horse-hoe, should be run through the nursery rows frequently, to keep down weeds and lighten the soil. The hand hoe will also be needed to work closely about the trees.

Kitchen and Fruit Garden.

The labors of the judicious gardener are now being rewarded by supplies of various delicious edibles, which may be kept up until Jack Frost looks up the teeming earth for a season of repose and recuperation. The surplus of most kinds may be preserved for winter use. The space from which early peas, potatoes, etc., have been gathered, may be used again this season for quick-growing turnips, late cabbages, spinage, etc.

Asparagus—Keep clear from all weeds, and gather and clean the seed as it ripens, and sow at once if new beds are needed. Time is saved, however, by setting out roots in Autumn.

Beans will soon be ready for table use, and the young pods of bush varieties are excellent for pickling, and may also be kept good for the table by packing in salt. (See article on page 246.) Plant a few for a Winter supply.

Beets—In pulling for use, take them from the thickest parts of the bed, to allow the remainder plenty of space. Keep the ground well loosened and watered, and free from weeds. Mark by small stakes the earliest and best to be saved for seed.

Blackberries—Pick as fast as fully ripened, but be not too hasty, especially with the New-Rochelle, as some time is required to attain its full degree of excellence. Any surplus may be dried, preserved in bottles, as directed on page 214 (July No.), manufactured into wine, or the juice bottled, as directed in last number for currants.

Cabbages, Cauliflowers, and Broccoli—Hoe often, even twice a week is none too often. Set out plants for a late crop, and sow seed for Fall greens, and keeping in cold frames.

Celery—See article on pages 213, July, and 243, this No.

Corn—Keep out all weeds, but do not disturb the roots of the corn. Mark the earliest and most prolific stalks, to be preserved for seed. Examine to prevent depredations of the corn-worm which eats downward from the silk to the kernels.

Cucumbers are now attaining sufficient size for table use and for pickling. The yield will be increased by not allowing them to ripen, also by pinching off the largest runners. Reserve the best for seed, and remove all other buds from vines that are set apart for ripening seed. Ripe cucumbers, properly pickled, are excellent.

Currants and Gooseberries—Prune as soon as the fruit is gathered. Remove from one-third to one-half the old wood, and shape to tree form. (See recipe for bottling currant juice on page 215, July *Agriculturist*.)

Egg Plants—The growth and ripening of fruit will be hastened by placing a board painted white on the north side of the hills. Hoe well; hill slightly.

Espalier Trees—Keep well trained and pinch off superfluous growth.

Grapes should be zealously guarded against insect ene-

mies and mold. Tie the leaders to the trellis. Where the ends of the bearing branches have been pinched off, the side shoots will need to be shortened in.

Herbs—Complete the gathering and drying during the period of blossoming.

Hoe to loosen the surface and to destroy weeds.

Hops—Pick, spread until perfectly dry, and store in bags, or pack in bales.

Lettuce—Sow in vacant corners for Autumn use.

Melons—Remove all fruit, except three or four specimens to each vine; those remaining will be larger and of finer flavor. Place straw, or a board, under those nearly ripe, to protect from worms and rot; occasionally turn them to ripen equally on all sides, but do not injure the stem.

Onions—Gather for use or for market as soon as they ripen, but if to be kept for any length of time, leave them exposed to the sun, until properly cured. Sow for "pips," to be left in the ground during the Winter, for early use next season.

Peas—Most kinds have yielded up their fruit. Clear the ground from straw of early crops and feed it to swine. Fill the vacancy with turnips, or late cabbages, lettuce, onions, etc.

Potatoes—Remove and burn all diseased tops or haulm. Harvest and market early crops, and replant the ground as directed above.

Raspberries—Cut out all except two or three of the strongest young shoots for each root for the crop next year, and keep them properly trained to the stakes or trellis. Hoe in a compost of well-rotted manure and ashes.

Seeds—Save the earliest and best of all kinds. Label each one distinctly with the name, and time of raising; keep in a dry, dark place, secure from vermin.

Spinage—Sow at intervals for Autumn use.

Squshes—Remove eggs of the squash bug (*Coreus tristis*) from leaves, and destroy the insects already hatched out. Save the earliest and best squashes for seed.

Strawberries—Clip the runners of those in hills as they appear. Young vines may be transplanted the latter part of this month. It will pay to do the work carefully, and water as often as needed.

Tomatoes—Continue to trim the vines, and destroy worms by hand picking.

Turnips—See article on page 231.

Weeds—Save quarters by giving weeds no quarter. Cut down expenses by cutting down weeds before they have had time to ripen their seeds. Those whose seeds are nearly ripe, should be burned. Cast others into the compost heap.

Flower Garden and Lawn.

August heat is trying to the less hardy exotics. Great care and judgment are needed to carry them safely through. The great mistake of too frequent sprinklings and too few thorough waterings, is often made. Mulching is usually all that is necessary, but if, upon digging into the soil, it is found dry to the depth of three or four inches, take out earth near the roots, pour in a good supply of lukewarm water, and, when soaked away, return the dry earth. This will prevent surface-baking.

If you have any new plant or flower which you wish to perpetuate, now is a good time to note its peculiarities, and mark, by string or otherwise, so that the seed may be saved. As fast as those not wanted for seed complete their blooming season, cut them down if perennials, and pull them up if annuals, to give place to others. Late sown plants should be ready to transplant to spaces otherwise vacant during the remainder of the season.

Sweet Williams, carnations, daisies, phloxes, hollyhocks, polyanthus, campanulas, etc., will give bloom next season, if the seed is sown now.

Budding—This is a proper time to bud the rose, but the practice can only be recommended on a smale scale and for amateurs. The buds often die out in a few years. Oranges, lemons, magnolias, and many of the flowering shrubs may also be budded.

Bulbs—Such as the hyacinth and tulip, should be lifted as soon as the leaves turn yellow, the offsetts removed, and the bulbs dried and put away in paper bags until Autumn, then re-planted. This has a tendency to keep them more vigorous and truer to their colors. If necessary to remove them before the foliage is ripened off well, take up a ball of earth with the bulb, and re-set until the foliage is ripened.

Climbers—See that they have suitable supports.

Dahlias—Keep well tied up and prune where growing too thickly. One, or at most two good flower stalks per root is sufficient. A mulch about the roots in dry weather will benefit them. Cut away the dried flowers as fast as they lose their beauty. Watch for and destroy insects, especially the greyish worm which bores into the stalk and feeds upon its juices.

Fuchsias may now be propagated by cuttings and layers. Their continued bloom places them among the finest gems of the flower garden.

Hedges should receive their final Summer clipping during this month. Cut from the top. If cut late in the growing season, the new growth will not sufficiently mature before Winter.

Hoeing should be continued whenever needed.

Houses—If any are to be built this season, let the work begin at once. Make needed repairs and alterations in those already built. A cold house for grapes and other hardy plants can be built at a trifling cost—usually a loan to against some other structure.

Insects—Exterminate in every practicable way. Do not let them increase by a second crop at this season. Even if they have done all their injury for the season, allow none to weave their cocoons for next year.

Layers of many of the woody plants can still be made with a probability of their rooting before Autumn. Use wood of the present season's growth. Shoots laid down in early Spring, if well rooted, may now be severed from the main stock.

Lawn and Grass Edgings—Mow evenly as soon as 6 to 8 inches high. Frequent cutting causes it to thicken at the bottom. A sprinkling of guano water, or liquid manure, after mowing, will cause the grass to start with vigor. New lawns may be sown adding a little Winter wheat, or rye, to protect the roots during the Winter.

Mignonette will still bloom late in the season, if sown at once. It will also form good house-plants for Winter.

Pelargoniums—Start cuttings for a Winter stock to bloom in-doors. Thin out and head back plants to give them a good form.

Potted Plants will need care at this season. Water frequently, and loosen the surface soil, if not mulched, removing weeds and moss. Pot off a good stock of the various plants intended for early Winter flowering.

Pruning should have been mostly completed last month according to directions then given.

Roses—Keep up the war against the slugs. Budding may still be performed on late growing sorts, and layers of new wood pinned down. The remontants should now show a second bloom.

Verbenas—Layer plants for Winter flowering. The past few years have added many new seedlings, some of remarkable beauty, and others quite *fragrant*.

Weeds—Keep from the borders, walks, from growing among the grass upon the lawn, and from every foot of your premises.

Wild Flowers—Some may be found which, by careful cultivation, will prove valuable additions. The peculiarities of soil, shade, moisture, etc., where they grow naturally, should now be noted for future guidance.

Green and Hot-Houses.

Scarcely anything additional need be said with reference to these, as most of the ordinary house plants are now in the open ground. A good supply of potting earth should be prepared, both for present and future use. It is better after having lain in the heap some months, hence a large stock should be provided. A good potting soil is made of 3 parts leaf mold, 1 part loam, 1 part sand, and 1 part old manure.

Houses should be put in readiness to receive tender plants the latter part of next month. It is always better to have all painting done some weeks before plants are brought in.

A good stock of cuttings of various kinds, intended to form late Fall and early Winter flowering plants, should now be put in and properly cared for. A house, or frame is needed to start them well.

Potting should be attended to now, that the plants may be ready for an early Winter bloom.

Apiary in August.

Prepared by M. Quinby—by request.

In sections where the crop of buckwheat is raised, bees will begin to store honey from it in the surplus boxes, from the 1st to the 10th of this month. All boxes containing the white honey, must now be removed, if it is wished to keep it pure. A box may be nearly full of clover honey, and a few ounces of buckwheat outside, or next the glass will make it appear as if it was all that quality. Four pounds of one quality, is worth as much in market, as six of the other, hence the advantage of keeping it separate. Where there is no buckwheat, there will be nothing further added to their stores—except, perhaps, on the western prairies; and all surplus boxes may be removed now. All cells not sealed up, will be likely to be emptied soon. Full boxes certainly should be taken off, as the honey grows darker when left on. Do not put on glass boxes now unless there is a fair prospect of their being needed. A weak colony would be likely to do nothing more than soil the glass with propolis, and make it look bad for another year.

Continue the use of the sweetened water, and other means to destroy moths and worms. Keep all dust and filth swept out clean from under small colonies. Weak swarms in the movable comb hive may be much benefited by giving them a comb or two filled with sealed brood from a strong colony. The brood hatches in a few days, adding greatly to their numbers. New colonies that were formed by simply dividing the combs, as mentioned in Apiary in June, should now be examined, and if the division without a queen was strong enough to construct combs, while rearing one, they would make all store or drone comb, which is unprofitable for rearing brood. Remove such combs now, replacing with empty frames, that worker combs may be constructed instead. The honey so stored is best quality, almost equal to that in the surplus boxes and may be used for the table, or it may be put away to assist some light colony through the winter.

Exhibition Tables at the Office of the American Agriculturist.—

The following articles have been presented since last report:

Fruits, etc.—*Strawberries*—White Strawberries, (very fine), from Robert Benner, New-York.... Triomphe de Gand, (very fine), from A. Child, Newmarket.... Triomphe de Gand and British Queen, from F. A. Wilkisson, 926 West Washington Market, N. Y., and grown by Mr. Knox, Pittsburg.... Great Admirals, from W. S. Carpenter, 329 Greenwich-st., N.Y.... Russell's Prolific—a new seedling—from Geo. Clapp, Auburn, N. Y.... White Alpine Strawberry—seedling—from W. S. Carpenter, Rye, N.Y. .... Cutter's Seedling and Triomphe de Gand, (both been in bearing six weeks), from R. & G. Marshall, Poughkeepsie, N. Y.... *Cherries*—Triumph of Cumberland and Reine Hortense, (fine), from David Miller, jr., Carlisle, Penn.... *Currants*—La Versalles Red, and Red Cherry, from E. S. Woolsey, Milton, N. Y.... White, (very full bunch), from C. Smith, Morrisania, N. Y.... Red Dutch, (2 years old cuttings), and Black Naples, (both fine), from Mrs. E. C. Wheeler, Fairmount, N. J.... Red Cherry, Red Dutch, White Transparent, White Provence, (very fine), White Dutch, White Clinton and White Grape, from W. S. Carpenter, Rye, N. Y.... Red Dutch, (very fine), and Black, from W. P. Heins, Woodstock, N. Y.... *Raspberries*—Doolittle, Black Cap, Brinckle's Orange, and Anges Fillbasket, from W. S. Carpenter, Rye, N. Y.... Impetuale, (fine), and Hornette, (both new), from R. & G. Marshall, Poughkeepsic, N. Y.... *Gooseberries*—From Mrs. Hall, Williamsburg, L. I. From Mr. England, Bushwick, L. I.... From E. & G. Marshall, Poughkeepsie, N. Y.... *Mulberries*—Everbearing and 2 other varieties, from Mr. Tuttle, New-Haven, Conn.... *Apples*—Roxbury Russet, from Henry Day, English Neighborhood, N. J.

Flowers, etc.—Cut flowers, from A. S. Fuller, Brooklyn, L. I.... Fuchsias and Nasturtiums in pots, and cut Flowers, from Mrs. O. Judd, Flushing, L. I.... Cut Roses—Reine Hortense—from W. A. Burgess, Glen Cove, L. I. .... Cut Blooms of Magnolia macrophylla and Thompsoniana, (very fine), from Parsons & Co., Flushing, L. I. .... Gloxiana in pots, (very fine), from A. Bridgman, 876 Broadway, N. Y.. Cut Flowers from Jacob Braun, Williamsburg, L. I.... Cut Flowers and Bouquet, from Prince & Co., Flushing, L. I.... Cut Roses, Heliotrope, Honeysuckles, etc., from Wm. A. Burgess, Glen Cove, L. I. . Arum dracunculus and Dragon Flowers, from H. T. Haviland, Brooklyn, N. Y.... Marchantia polymorpha, from P. V. Leroy, N. Y.... Cut Roses from A. Cummings, Esq., N. Y.... Cut Flowers of Cimicifuga racemosa and Pyrola elliptica, from Mrs. E. C. Wheeler, Fairmount, N. J.

Vegetables, Seeds, etc.—New Potatoes grown without tops, from T. W. Field, Brooklyn, L. I.... 29 Potatoes, crop of a three-eyed piece of Early Sovereign Potato, planted April 8, 1863, from Wm. F. Heins, Woodstock, N. Y.... Wild Mexican Potato, planted April 10, 1863, and taken up June 27, 1863, and Kidney Beans, from G. M. Usher, Port Richmond, Staten Island, N. Y.... Heads of Timothy 11 inches long, grown on reclaimed swamp, from T. Hale, Wales, N. Y.

Implements, etc.—Model of Dikeman's Patent Corn Marker, from Dikeman & Hewlett, Hempstead, L. I.

Miscellaneous.—Trophies from Secessia, viz: 25c. Shinplaster, Bone Ring, Musket, Trumpet, and Gloves—from 1st Regt. N. C. Cavalry, per Mr. Sharp, New-York. ....Very small Hen's Egg, from Mr. Nostrand, Flushing, L. I.... Large Dorking Egg from Rev. J. Weaver, Fordham, N. Y.... Very small Bantam Eggs, from Robert Thompson, Weeksville, L. I.... Wine—Sorghum, (fine), from Rev. A. Myers, Springfield, O.... Currant Wine, J. C. F. Rommel, N. J.... Clothes Washer, W. M. Doty,

Containing a great variety of items, including many good Hints and Suggestions which we give in small type and condensed form for want of space elsewhere.

State and County Fairs—Our List.—On page 250 will be found a list of *all* the State and County fairs of which we have any knowledge. We have been very diligent in watching the papers for reports of meetings, appointments of fairs, etc., and both in this way and through our correspondents we have only learned of those there given. May we not appeal to our readers, especially to such as are interested in Agricultural Societies, to furnish us the information at once, by marked papers, premium lists, or letters, telling the time and place of holding any County or State Fair which is not recorded in the list?

Royal Agricultural Show a Pecuniary Failure—Rain and Crops in England.—Mr. Judd writes in a postscript to our letter dated London, July 5th, that "the experiment of holding the Great Annual Exhibition of the Royal Agricultural Society, in London, at a time when there were so many other attractions, proved a failure pecuniarily, though very fine as a show. The total receipts amounted to £12,000 ($60,000), but this was from $15,000 to $20,000 below the expenses. The *weather* here is still very rainy—it pours down every other day, and drizzles during parts of the intervening days. It would hardly seem possible that the hay crop should be gathered in even tolerable condition, or that the wheat crop should make any progress. Considerable fears are expressed here as to the prospects. We can not rejoice at the losses of our friends elsewhere, even though it may benefit us; but perhaps Providence may compel jealous foreigners to aid us in bearing part of our expenses, by compelling them to purchase our grain crops...."

The Homestead Law.—The following letter from Speaker Grow, interpreting this law for a Kansas subscriber, will explain itself:

SPEAKER'S ROOM, June 20, '62.

Dear Sir.—No one person can take, under the Homestead Act, over a quarter section, and that he can take without any reference to how much land he owns, if he occupies and cultivates as required by law. But if he lives on less than a quarter section, he can take adjoining, provided that (which) he takes with what he has shall not exceed a quarter section. Your owning land in Kansas does not prevent your *settling on and cultivating* either an adjoining quarter section, or any other elsewhere.

Yours truly, G. A. GROW.

Settlements under the Homestead Act.—"J. C.," "H. W.," Melrose, will see by referring to our last issue that we advise the formation of companies, say fifty families or more, in making new settlements. This plants all the institutions of civilization in the wilderness at once. Get up such a company or join one already formed, if you move at all.

The Agriculturist and the Ladies.—"G. E.," Pa., says, a wife in his neighborhood threatened to leave her husband, because he talked of dropping the *Agriculturist*. He does not say how far from him the wife lived, but we have a right to guess. "Served him right." What sensible woman could be expected to keep house without our hints on household matters, floriculture, and our recipes?

Strawberry Exhibition—Explanatory Remarks of the Committee.—Our last number was a little delayed, and we were enabled to insert the *Awards* made by the Committee of Judges on the Strawberry Exhibition, reported upon more fully on pages 240 and 241, but we had no space for other remarks, which we here give. The hints will be of value to Societies offering prizes for similar exhibitions:

"The Committee appointed to examine the Strawberries exhibited at the office of the *American Agriculturist*, offer a few explanatory remarks. They have selected the Triomphe de Gand, as the best for general cultivation, and by this they mean the best for market. The best berry for market is the one which, for the time being, will net the greatest profit per acre, under good cultivation. This distinction the Committee believe, belongs at present to the Triomphe de Gand. But there is another prize offered for the best market berry. Now in the Committee's view, this prize also belongs to the Triomphe de Gand; but, being requested to do so, they have selected another popular kind, the Wilson's Seedling, but would state that they deem it in quality quite inferior to the Triomphe de Gand; it is, however, large, firm, very productive, and sells for a good price.

"The Committee would suggest, that on future occasions the list be headed with a prize for the best berry, quality alone to determine. A prize might also be offered for the best berry for the garden, and another for the best for the field, retaining the excellent feature of the present list, of a prize for the best dish of the leading kinds, which should come in, however, before the prizes for collections, so that the judges may select the best, whether in a collection or not, and avoid the anomaly of giving a first prize to a second class dish, as has happened on the present occasion. The Committee can not close without congratulating the Proprietor upon the good management and entire success of the exhibition, and expressing a hope that these exhibitions may be often repeated."

Poisoned Sheep.—"M. W.," East Taunton, Mass., says he has used butter forced down the throat with entire success for thirty years. The sheep are probably poisoned with laurel, though he does not say so. The oils are effectual remedies for some kinds of poison. Iris safer to extirpate the laurel.

The Rose Slug.—Whale oil soap, four lbs. to the barrel of water, applied with a syringe, is the best remedy we know of.

Butcher's Offal for Meas.—Nothing better to start laying. But it is almost certain to give eggs a fishy flavor, which, however, only persons of delicate taste will notice.

Butter from Scalded Cream.—"J. C. R.," Pittsfield, Ohio, has tried the method recommended in a former article with entire success. The method is, to put the cream into a dish set in a kettle of hot water.

Sour Milk and Preparation of Meal for Calves.—In answer to "S. T. L.," Dwight, Ill., we quote from Allen's book on "Domestic Animals:" "The milk should not stand more than half a day before feeding to young calves. As they advance in age, it may be fed rather older, but should never be allowed to become sour; nor should it ever be fed cold." Sour milk is neither natural nor wholesome for calves. To prepare meal for them, scald it, and add a small proportion of flax seed. Wheat bran or oat meal, with a little salt, added together with fine hay, is good food for calves after weaning, if pasturage is short.

Choked Cattle.—"J. E. W.," of N. J., says "seize hold of the tongue of the animal and give it two or three jerks, harder or lighter according to the age of the animal." Sometimes simply rubbing and squeezing, with a firm pressure, the outside, will remove the obstacle.

Some Dogs.—A farmer's daughter puts in a demurrer against our sweeping condemnation of dogs—because her dogs churn. For five years they have done the churning in a large dairy, saving a great deal of hard labor to the women of the household. Now that is sensible, and we glory in the dogs that work—and still more in the women that know how to get service out of them. We have never supposed that the Almighty made a mistake in creating dogs. They have their uses like other animals. A horse is excellent in the stable, but a poor parlor companion. A goat is very good cropping scrub oaks, blackberries, and brier roses, but we should not like him in the orchard, under the table, on the sofa, or in bed with the children. It is your sleek, useless parlor dogs, that we object to. A dog at a churn or grindstone, or what is better, under a garbage cart helping his master, we glory in. No more useless curs. "Your work, Mr. Cur, or your neck," should be the motto.

Dry Hay for Cows in Summer.—Cows sometimes get a surfeit of grass, especially in wet, warm weather, when the grass is succulent and rank. This feed distends the bowels uncomfortably. An armful of dry hay once a day, will serve to absorb some of this moisture, and benefit the cow in several respects.

Poultry in Indiana.—"C. G. E." Poultry can be sent to the N. Y. market in the winter season from points near railroads at a profit, if nicely fattened.

"The Market Book."—Mr. Thomas F. DeVoe, Butcher, in Jefferson Market, and member of the N. Y. Historical Society, appears as the author of a historical work of very great value. The first volume is a history of the public markets of New-York, with sketches of many of the principal butchers, from the earliest time down to some now living. Statements and descriptions are introduced, interspersed with anecdotes, so that one gains a very clear idea of the habits of the people, the laws of the city and the location of the markets; and in whatever has any connection with the sale of human food, the book is particularly full and clear. The history of public buildings, streets, squares, ferries, of the origin of now prominent and wealthy families, of the Revolutionary war, and of important civil and military events as successively they had a bearing on the craft, give to the work ever-varying interest. We have perused it with very great pleasure and instruction, and find everywhere evidence of great discrimination and accuracy. It has especial interest to the agriculturist, because not only the first introduction of neat cattle and small cattle into New Netherlands, is recorded, but changes in the character of market stock are noted, as well as record made of the most notable animals; and in a subsequent volume, in which histories of the markets of other cities also will be given, Mr. DeVoe purposes to discuss the ways in which various kinds of meat, and other produce, are brought to market, and to describe every article of food sold in the public market, the manner of its production and how it is prepared for sale. We are impatient for the second volume. The price of Vol. I. (large 8vo., 621 pages, and beautifully printed) is $2.50.

The Wheat Aphis.—Last year, at the East particularly, the Aphides, or plant lice, were very numerous on various kinds of grain, on cherry trees, etc. This year, while this continues in a less degree at the East, the West has been alarmed over large sections by the prevalence of the aphis in the wheat heads to an extraordinary extent. We have received 15 or 20 letters containing specimens of wheat heads thus affected. Some of the letters contained also other little, rough, dark colored insects with light bands, which we recognize as those devourers of plant lice, commonly called tigers. There is little to fear from the aphides, except when in immense numbers, at which times they greatly reduce the strength of the plant, and the grain does not fill. The damage done is not ordinarily perceived before thrashing, when the grain will be found lighter. We know of no cure, or defense against them. As they increase, the destroyers—ladybugs, tigers, and certain flies also—multiply, and will keep them in check.

Insects on Gooseberries.—"J. H. D.," Kansas. The insects described are probably red spiders.

The Bureau of Agriculture.—Isaac Newton, of Pennsylvania, Commissioner, and Richard C. McCormick, of New-York, Chief Clerk. This is the state of the case. It is our duty to our readers to announce the fact. We wish to say nothing more on the subject at present.

Parson Brownlow's Book is a narrative of personal experiences in East Tennessee, during the eventful year just past, with much collateral history and exceedingly interesting. 458 pages, 12 mo. Published by G. W. Child s, Philadelphia. Price $1.25.

A Pamphlet on Bee-Keeping, by Martin Metcalf, contains many valuable hints, some new ideas, and elucidates his method, and patent hive. 96 pages, 12 mo., for sale by Saxton, New-York.

Disease of Watermelon Vines.—"F. C. A.," Windham, O. We have no acquaintance with the white worm which seems to be the cause of the disease. The tow around the vine would be more likely to be effective if it were watered with liquid manure every day. Bugs seldom get the start of thrifty plants. Possibly a change of spot for planting the melons would remedy the difficulty.

Pine Leaves a Mulch for Strawberries.—"J. W. H.," N. H. We have no experience with this kind of mulch, but see no objection. Two inches in thickness, or even less, will be enough.

Russell's Seedling Strawberry.—Mr. George Clapp, of Auburn, N. Y., made a beautiful exhibition of this new, large, and finely flavored seedling, at the office of the *American Agriculturist*, on June 28. The berries were seen by most of our prominent pomologists, and many others, and universally admired. The berry is very large, scarlet, of fine flavor, excellent quality, apt to be hollow cored, said to be very prolific, pistillate. See advertisement.

Triomphe de Gand Strawberry.—"W. S.," Bordentown, N. J., thinks this the best of thirty varieties he has tried. His neighbors are digging up other varieties and planting with this.*

Lychee Nuts.—A new nut, or fruit, from China has recently appeared in our market, called Lychee. It is the fruit of the *Nephelium litchi*, and consists of a pulpy fruit surrounding a large hard seed, the whole en-

closed in a soft shell, consisting of numerous angular plates like the scales of an alligator, on a small scale. The pulp though dried considerably is very delicious.

Variety in Fruit-Growing is a matter of vital importance. Strawberries, perhaps, pay as well as any thing else, but the season only lasts three or four weeks. The same labor could be employed in picking raspberries, currants and blackberries, which come along in succession for two months after, when the Fall fruits are ready. Any one fruit is liable to fail, and a variety divides the risk. A fruit-grower who has a variety will ordinarily succeed better than one who makes a specialty of the strawberry. Of the latter fruit the Wilson's Albany, and Triomphe de Gand, are among the best well-tested varieties.

Strawberry Culture.—"E. B.," Poughkeepsie. The more thorough the preparation the better. Turn in the clover immediately. Use the subsoil plow, if the land is at all heavy. Manure after subsoiling, harrowing or plowing it in three or four inches deep. If the runners have been struck in thumb pots you may look for quite a large crop next year.

Profits of Fruit Growing.—"G. W. C.," Wings Station, asks what kind of fruit is most profitable, and what net profit fruits have been known to yield? It is difficult to give a precise answer to these questions. A gentleman in Delaware expects to get this season a crop of 50,000 bushels of peaches from about 120 acres. If he gets two dollars a basket his crop is worth 120,000 dollars, or a thousand dollars to the acre. As much as this is sometimes realized from fruit. But the next 3 years the same trees may yield nothing. In cultivating the small-fruits, from two to four hundred dollars an acre are not uncommon results.

Renewal of Strawberries.—"W. H. W.," Canada East. Strawberry beds will last a great many years, but most fruit-growers find it safest to renew after two full crops. The increased productiveness of the beds pays, and the ground is easier kept clean.

Cranberries from Seed.—"A. T.," Iowa. The objection to producing plants in this way is the long time it takes to get them into bearing. They will grow from seed in any moist loamy soil, but a plantation can be had much sooner from vines transplanted with care.

Cranberries on High Ground.—"E. P. T.," Mc. We have seen them growing in such localities, but consider it doubtful whether any will do as well there as on wet land.

The White Doyenne Pear is the old Virgalieu, which has generally failed at the East, except on the quince stock. The farther a pear or other fruit tree is removed from its wild state, the fewer thorns or other appendages of a native condition are seen. Hence a grafted tree has no thorns or spurs, while an ungrafted tree often shows them.

Catawba and Lenoir Grapes.—"F. B.," Wis. We have never heard of the Catawba turning black. The Lenoir is of nearly the same color with the Herbemont, dark-blue or violet, and for some time was thought to be identical with it.

Delaware Grape in Maine.—"E. P. T.," of Lewiston, Me., says this grape matured perfectly in open-air culture at that place.

Sweet-Sour Apples.—"J. E. Y.," Ohio, asks if there are apples sweet upon one side, and sour upon the other. We have eaten such apples. They are a sport of Nature, and not the result of any direct effort on the part of the cultivator to produce them. We have eaten splendid Northern Spy's grown upon the sunny side of the tree, and insipid specimens grown in the shade. The red cheek of an apple we think is of higher flavor than the other, which the sun has not kissed. In the sweet-sour apples, the sun has carried the joke a little further, and turned all the acids upon one side into sweets. Such trees are valuable only as curiosities.

Apples Preserved by Salt.—"G. L. W.," Kings Co., recommends packing apples in barrels that have contained salt, to preserve them. We want at least several experiments before we can indorse it.

Hardy Apples for Minnesota.—"J. O. E.," Goodhue Center, Minn. Apples from Canada and Northern New-England, will probably suit your climate. Fameuse, Baldwin, Roxbury Russet, R. I. Greening, are very hardy. It is quite possible that seedlings raised there may prove more hardy than any thing from abroad. The experiment should be tried. The location for an orchard or nursery should be well sheltered from prevailing winds by a belt of evergreens, if possible. Shelter alone will make a difference in climate of three or four degrees of latitude. The cutting back in August is a good plan, but a well drained soil is better, to ripen the wood.

Northern Spy.—"T. W.," of Canastota, says he has fifty trees of this apple set twelve years. In 1849 he had three or four bushels, in 1860 sixty bushels. He has kept the ground cultivated all the while with corn and potatoes, until last year when he seeded down. He says the trees need a good deal of thinning and high culture.

Plum Stock for the Peach.—"J. B.," of Richview, Ill. In England the plum stock is universally used for the peach. It is thought to make the tree more hardy, and to give it a dwarfish habit. If the wild plum is a free grower, peach orchards would probably do well upon it. We have never seen the experiment tried, but should have no doubt of its success in skillful hands.

Tar on Fruit Trees.—F. A. Jones, Ohio. If the tar was applied directly, it will be likely to kill them. Young fruit-growers frequently "get bit" in this way. The tar should be applied to a strip of stout canvas before it is put around the tree. The only remedy is to scrape off the tar if the trees are not already dead.

Budding the Peach.—"S.," Bradford Co., Pa. Any of our articles on budding in back numbers will convey the desired information. Single buds or eyes are the leaf buds. Any one who has ever noticed a shoot of new wood can detect the difference between a blossom and a leaf bud in a moment. The process of budding is so simple, that a child can perform it, after a little practice. See full explanation in July number.

Augers Quince.—"A. B.," Ill. This quince is cultivated principally for dwarfing pears. The fruit is not desirable.

Shortening-in Evergreens.—"G. W. C.," Wings Station. This will thicken the foliage to any desired extent. The Arbor Vitæ, Norway and White Spruces, bear the shears well. They can be trained to a perfect cone, or sheared into a hedge of almost any form.

Pruning Evergreens.—"H. D. C.," Florence, Mass. The best time is while they are making wood or just before. Hedges are usually clipped in May. The spruces we have shortened-in, in June. They should be pruned in the shape of a true cone, the longest limbs at the bottom. Each tier of branches should be shorter than the one below. If you shorten above it forces growth below. An evergreen stripped of its lower limbs is a deformity. Better cut it down and start a new one.

Soil for Nursery.—"Z. J.," Wis. Any good loam suitable for corn will make good land to grow young trees on. We have seen fine evergreens growing on reclaimed swamp. The soil should be well drained. Dry apple seed should be soaked in water before planting.

Hedge Plants for Gardens.—"H. A. B. C.," Kansas. A good hedge will of course take up some land, but it will make what remains very much more valuable for all garden crops. An evergreen hedge breaks off winter winds and enables us to cultivate fruits and flowering shrubs that would perish without their protection. The Osage Orange will probably do well in Kansas. We should prefer two-year-old plants, but would use four-year-old, if younger were not to be had.

Norway Spruce for Shelter.—H. Grundy, Ill. It will be much cheaper to purchase the plants than to try to raise them from seed. It requires considerable skill to get the plants through the first season, and special conveniences which only nurserymen have. The growth is slow at first, but rapid after the fourth or fifth year. Plants from one to two feet high are the most desirable for setting—those thick and bushy at the bottom. Small trees can be had for four or five dollars a thousand, but if time is any object with the cultivator it is better to buy a little larger and pay more. Not a root should be suffered to get dry in transplanting.

Early Sowing of Oats.—"J. L.," Pa., claims as results of this practice, stiffer straw, a larger yield, and heavier grain. He is quite right.

Hop Culture.—"L. M. M.," Port Covington. In the Summer of 1857, we visited the hop-growing districts in Otsego County, and gave a full description of the methods of culture and curing adopted there, for which see *Agriculturist*, August and September 1857. The practice of suspending wires from large border poles, and substituting strings for hop poles was then coming into use. The expense of furnishing a yard with poles was estimated at about two hundred dollars per acre. It was claimed for the wires that they were cheaper, and the cords saved much labor in handling poles. The hop-growing interest is very limited in comparison with other agricultural products, but shall receive its due share of attention.

Wheat in Utah.—"T. B.," of Great Salt Lake City, says ninety bushels of White Taos wheat were grown on a city lot, one and one quarter acres, a rich black loam, irrigated three times. Another man in Cache Valley raised 71½ bushels on one and one quarter acres. Seventy two bushels of wheat to the acre makes a "great country."

Sorghum in Minnesota.—A subscriber writes that eighteen gallons of syrup were made from cane grown on nine square rods in Morrison County.

Chess Again.—"J. A.," Ashtabula Co., O., says, he is in for the premium, and now knows just how to get it. He tried last season, but somehow, what he took for *chess* stalks, bore *wheat* heads, and concludes he did not sow in the right phase of the moon. He is now carefully watching the moon, and is so positive of it next year, that he wants the "shiners" kept for him, unless we will send him a few in advance.—Can't do it, friend Josiah, but will keep our bank account ready, to draw out that amount at any time.—Ed.

How many Pounds of Corn to the Bushel?—"J. S.," Tyre, N. Y. Previous to 1857 the standard weight of corn was fifty six pounds to the bushel. Two pounds were added by the legislature of that year which operates unfairly upon eastern farmers as their corn weighs more per bushel than the corn of the west which constitutes the great bulk of what is in the market. But the speculators not satisfied with this, demand, in some places, sixty pounds to the bushel, which is a still further shave upon the farmer's profits. Farmers should have conventions to protect their own interests and refuse to sell except at the standard weight.

Pedigree Wheat.—"J. F. H.," Lancaster, Pa., thinks this wheat very fine, a single head measuring 7 inches. It is very productive and later than the common wheat. Any notes throwing new light on the cultivation of farm crops will be acceptable.

Ground Bone Heating.—"T. L. H.," Wilkesbarre. Heating to the utmost, we should think, would release ammonia. Any strong acid would decompose the bone, and lime would increase the heat. We think if the ground bone were well dried before it was packed in barrels it would not heat. If the bone had any thing mixed with it, it would be difficult to fix the price.

Sumach Tannery Refuse.—"D. W. R.," Greenville, Ct. It will probably answer for mulching as well as other vegetable matter, and can not be worth much for manure, until it is composted. We should be glad to hear of experiments with it.

Liquid Manure vs. Muck.—"T. G. S.," West Brattleboro, Vt. It takes off the profits to cart muck two miles. The objection to carting the urine to the field is that it will not be done often enough to save its most valuable constituents. The moment the muck absorbs it, it is safe. If it lies fermenting in the vault a week or two, especially in warm weather, much of the ammonia escapes. If a cistern be attempted we should make a large one, mix water with the urine and apply it with a watering cart to grass and other growing crops.

Good Squash Seed.—L. L. Knox, Wis. The seed should be taken from a well ripened squash, should be well dried, and kept in a dry place.

Asparagus Bed.—Z. Cooke, Wis. If we could have the handling of the roots we should prefer the three-year-old roots to the seed. It takes three years to get a good bed from seed. If the old roots are not badly mutilated they would yield some cuttings the first season, and plentifully the second. Two-year-old roots are best.

Cauliflowers—Making them Head.—"A constant Reader" transplants them into the cellar in good soil in the beginning of winter. With an occasional watering they head finely.

Lilliputian Top-Onion.—"J. W. B.," Macedon, O., claims for this onion, that it is milder than any other, more uniform in size, more sure than the common seed. One pound contains about 8000 miniature

onions, and may be sown by hand or drill. These are important items, if further cultivation proves them true.

French Tree Tomato is a novelty yet, not thoroughly tested; but from last year's experience, we do not want it. It is not *tree* enough to stand alone.

Cotton in Kansas.—"G. L.," Snobny Hill, Kansas. The sample of cotton sent us is a very fair article, of "medium" grade, worth to-day 44 cents per lb. There can be no doubt that this staple can be grown several degrees further north, with profit at the present prices. Kansas is a good field for the experiment.

Preparing Chickory for Use.—"S. N. Y." Dig the roots with a potato fork, in the Fall, before hard freezing; wash and scrape them, and split the larger roots lengthwise, and cut into pieces 3 inches long. Dry in a slow oven or heated room until there is no moisture, avoiding scorching. Pack in bags and hang in a dry room until wanted for use, when the roots are cut into smaller pieces and roasted and ground like other coffee. Mix 1 part of the chickory with 3 parts pure coffee. We do not advise its general use, however.

Great Crops of Potatoes.—S. J. Wells communicates to the Country Gentleman the result of experiments with one half bushel each of five varieties of Mr. Goodrich's seedling potatoes raised in Onondaga Co., N. Y. They were planted on a rich loam of clay and gravel, with no manure, though the land was heavily dressed for tobacco two years previous. The tubers were cut into pieces of 2 and 3 eyes each, and dropped in drills 1½ feet apart in the row, the 22d of April. Some varieties occupied more ground than others, owing to a larger number of eyes. When dug they were perfectly sound, with the exception of a few of the "Copper Mine." The following results were obtained:

Copper Mine....	22 bush. at rate of	594 bush. per acre.
Cuzco.....	20 do	560 do	do
Pink Rusty Coat.	17½ do	475 do	do
New Kidney.....	15 do	400 do	do
Garnet Chili.....	14 do	378 do	do

Mangel Wurtzel Seed to the Acre.—"D. G. E.," Ill. The rule is four pounds of beet seed to the acre. We generally use a little more, preferring to have a surplus of plants.

Carrots as a Field Crop.—"R. H. S.," Pa. The seed is drilled in rows thirteen inches apart, if you use hand cultivation; thirty inches, if you use horse. The roots are stored without washing. Clean cultivation and manure are the secrets of success.

Potato Nomenclature.—"W. B.," Kansas. This comes appropriately under the work of Horticultural Societies. The names of most varieties are pretty well fixed in the East, and we are making progress in this matter every year.

Digging Machines.—The purchaser of the O'Reilley Terraculor invention, a large sized specimen of which machine was exhibited some time since at Rochester, Mr. H. C. Hepburn, of this City, has constructed one on that principle, but on a smaller scale than the one then exhibited, calculated for a single pair of horses. The teeth penetrate the earth to the depth of eight inches, and cut about twenty to twenty-two inches in width, leaving at least the surface in a light and finely pulverized condition; but it is yet evidently too hard of draft for two horses. Some changes will have to be made, we judge, to render the draft of the machine comfortable work for one span.

Recently another implement of this character, Comstock & Glidden's Rotary Digger, from Milwaukee, has been exhibited in operation in this vicinity. We saw it dig up heavy stubble ground to the depth of about eight inches and nearly three feet in width; its draft, also proved much too severe for one span of horses. The structure of this machine differs considerably from the other, and its effect on the soil differs also, in that it lifts the subsoil more, but does not leave the surface so finely pulverized. From what we have seen we are entirely satisfied that this method of tilling the soil may be made feasible and economical. Neither of these machines is perfect by any means, but a great advance has been made. We regard them with great favor and shall watch with interest their further development, but as yet would not like to express a decided preference between them.

The effect of Tillage on the Moisture of Soils.—"A. S. D.," Ohio, asks if new land will not make better pasture than that which has been plowed, and if it will not stand drouth better? There is a manifest reason why both these questions should be answered in the negative, even if we had no facts to sustain it. New land or virgin soil so far as it is richer, will, of course, bear more grass than soil often plowed and cropped. But if the soil were equally good, we have no doubt that the plowed land would bear the most grass. Plowing loosens and deepens the soil, and of course gives a deeper pasture ground to the roots of grasses. This loosening of the soil gives freer access to the air, which imparts moisture and guards against drouth.

Horse-Hoes.—"S. H. B.," Newtown, Conn. Shares' Patent is one of the best. They are generally lighter than the cultivators, and work admirably in smooth land. The agricultural stores at Hartford, New-Haven, or at Bridgeport, will probably furnish them.

Angle Worms.—Mr. L. R. Murray, of Jefferson Co., N. Y., wants to know if a *very large number* of angle worms in a soil, originally clay, but worked and manured so long as to be tolerably mellow, effect any injury; and if so, what is the remedy? We have never seen any evidence of serious injury effected by them. It is even thought that their presence is advantageous to the soil, by rendering it more porous, and otherwise making it finer and better.

To Prevent Wall Paper from Fading.—A Connecticut subscriber recommends a lump of alum as big as hen's egg dissolved in 6 quarts of paste.

A Short Method with Night Caps.—"H. H. B.," Wis. Aunt Cinda's method is to tie a knot in each of the opposite corners of a handkerchief, about two inches from the end. Put it on the head one knot before, and the other behind, and tie the other two ends under the chin. Look in the glass and keep from laughing if you can. A shorter method still is to put a not before the whole kerchief instead of *knots* in the two ends. We eschew night caps and dogs. A clean head makes a clean pillow case. Soap and water at the roots of the hair are better than cotton at the other end. Keep the head cool.

Why Grease Bread Pans?—"Eunice," of Columbia Co., Wis., does not see the utility of the almost universal practice of greasing bread pans before baking. She does not do it. In the multitude of counsellors there is wisdom. Who speaks? Many people bake the bread on the oven-bottom, sprinkled with ashes, and some to the ashes, or instead of them, add flour and caraway seeds. Such use no grease.

Rancid Butter is said to be cured by mixing soda with the cake or cookery in which the butter is mixed. We doubt the cure and still more the wholesomeness of the compound. Fresh butter, if you please.

Medicine for Summer Complaint. J. L. Holmes, Bristol Co., Mass., says, steep rhubarb root in water, add molasses, and boil to a syrup. If the patient is weak, add a teaspoonful of brandy to a teaspoonful of syrup, and give a teaspoonful 2 or 3 times a day.

Drying Sweet Corn for Succotash.—"J. F. H.," Lancaster, Pa. We know of no good oven or furnace expressly for this purpose, and one is hardly needed for preparing family supplies. Where a business is made of drying apples and other fruits they have an apparatus expressly for the purpose. For the family a bushel or two may be dried with the common stove without any difficulty. The corn is boiled slightly in its milky state, scraped or cut from the cob, dried a day or two upon sheets in a bright sun, carrying them in at night, and then finished off in a brick or common stove oven. No family should be without a full supply of this article. Succotash once a week is wholesome, economical, and "not bad to take."

Rain in England.—From tables kept in London, England, we find the amount of rain which fell in 1861 was 20.7 inches; the average fall there is 25.4 inches.

Climate of Washington Territory.—J. H. N., a citizen of that region says: "The climate is much milder than in the States. The farmer can work half of the time in the winter season. I have left potatoes in the ground and found them uninjured in the Spring. Cattle need very little foddering in winter. Corn yields about forty bushels to the acre, wheat the same, and potatoes five hundred bushels; other grains in proportion."

"Electric Weather Glass, or Storm Indicator."—J. S. Fish, Grafton Co., N. H.—Just to test this instrument, advertised by Lee & Co., we obtained one. It is a glass vial attached to a strip of metal, containing camphor dissolved in alcohol and water to saturation, which is sometimes clear and limpid, and sometimes cloudy or in a crystalized state. It is an old philosophical toy, but after long watching we can trace no direct or uniform connection between the condition of the fluid and the subsequent state of the weather.

Plants by Mail.—"H. L. S.," Provo, Utah. Any thing under eight ounces may be sent by mail. This will include all the small fruits, and some of the large ones. The better way probably will be to send to St. Louis, for such plants as can be had there of the nurserymen, and for the rarer plants to some Eastern nurserymen or florists, who have or can procure almost any plant desirable, and can forward it in the best way. The selling of seeds and plants is not our business.

The Word "Balance," in the sense of remainder, is derived from counting-house usages, and is not so strictly incorrect as inelegant.

"The Freedom of the City."—"M. E. M." asks: "What is meant by granting the freedom or liberty of a City to an individual, as an expression of great regard or esteem, by its citizens?"... It means very little in this country, nothing in fact but a compliment. In the olden time it conferred certain valuable privileges and immunities; and making a man a citizen, endowed him with certain profitable rights. It was often granted in order to induce men of reputation in science, letters, or arms, to make the city their residence; and in Europe it is even now so used. Thus, as one of the inducements held out to Baron Liebig, to take up his residence in Munich, "the freedom of the City" was voted him, and we suppose he became for life one of the City corporation.

Snow in Utah.—"T. B.," informs us that the snow in the mountains there was 34 feet deep in April, and men had to go on snow shoes to free telegraph wires.

Silk weed a Substitute for Cotton.—"N. J.," Grand View, Ind. The downy material within the pods of milk-weed or silk-weed has been used for paper making. We do not think cotton is likely to fail, or that the question of substitutes has any practical value.

Cotton from the Balm of Gilead.—"W. A. M.," Pittsburg. It is not a freak of nature, but one of her provisions for scattering the seed. It does not appear until the tree is old enough to bear seed. It would undoubtedly make good paper, and perhaps serve other economical purposes, but at present it would cost more to gather it than it would be worth. It belongs to the genus *Populus*, which also embraces the cotton wood of the western rivers, which is named from the cotton it sheds when the seed is ripe. We do not share the apprehensions of many that the southern supply of cotton is about to fail.

About Cork.—(Inquirer.) It is the outer bark of an evergreen oak, growing chiefly in the countries bordering on the Mediterranean sea. It is sometimes cultivated further north, as a curiosity. When about 15 years old, the bark is cut off in strips; and afterwards crops may be taken off every eight or ten years.

The Aquarial Gardens in Boston, —long famous as a place of public resort, have passed under the management of Mr. P. T. Barnum, who purposes to make them still more interesting and instructive.

Horse-Racing at Fairs.—A good thing to remember. In the case of a suit brought against the Monroe Co., (N. Y.) Agricultural Society, to recover a premium offered for fast horses, which suit was carried to the County Court, it was decided against the plaintiff, on the ground that "all running, trotting, or pacing of horses, for any bet or stakes, in money, goods, or other valuable things, or for any reward to be given the owner or rider, for any animal which shall excel in speed, is racing, and racing is unlawful."

Farmers' Clubs.—"E. A. H." Granby, Conn., wrote thus some time since about the farmers' club in his neighborhood. "We hold fortnightly meetings—by invitation of members, at their residences. We take our wives or daughters with us, spend the evening in discussing some question pertaining to our occupation, previously proposed—the ladies occupying the parlor with the hostess; closing early after partaking of cake, fruits, nuts, etc. We separate with parting salutations, exchanging assurances of being present at the next meeting. Although a scattered community, we collect in goodly numbers every other Wednesday evening, and enjoy a social interchange of views on some important question of agriculture or horticulture, get better acquainted, become more attached to our occupation, and to each other." This is a model club. Farmers, follow on.

Turnips—The Last Chance.

It is one of the excellencies of the turnip, that it is always in order, from May to September. We have sowed turnips as late as the 1st of the latter month, and got well paid for the labor. Any spare patch of ground, where other crops have failed, or have been removed, may be turned to good account by sowing turnip seed. Turnips come in, as a substitute, for many other crops, and a smart farmer may even now make up a deficiency in hay or grain, by the aid of turnips. And it is worthy of notice, that dry Summers, which pinch those crops, are usually followed by wet Autumns, which are very favorable to turnips. There is a special reason for making the most of this crop the present season.

The demand for grain and breadstuffs is likely to be unusually large. Not to speak of the foreign market, there will be a great demand at home. The operations of the war must have diminished the product of grains somewhat in the North, and still more in the South. With all the efforts of the Confederate Goverument to secure an increased supply of breadstuffs, at home, it is not likely that the South will produce as much grain as usual. Every plantation has felt the excitement of the times, and it is impossible, under such circumstances, to get the usual amount of labor from slaves. Our advancing armies have found destitution in many places, and there is, doubtless, much more that has not been heard of. There can not fail to be a very great demand for provisions in the Southern States, as soon as they are thrown open again to commerce. It becomes us, then, to make the most of the season that is left us, in raising all the turnips we can. The hay crop is short in many parts of the North, and turnips will save hay. They will also save grain in feeding pigs, sheep, horses, and cattle. They will make mutton and wool, beef, and pork.

The White French, and the Sweet German, or Rock Turnip, may be transplanted still. They will grow as readily as cabbage, and make a fine crop. There are yet a hundred days before the frosts will injure them. A little bone-dust, or superphosphate, will give them a start.

For broadcast sowing, in the corn and potato fields, the strap-leaf, cow-horn varieties are excellent. We have grown them at a cost of four cents a bushel, and at this price they are cheap feed for all stock that relish them. Improve all the waste patches in the field and garden with a sprinkling of turnip seed.

Washing Carriages and Wagons.

It is a great annoyance to have a nicely painted carriage scratched by careless or ignorant hands in washing it. Yet how often is this done! A broom and pail of water sometimes constitute the whole equipment; possibly, an old rag is throw in. The broom or rag is wetted, and dashed on the smooth surface of the vehicle, and the scrubbing proceeds, until the mud is washed off, and some of the varnish and paint, beside. Now, the right way of doing this is very simple. First of all, give the mud a thorough soaking with water, when water from a hose can not be used, using a common garden syringe or sprinkling-pot. Soak it again, and not a little of the mud will run off without any rubbing. With the surface thoroughly saturated, begin with a large sponge full of water, wash gently, depending still more upon the water than the rubbing. A large, soft cloth will answer, if a sponge can not be had. After the mud and grit has all been washed off, give it another sprinkling or two, and after taking off the excess of water with a soft sponge, rub the whole clean and dry with a piece of soft chamois leather. See that this is perfectly free from grit or knotty places. It will remove lint and dust, and leave the varnish clean and brilliant.

Domestic Guano.

It is an old story, we know, but one which will bear repeating, that farmers should take all possible pains to make the best use of their home manures, before buying any foreign fertilizers. Take the single item of hen-dung. It is one of the most powerful fertilizers in the world, for the reason, chiefly, that it contains the liquid and solid excrements together. Prof. Norton says: "It is found to be particularly rich in nitrogen, and also in phosphates. The manure of pigeons, hens, ducks, geese, and turkeys, is very valuable, and should be carefully collected. The amount to be obtained from these sources may be thought so insignificant as to be unworthy of notice; but it must be remembered that three or four hundred pounds of such manure, that has not been exposed to rain or sun, *is worth at least* 14 *to* 18 *loads of ordinary manure.*"

Of course, this dung should not be applied to plants in its crude, concentrated form—it would kill seeds or roots at once. The true way is to place the roosts where the droppings can be gathered up. Then sprinkle the floor beneath with charcoal-dust or gypsum. Where these are not convenient to be had, prepare a heap of dried muck, well pulverized, and spread it under the perches twice a week. Shovel and sweep up the whole mixture once a fortnight, and put the same in barrels. Pursue this plan until near planting time. Then empty your barrels on the barn-floor, and mix the heap with more plaster, ashes, or muck, so that the hen-dung will finally be about half of the mixture. Dampen the compost a little with water, cover the heap with old mats, and let it lie until wanted in the field. Apply it to corn at the rate of a gill to a hill; but be careful to cover it with a little earth before dropping the seed. Use it also at the same rate for potatoes, mixing it a little with the soil at planting. It may also be drilled in with wheat, using it, however, in almost as moderate quantities as guano. If barnyard manure is also used broadcast, ten bushels of this fertilizer will be abundant for an acre. It would richly pay any farmer or gardener to buy hen-droppings at half a dollar a bushel. Certainly it is unwise to give them away, as some do, to the tanners.

So with other home-made fertilizers. Some sort of absorbent should be kept constantly on hand, and nigh at hand, convenient for use at all seasons of the year. Dried peat or muck, coal-ashes, saw-dust, chip-manure, tan-bark,—all will answer a good purpose. Throw a little, once a week, into the privy-vault. It will keep down all unpleasant odors, save the waste of urine, and make the bulk of material double in quantity and value. When the time comes for the annual cleaning out, Patrick will not make up a wry face, at all at all. Mix the contents with as much more of common soil, and in the course of a few months, we shall have a large pile of excellent, safe and not offensive manure.

Few persons are aware how much can be accomplished in a single year by saving and using the slops of kitchen and chamber. We know of more than one man, who, on hiring a village house and garden, with the soil nearly worn out, has made it quite productive, chiefly by this simple means. One of these pursued the following course: Not being able to buy much manure, he placed a tight barrel near the kitchen door, where it could receive daily offerings from up stairs and down stairs, and weekly gifts from the wash-tub. Every night, in Summer, on returning from his shop, Mr. K. took pail and watering pot, and scattered the rich slops between his rows of cabbages, beets, potatoes, beans, etc. The rains fell often enough to dilute his liquids. In the fall, it appeared that his worn out ground yielded better than that of his fore-handed neighbors.

Our advice would be to dig a pit somewhere in the rear of the dwelling, wall it up with slabs, plank, or brick, and conduct all the slops of the house into it through a drain. Into this reservoir, cast, from week to week, all manner of absorbents. When the pit is filled, it will be worth a good deal of money. But let each man take his own way of economizing. Only, let *some* plan be pursued of saving all the refuse perishable material about a place, and converting it into manure. This is the way to fertilize land, and to feed its occupants.

Tobacco Cultivation—No. VI.

We are forced to be quite brief in our directions for the culture of tobacco. The season has arrived for the most vigilant, watchful care of the Tobacco crop. The leaves are so far matured that the worms, if they have any chance, do great damage before the owner knows it. The tops are running up, and yet are too weak to sustain high winds—as the stalks are brittle.

Topping should proceed at once, or as soon as the plants attain sufficient hight. It is difficult to lay down precise rules for topping tobacco, yet the judgment of the cultivator can hardly lead him far astray. The hight at which the flower stem is broken off depends upon the general vigor of the plant, and the size of the leaves. The size of the leaves rapidly diminishes in the Connecticut seed-leaf variety after the 12th to to the 16th leaf on thrifty plants, and such are usually topped 2, or at most 3, feet from the ground. Plants of less vigor should be topped lower;—the farmer using his judgment as to how many leaves the root will perfect. The later the season, the lower should the plants be topped, as it is the more necessary that the whole energies of the plant should be directed to maturing a few leaves.

Of course, all those various circumstances which affect the growth of tobacco, affect also the hight and time of topping. When this is done, no more leaves grow; but those left, especially the upper ones, feel the influence at once, and grow most rapidly, and if the weather is favorable, very soon ripen. Meanwhile the buds in the axils of the leaves push with almost inconceivable vigor, and must be pinched or broken out as fast as they grow, so that all the sap shall go into the leaves. As they ripen, they become turgid and brittle, with swollen veins and tissues apparently bursting with sap, very different from the soft pliability of a young and growing leaf. Tobacco growers, at the North at least, usually top their plants when the stalks begin to run up rapidly and branch, breaking them off at the 3d or 4th leaf below where it branches. This is about 2½ to 3 feet high. Remember, one frost will probably make a finish of your tobacco, therefore leave no more leaves than will ripen before frost. The leaves are very brittle, except in the heat of the day.

The Agriculturist Crop Reports.

Breadth, Present Condition, and Prospects of the Principal Crops, Gathered from 1,500 Reporters in 24 States and Territories.

Our reports for July 10th, show an exceedingly favorable condition of the crops over the whole country. There will be no failure of any of the small grains, nor does the present prospect indicate any serious falling off in the amount of the corn crop. Of course this crop depends much upon the weather of September, and the holding off of frosts. We have had so much cold weather, and the season was so late, that we have almost a right to expect a late Autumn, and good ripening time for our great cereal.

CORN.—There has been from the first some cause for anxiety in regard to this crop, but the recent hot weather has brought it up very rapidly, and reduced greatly the chances against our having a full crop. There are sections where the last year's crop is still on hand in considerable quantity, and where there has been considerable less planted than usual, but in general, where there has been any diminution in the breadth of corn, the introduction of Sorghum more than makes it good. Upon this crop depends our supplies of *Beef and Pork*, and those of our readers who have expressed their regrets that we have not included these in our statistical tables of crops will see, if they consider, that not only the *price*, but the *quantity* of pork and beef put into market, has a direct relation to the price of corn. This depends upon its abundance and the condition in which it is secured, that is, its fitness for transportation. The number of cattle or swine in any one district at any particular time, has very little to do with the supply or the price, except late in the season, when the corn crop has been chiefly converted into beef and pork, and of course, we except also the prevalence of wide-spread epidemics, which might, and in all probability would, seriously affect the market both for corn and meat.

The Corn crop of the West is represented as just about as promising as usual. In Illinois, Wisconsin, and Michigan, and some other States, there are fears of a short crop, a falling off of 10 to 20 per cent being the estimate; but in Ohio, Indiana, Minnesota, Pennsylvania, and New-England States, on the whole, the appearance indicates a full average or even above, and a little more than the average breadth planted. In New-York and New-Jersey the corn looks poorly, and is estimated at considerably less than average.

WHEAT.—The weather during the wheat harvest in the great Western States, and we may include also the Middle States, has been, up to our last accounts, prevailingly very fine, so that the crop is well secured. Throughout Ohio our reporters seem to be in a real state of ecstacy over the crop, and mark it from 20 to 300 per cent better than common, the average being about 56 per cent for the whole State.

In Indiana farmers seem to entertain very much the same feelings, and the average in this State is about 44 per cent better than common; while in Illinois it is 30 per cent. This, of course, settles the matter with regard to this crop. And although we must say, we think, in the excitement of satisfaction in so good a crop, and such fine weather, several undoubtedly have considerably over-rated the crop, and thus raised the average of our returns, still it may be put down as a considerably larger crop than usual, throughout this wheat-growing region.

SPRING WHEAT has been considerably damaged, and averages a small crop in many localities in Wisconsin, Iowa, and Minnesota, where comparatively little other wheat is grown. In Minnesota the crop is better than in the other States named, and a full crop may be anticipated, if it be well harvested. At present our reports from other districts run fully 15 per cent below a fair average. Still the breadth sown, as compared with last year, will almost, if not quite, make up the deficiency.

RYE.—The crop, so far as reported, and we have full reports of that part of the country where it is most cultivated, is fully up to average.

OATS have been affected by the rust somewhat, and in some sections injured by the aphis. The weather was unfavorable at the time of sowing and in May, which this crop never recovers from. The crop will therefore be light.

HAY AND FORAGE CROPS.—The Hay crop at the West is remarkably good, and well secured. In Pennsylvania it is represented as nearly 20 per cent above average. In New-York, however, it falls nearly as much below, and in the Eastern States about 9 or 10 per cent short of a full crop. The drouth in Northern New-York and New-England has greatly affected this crop. Many of our reporters include Hungarian grass and sowed corn with the hay crop, which is right, as they take the place of it entirely.

BARLEY.—We have reports from Ohio, Wisconsin, Michigan, Pennsylvania, Maine, New-Hampshire, and Vermont, which represent the crop hardly as favorably as last month's report, though, on the whole, better than average.

SORGHUM.—So far as we can now judge of the crops, the prospects are quite as good as usual. The average of the reports puts it about 3 per cent above a full crop. The breadth it will be remembered is two or three times that of any previous year.

FLAX is reported as remarkably good, with greatly increased breadth. The reports we have put it more than 12 per cent *better* than usual, and the amount sown at fully double.

TOBACCO.—We have few reports, but hear no complaints, except that it is a little backward.

BUCKWHEAT.—It is still too early to report much about this crop; we hope for fuller reports next month.

PEAS AND BEANS.—The demand for these for the Army and Navy has induced a much larger breadth to be sowed than common, and except where they have been injured by the drouth in northern New-England, they look very promising, averaging several per cent better than usual.

FRUITS—Still promise well, though many apples have dropped in some sections, still, more than an average crop is left.

Crop Prospects in Europe.

LONDON, *Tuesday, June 24, 1862.*

A question of much interest to farmers and many other classes, both here and in America, is the condition and prospects of the growing crops, especially of the great commercial crop, wheat. I have recently passed through the Northern part of Wales and Ireland, across the Southern part of Scotland, and about 400 miles down through the inland agricultural regions of England. During this trip, every opportunity has been availed of to learn from personal observation, and from constant inquiry of farmers, the condition of the growing crops. During the past week I have also met and conversed with many agriculturists from different parts of the Kingdom, who are drawn here by the great show of the Royal Agricultural Society. The conclusion I draw from all these sources of information is, that a much larger area of wheat was sown last Autumn than usual, at the expense of the usual area of Spring crop. But there is now much anxiety as to the effects of the continued rains. I was prepared to find much more rainy, and damp, foggy weather here than in America, but during two weeks past I have had but few glimpses of the sun, and Sunday last was the only day in which my umbrella has not been used to shed off falling rain. The crops here may have become, in a measure, "acclimated" to this daily shower bath, yet the effect of so much damp weather can not but be detrimental. All are hoping that clear skies will come in time to allow the wheat heads to set and fill out well, yet it is evident that there is much anxiety, and no one claims to hope for more than average yield, notwithstanding the large area sown. The markets are a pretty certain indication of the general feeling and expectation, and, as the commercial reports will inform you, prices of wheat and flour have been advancing here for several days. The recent advices from France and other parts of Europe, and by telegraph up to to-day, report severe rain storms in some places, and drouth in others, with a general expectation of a moderate, if not deficient, yield of wheat. The stock of old grain, at the close of the present year, will of course, be very small. I have therefore, little hesitation in predicting that there will be a continued foreign demand for American breadstuffs after the next harvest here. O. J.

Royal Agricultural Show, etc.

Since the letter from the Editor on page 236 was printed, a note from him has been received, from which we take the following extract. We find room for it here, though it might more appropriately follow the letter referred to, as a postscript: "You will see that no prize is given to the superb Short-horn Bull "*Lord Oxford*," bred by Samuel Thorne of Dutchess County, N. Y., and exhibited here by the Duke of Devonshire. In *my* opinion he is the best animal among all the splendid collection of 250 Short-horns gathered in Battersea Park as competitors for the Royal Society's prizes, and as a set-off to my national partiality, I may add that the same opinion was freely expressed by many good English judges on the fair grounds. Though in flesh enough for the purpose for which he is kept, he is not so fat and sleek as some other bulls in the same class, (those above 3½ years old). Plumpness, i. e. fatness, seems to be one of the requisites to secure success at the English as well as at many American show grounds.

The display of animals is probably the largest and best ever gathered into one place. I send herewith a summary of the entries from Great Britain."

Short-horn Cattle of all classes			250
Devon	do.	do.	66
Hereford	do.	do.	97
Ayrshire	do.	do.	70
Jersey, or Alderney	do.	do.	22
Various other breeds	do.	do.	177
			682
Horses of all kinds			285
Sheep—number of entries of all kinds			642
Pigs	do.	do.	194
			1803
Entries of Stock from the Continent			183
Total entries of all kinds			1986

[Total number of animals shown, about 2,400 or 2,500.]

PISAN BULL AND OXEN OF THE VAL DI CHIANA.

Engraved for the American Agriculturist.

We are in the habit of regarding the existence of certain "points" as essential to the value of domestic animals, according to the uses for which they are bred, whether for labor, food, milk, or wool, etc. The practised eye of a dairyman demands certain points in a dairy cow, and that they are likely to be perpetuated in her calf. The breeders of working cattle seek the development of different points from those sought where beef or milk is the especial desideratum. In England, whence we derive our notions of neat cattle, the most systematic breeding has been pursued with reference to flesh-production, breeding *out* bad points, and perfecting good ones, so far as possible. The Shorthorn has been brought very near perfection as a beef animal. The heavy neck and dewlap has disappeared; the hind quarters, especially the loin and rump, have been proportionally increased; and, in fact, the animal which we now consider so nearly perfect is very far from it, if we regard him as God made him—to take care of himself and his herd of cows, to fight their battles, and be the flock leader and master. We give above a striking picture of animals bred with great care, but not for beef. The bull, in the foreground, is of the somewhat noted Pisan breed of Tuscany,—large of stature, heavy and powerful fore quarters; hind quarters showing activity, but lacking beef qualities—evidently a bull to fight, and to work! Two such animals opposing one another would lay out a vast amount of strength, if pushing with locked horns. The whole force of the bull of such a build is concentrated in his forehead. This is most obvious when the attitude, position of head and play of muscles is observed in such an animal in the act of pushing, fighting, or laying out strength in that way. Among that macaroni-eating people, though beef is valued as food, they are content with what nature furnishes, fat in one place, and lean in another—good strong beef; the tender-loin perhaps is all the more valued because there is little of it, and the neck-pieces are probably regarded as so much clear gain over the thin necks of British cattle, while the larger the bones the more soup they will make. Work is what is wanted, and beauty of color—weight of bone, and grace of motion so far as it is not inconsistent with strength, are sought in addition. The result is the production of animals very much of the wild or uncultivated type, as any one will see from the picture. The oxen of South America, Africa, and India, have a similar look. All these wild bovine races tend to great weight in the fore quarters.

The oxen are of the large cream-colored breed of the Val di Chiana, in Tuscany. They are bred with great care, and are of a uniform color throughout, and the breed possesses similar characteristics to those just referred to, heavy fore quarters, deep brisket, full dewlap, light loin, etc. They are very powerful draught animals, fatten rapidly, and the beef is good.

These animals are broken to draw by the head, as the pad across the forehead indicates, and this is indisputably the true way for all neat cattle. The whole shape of the animals shows it; all the muscles of locomotion concentrate their power as it were in a focus at the forehead. To make them draw by the neck is a refined sort of cruelty, to which the poor beasts in this country are thoroughly accustomed, and we have no doubt that nearly half the power of the ox is wasted, as a general rule.

South-Down Sheep.

The sheep is a triple source of profit to the farmer, as mutton, as a wool-producer, and as a manure maker, not to include its value in clearing land of certain weeds and bushes, which are very difficult otherwise to eradicate, which may be fairly reckoned among the profits of sheep-culture. The value of the manure made by sheep depends upon the quality of the food; there is no difference in breeds. There are, however, great differences between breeds in regard to the quality and abundance of the wool, their rapidity of growth, and both the excellence and the quantity of their flesh. We may, therefore, raise sheep chiefly for wool, chiefly for mutton, or for both combined, and it depends upon the markets, the part of the country in which the flock is to be kept, the size of the flock, transportation, and many minor matters, which course is most profitable.

It is not our purpose now to discuss the relative advantages of various breeds, but mention this to show the true position of the South-downs. It is eminently a mutton breed, while the wool product is a source of quite as much profit, at present prices, as that of ordinary fine wool sheep. The South-downs are classified as middle-wool sheep, the fleece being neither coarse nor fine, long nor short, and it is exactly that kind for which there is the greatest present and prospective demand. Relatively the fine wools find a particularly poor market, and within the year they have sold and been used for the same purposes as wools of very much inferior grades. The weight of the fleece of a good South-down is so much greater than that of Merinos or Saxons, that the difference of no more than 10 to 15 cents in the price per pound turns the balance of profit in favor of the lower-priced wool. It is, however, as mutton sheep, in which it has no superior for quality and profit combined, that this beautiful breed has its chief claim to consideration.

The long and careful breeding of JONAS WEBB, of Babraham, England, was attended with such marked success, that it is on all hands acknowledged that he brought the mutton points of the breed very near perfection. Mr. Webb became an old man, his flock was in splendid condition, its reputation could not be higher; he had, besides, become so famous over the whole world, that it was necessary for him to entertain a great deal of company, both friends and entire strangers, and there was no one to whom he could entrust the care of his flock while he, in partial or entire retirement from business, sought that repose which he felt he needed. He therefore

offered his entire flock, except the lambs, for sale, which sale took place on the 10th of July last year, and the lambs were sold on the 20th of June, this year, and thus this worthily famous flock was dispersed.

RAM-LETTING.—The system of ram-letting has been followed with great success in England, offering, as it does, great advantages both to the owner and hirer:—To the owner, because he does not lose the services of rams, whose good points he may wish to perpetuate in his flock, while at the same time he is well paid for their services; to those who hire, because they are thus enabled not only to gain, at reasonable cost, infusion of new blood, but they may select, from among many, those possessing such points as their own flocks may be deficient in, and so, in consecutive years, very greatly improve their flocks in all desirable particulars. This system has never been pursued to any considerable extent in this country, but we are gratified to know that at the approaching sale of rams and ewes advertised by Mr. Taylor, of Holmdel, N. J., this is to be a prominent feature. Mr. T. has a number of rams of such excellent points, and of such noted parentage, that he is unwilling to offer them for sale at present, but proposes to let them for the season.

THE FARM AND FLOCK OF MR. J. C. TAYLOR.

This flock gained a wide celebrity after the Babraham sale, last year, from the fact that Mr. T. became the purchaser of several of the best animals of the herd, and particularly of one, the best ram of Mr. Webb's flock, "No. 89," for which, as we reported at the time, the great price of 260 guineas, or $1,300, was paid. It is well known that Mr. Taylor has for years been the owner of a most excellent flock of South-downs, which, year after year, he has been improving by introducing the best blood of Mr. Webb's flock. His own sales have been quietly made chiefly to California, and distant parts of the country. In fact, up to the time of his own purchase of the $1,300 ram, he had sold one for the highest price that had ever been paid for a sheep, ($1,000). We found his large flock of sheep in most excellent condition, and more than answering our expectations. There are but few which are not of the Webb South-downs, either imported animals, or their descendants, and showing great uniformity in size and general character. The sheep enjoy excellent pastures, good sheds, and careful watching and attention, but there is not the least attempt at show about the flock or the farm.

Holmdel is situated in the county of Monmouth, N. J., in the northern part of the green-sand-marl formation, and this wonderful fertilizer underlies the whole of Mr. Taylor's farm. A stream passing through it, exposes the deep beds on either bank, while a good part of the bed of the stream seems to lie in the same deposit, the very pebbles of the brook being the belemnites and shells of the marl. With this manure always at hand, in condition to be immediately applied, free from weed seed, good for any crop, and requiring no especial care in the application, it is no wonder that this portion of New-Jersey teems with fertility. We must say, however, that it leads people to neglect other manures, and the piles of corn-stalks and other material for composts, unused upon the farms, look badly to the eye schooled to regard this as evidence of negligent farming. There are a good many lambs raised here for the New-York market, and since the introduction of South-downs, and the use of bucks crossed upon common ewes, the lambs are much sought after at high prices. Mr. Taylor's neighbors, however incredulous at first, now unite in placing very high estimation upon this breed, and they would be very loth to part with the use of the rams.

The offer of several of the very choicest of his lambs, to be sold at his approaching sale—one only, which he considers the best, being reserved—is, we are sure, after seeing the stock, *bona-fide;* and we consider it due to our readers to say, that the opportunity is one the like of which has never been offered in this country to obtain sheep of this breed, and indeed better South-downs can not be bought anywhere in the world. Many sheep of Mr. Taylor's own raising are fully equal, and in some cases superior to the imported stock, except in the case of one or two of the Webb bucks, which seem as near perfection as a sheep can come. It is very interesting to compare the present perfection of the South-down with the form considered excellent in animals of this breed a few years ago, to see how the chest is deepened, the girth expanded, the loins widened, the length gained in the rump, the gain in the neck, the breadth of the back, etc. So gratified were we, that we esteem it a privilege to commend this noble breed and Mr. Taylor's sale to the attention of our readers.

"Pleuro-pneumonia," or Lung Murrain in Neat Cattle.

This disease, at present unknown at the West, with us at the East is so far *naturalized* that we believe it may break out in almost any herd situated on any important thoroughfare, or in which there are working cattle which go upon the highway. Still there is as yet but very little of it. The vigorous measures pursued in Massachusetts and other New-England States, to a certain extent checked the evil, and the existence of the disease at other points along the sea-board where ship cows have been bought, though frequently recognized, has not given rise to extensive disaster. We have no doubt the disease may be suppressed, wherever it breaks out, by the perfect isolation of the herd, and the slaughter of every animal of it; not as was done in Massachusetts, killing and burying every animal; but by putting the cattle under treatment until they are cured and fattened, when they may be slaughtered; the flesh will be good food, and the hides good leather, and no danger need be apprehended to other stock, after the barns and stalls have been thoroughly whitewashed and limed, and aired for some time. We saw the disease as it existed in Massachusetts, and were fully convinced of its intensely contagious nature. The fact that of the hundreds of cattle slaughtered in North Brookfield and vicinity, there was not a single case where the contagion could not be traced directly to the imported Dutch cow of Mr. Chenery's herd which arrived sick, is abundant evidence;—that is, directly to that cow through several others by which the disease was conveyed. And again the fact that at a certain house-moving in that town, where 24 yokes of cattle were used in one "string," one pair of these, having contracted the disease from a calf brought from the originally infected herd, though not showing it, still communicated the disease to every one of the 23 other yokes, not a single one of them all being found which did not give evidence of the murrain.

The disease exists in Brooklyn, N. Y., and in New-Jersey, and in some places on the Hudson River where cows from the distillery stables have been taken. Vigorous means need to be taken to control it. The States should act, and so should individuals. It is a great crime to sell an animal supposed to be infected, or to keep such a fact or supposition secret. We need educated veterinarians. A few are in this country; however there are hundreds of quacks to one who knows his business.

In a paper which discussed this subject in "Wilkes' Spirit of the Times," by Louis Brandt, veterinary surgeon, we find the following description, which accords well with our own observation and knowledge of the disease.

SYMPTOMS OF THE DISEASE.

"In localities in which the disease has never existed, veterinary surgeons themselves can be convinced of its presence only by dissection.

"1. The evolution of the disease, in the first period, is so secret and feverless, that only a practised eye can detect its presence. The first observable symptom is, a short, dry, weak cough, or hic-cough, generally without repetition, which, in the beginning, occurs but seldom, and then when the animal rises or is watered, but afterwards more frequently, and accompanied by great pain and effort, a remarkable crooking of the back, a stretching of the head and neck, and a quaking motion of the flanks, the cough becoming more and more hollow and dry; moreover, a slight feverish motion, frequent changes in the temperature of the horns and ears, the muzzle now dry, now moist, bristling of the hair along the back, often a greater sensitiveness when the same is pressed, and sometimes a somewhat excited pulse.

"In this period we find, on *dissection*, firm and incrassated spots of a darker red, and of various sizes upon the generally pale and flabby lungs, and afterwards an effusion of yellow lymph around them in the cellular tissue, lying between the lobes of the lungs. In this period, the disease, when properly treated, is almost always curable.

"2. In the second period, the appearances are: a feverish affliction of the whole body; an accelerated, difficult and unequal breathing, with expanded nostrils, and a violent motion of the flanks; a short, hollow, incomplete, and even suppressed cough; pain on pressing the breast behind the shoulders; continued standing with stretched head and neck, lying down only now and then, and for only a short time, and generally upon the diseased side, with the feet turned under the body, and the head and neck stretched out; reddened mucous membranes; dry muzzle; warm horns and ears; delayed, dry, ball-shaped, painful excrements; entire loss of milk.

"Dissection.—In this developed state of the disease, the affected lung appears hard, firm, enlarged, heavy, can not be inflated, sinks in water, is covered with lymph from one-half to one inch in thickness, and when cut through looks like marble. The pleura and the lungs are covered with false membranes of different thicknesses and different forms, and commonly adhesions between the lungs and the ribs have taken place. In the thorax a discharge of yellowish, cloudy water, intermixed with flakes and strings, is found in various quantities, sometimes a pailful. A suppuration seldom appears, except in case of a previous inflammation of the lungs.

"In the first period, by proper treatment, a cure can be effected with a loss of scarcely five per cent. of deaths, but, in the second, the best surgeon will scarcely succeed in curing five per cent.; whence it follows, that if the owners are unable to cure the disease themselves, they should seek competent assistance in the earliest stages. There is no infectious disease that spreads so easily as this disease of the lungs, so that those who attend to animals thus infected should not go into a healthy stable. The air which remains in the clothes is sufficient, even after an interval of several days, to spread the disease in other stables. Even the surgeon who has been in an infected stable, should not go into a healthy one, without first having himself fumigated with chlorine or tar. Horses are not liable to be infected. It is even advisable, and beneficial to the diseased animals, to put horses in the same stable, for it renders their cure so much the easier."

Breeding and Keeping Swine.

The following article is returned by the Committee to whom it was intrusted to decide upon the merits of the numerous articles received, as, on the whole, the most practical and universally applicable. The kind of swine which Mr. Henry describes is common in many parts of Pennsylvania and New-Jersey, and doubtless is the basis of the Chester County breed, which is now making an effort to become recognized as a regular breed. Whether it is really any better than any well-bred specimens of the Pennsylvania hog, we will not now discuss—but with so good a breed at hand, a farmer may be pardoned for knowing no more about the breed of his own hogs. We may with propriety here add that favorite breeds of swine with us, are the Windsor hogs, bred on Prince Albert's farm in Windsor, and the Suffolk. The former are considered an improvement on the latter, and both, with their crosses, are admirable for young pork. We like the Chester County breed for a large one, very much, but for Eastern farmers, a small, quick-maturing breed for slaughter at 8 or 9 months old, is preferable, and most profitable, for hogs grow very little in the Winter, as a general rule, unless at a very considerable expense in corn. Mr. Henry's plan of feeding his pigs a little grain all the time, so as to keep them in good, rapidly-growing condition, is particularly commendable. Keeping swine on the "root, hog or die" principle until fattening time, and then crowding them by a surfeit of corn, is very poor policy, yet extensively practised. Not less commendable is the boiling the corn, instead of giving the miller one-sixteenth of it for grinding, and then cooking it after all. We have no doubt the boiling answers every purpose. A few hours soaking would save fuel as well as better prepare the corn for digestion. As to marketing—how best to sell pork depends upon the market itself.—Ed.

[PRIZE ARTICLE.]

Rearing and Fattening Hogs.

BY GATES HENRY, SCHUYLKILL CO., PA.

The hog is well known all over the world, and is confined to no one part in particular. It belongs to the same class of animals as the elephant and rhinoceros, the thick-skinned, or Pachydermata.

The utility of the hog is in a great measure owing to its very remarkable fecundity, re-producing at one year old, and hearing from eight to ten young at a time (sometimes even more), and that twice a year. Some man-of-figures has estimated the produce of a single sow, with only six young at a time, in ten generations, to be about 6,500,000.

The hog was the animal which the Ancients sacrificed to the goddess of the harvest, Ceres.

It has been estimated that there are raised, in the United States, yearly, about forty millions of hogs, which, at $7 per head, amount to the immense sum of two hundred and eighty millions of dollars; if, then, the hog could be so improved as to raise his value one dollar a head, an immense amount of money would accrue to the interest of the farmer. As you say in your prospectus that you wish a farmer's experience with raising the hog, killing, curing, etc., in preference to his acquired knowledge of the brute, I will be candid enough to acknowledge that I do not know the breed of my own swine. They are only of moderate length, with broad, square shoulders and hams, short legs, and great depth, medium-sized heads and straight snouts.

Hardly a day passes that we do not hear the remark, "as dirty as a hog." This, I consider, a vilification of the animal which Franklin's colored servant said was the "only gentleman in England," from the fact that he was the only animal that did not work in that country; I believe that the filthy habits of the hog are in a very great measure owing to his domestication, for in this State he is cribbed up in a small pen, and is fed upon the offal of every thing—upon the most disgusting food—and is considered as much an instrument for converting filth into compost, as a source of wholesome and palatable food. He has the propensity of wallowing in the mire common to all animals of his order, but generally for the purpose of ridding himself of vermin, and of protecting his thinly covered skin from the attacks of insects. In this respect the hog is no more dirty than the elephant or the hippopotamus. No animal displays the changes arising from domestication more than the hog, which may be observed by contrasting the long-legged, wild and savage boar, with the short-chanked, docile, fat and plump Pennsylvania hog, which with difficulty walks rapidly across the confines of his narrow pen.

BREEDING AND REARING.

In selecting my breeding hogs, I always pick out the best shaped, most thriving boar pig to keep over for a breeder. For a sow I select a healthy shoat, well shaped, but thin and lank, in preference to a fat and sleek one; my reasons for this are, that the lean sow will produce more pigs, and raise them better, than one in high order—the sleek one converts all her food into fat and flesh for her own sides and back, while in the lean one it is converted into food for the young. This rule is applicable to all animals. A cow which shows every rib when in milk, will bring forth larger and better calves, and give more and better milk, than the one which always looks fat enough for the slaughter. My experience fully sustains my theory. My mode of raising hogs which are intended to be kept over, is to have them pigged about the latter part of August or first of September, and after allowing them to run with the sow from four to six weeks, confine them in a separate pen. When first taken from the sow they should be fed from six to eight times a day, or else they will fall off in flesh, and it will take them weeks to recruit. Their usual allowance, at first, should be about a pint of milk to each pig, and in order to facilitate the properly attending to them, the milk barrel should be kept standing very near the pen, from which it can be dipped with a pail with very little trouble, being replenished night and morning with fresh skimmed milk from the dairy. The quantity for each pig should be gradually increased each day according to the growth of the pigs, until they have attained to the age of three or four months, when a regular allowance should be made them; and the number of times feeding may be diminished. At this time in the pig's life a little grain fed night and morning, will not be thrown away on him; a little oats or rye if the pig is in a healthy condition, followed by about a pint of corn, which may be subsequently increased to a quart. This addition of grain will tell amazingly in the growth of the animal, as well as have a tendency to keep him in such a condition, that when "fattening time" arrives he will be ready for the knife much sooner than a hog fed only on slops without the daily quota of corn, to say nothing of the saving of a good deal more corn than has been used up to this time in the feeding. The milk from the dairy, when weakened by the slops from the kitchen, should occasionally through the week be enriched by the addition of rye bran.

STY AND BEDDING.

There is no greater mistake made by farmers than allowing swine to run about out of the pen. To say nothing of the immense destruction which they are liable to do, they so completely run themselves down that it takes almost double the amount of feeding to get them in condition for butchering.

The pen in which hogs are kept should consist of two apartments—a covered and an uncovered one. An excellent manner in which to construct a pig-sty, is to erect a two-story frame building, having a part of the under story boarded off for a place in which to keep the slop barrel, reserving the rest for a dry pen for the hogs, and have a pen constructed outside, and communicating with this covered one. The feeding trough should be in the outside pen. In this manner, if the pigs are given a sufficiency of rye straw in the inside pen, and the outside one is kept well supplied with the huts of a pig-sty, is to erect a two-story frame building, having a part of the under story boarded off for a place in which to keep the slop barrel, reserving the rest for a dry pen for the hogs, and have a pen constructed outside, and communicating with this covered one. The feeding trough should be in the outside pen. In this manner, if the pigs are given a sufficiency of rye straw in the inside pen, and the outside one is kept well supplied with the huts of corn stalks, they will not only make an immense amount of manure, but will keep themselves white and clean, thus refuting the assertion of the filthiness which is continually flung at them. In the upper part of this pen should be kept litter for the bedding for the hogs; or a part of it may be partitioned off for a hennery.

I have adopted what I consider a very good as well as economical plan of getting the upper part of my hog building filled with good littering material. It is this: When hauling in my corn fodder I cut off about two feet of the hard, dry buts, which the cattle can not eat, and have them bound into small bundles and stowed away in the upper portion of the hog-house, to be used as required. These corn buts when thrown into the outside pen are so torn and trampled up that they are converted into good, lasting manure, which has not its superior on the farm, and which would be almost entirely lost if fed to the cattle in the fields, etc.

FATTENING.

When fattening time comes, I generally commence by feeding the "nubbins," and after two or three weeks, follow them up with shelled corn. This I always feed boiled, boiling in the morning what is required during the day, and at night what is necessary for the morning. Feeding thus, brings my work nearly all in daylight. In this way I can make my hogs fat enough for all practical purposes, by feeding them from fifteen to twenty bushels of corn, each, and in slaughtering at sixteen months old, they weigh from four to five hundred pounds. I never like them to exceed the latter figure in weight, for I have no fancy for this overgrown and spongy pork of forced hogs.

HEALTH AND DISEASE.

You will observe that I do not particularize any disease or its remedy—the reason is that I know nothing about disease in hogs. I have never had occasion to know—taking care of my hogs, feeding them regularly and paying attention to their litter and quality of feed. In nine years' experience in hog raising, I have had but one die—and that one I am constrained to think was bodily injured, as he became so weak in the hind-quarters that he was unable to support that portion of his body, and died while in very good condition, showing no symptoms of disease.

KILLING AND CURING.

As to the killing of hogs, I presume that almost every farmer in the land knows as much as I do; at least, every one should. The butchering is a small matter—the work of a day—and I do not deem it necessary to insert my mode here, as all have nearly the same way of accomplishing this end. The way in which to realize the most money out of the hog meat is to cut every available scrap into sausage meat, and boil the rest into scrapple (curing only the hams), and selling it while fresh, and the sooner the better, as both sausage and scrapple command a higher price early in the winter than at any other season.

The curing of pork is, perhaps, one of the most important matters in connection with the rearing of swine, and my mode I consider as one of the very best, from the fact that it never fails.

After the meat (hams or shoulders) is thoroughly cold, cut and trim the hams very close, then rub them well with salt, pack close in a barrel or tub, and after laying for three or four days, make a brine of the following ingredients: To every 100 pounds of ham, allow 4 gallons of water, 9 pounds of salt, 4 pounds of sugar, 4 ounces saltpeter, and 1 ounce saltertus. The brine should be boiled and the scum taken off; when cold pour it on the meat. From four to six weeks should be allowed, (according to size of hams), for the meat to remain in pickle. After the meat is hung up, allow two or three days to dry, then smoke with as little fire as possible. Use green hickory, with sassafras in small quantities. As soon as the meat is sufficiently smoked, each ham should be taken down and carefully wrapped in paper, then bagged to prevent the depredations of flies, and hung in a cool dry place, out of the reach of rats and mice.

The foregoing embraces only the knowledge, notings, and experience of a practical farmer, about the hog. My object will be attained, if it shall prove to be of any benefit to any one.

INTERNATIONAL EXHIBITION BUILDING OF 1862.

Engraved for the American Agriculturist.

The immense structure in which the World's Fair of 1862 is held, is in South Kensington, London. It is built of brick, iron and glass, and roofed with wood, covered with felt, and furnished with sky-lights. The galleries, as they are called, extend over nearly the whole building, except the nave and transepts and domes. Our view presents the Eastern end; and the Western end is like it, having also just such a dome. These domes are of immense size, larger than the great dome of Saint Peter's church in Rome, being each 160 feet in diameter, and 250 feet high, while St. Peter's is only 130 feet in diameter, and 263 feet high. They are constructed of glass and iron, and must resemble considerably the beautiful dome of the World's Fair building in New-York in 1853. The domes stand nearly 1000 feet apart, and are connected by the *nave* which is like the body of a church, 85 feet wide and 100 feet high, and 1200 feet long. At each extremity the nave is crossed by a *transept* 700 feet long, by 85 feet wide, and 100 feet high, the domes standing at the intersection of the nave and transepts. The long front presented in the engraving is that of the eastern transept. The long southern front on the left of the picture is 1200 feet long, and the entire space between it and the nave is covered; as is also a nearly similar space on the northern side of the nave. The whole area covered is about 15 acres, and the space occupied for exhibition purposes, 1,300,000 feet, exclusive of the temporary building, 800 feet by 200, erected on the northwestern corner for machinery, etc.

It is said there are 600 miles of floor-plank used, partly 6 inches and partly 7 inches wide, and many other curious statements are made. This immense building is well filled in nearly every department, and the managers have been obliged to exclude a vast number of articles, particularly in the British part of the exhibition. Had all the applicants for space from England alone, applying before Dec. 1st, been allowed all the space they wanted, it is said they alone would have required a space nearly three times as large as the entire structure.

The garden and show grounds of the Royal Horticultural Society are directly in the rear of this building on the north. The Show of the Royal Agricultural Society, however, is considerably removed, being at Battersea Park, on the other side of the Thames River.

Editorial Correspondence.

ROYAL AGRICULTURAL SOCIETY'S SHOW—HINTS, ETC.

LONDON, ENG., *Tuesday Evening, June* 24, 1862.

One of the leading attractions which brought me across the Atlantic, and one which has drawn together here a large concourse of agriculturists, not only from all parts of Great Britain, but from the Continent of Europe also, is the great meeting of the "Royal Agricultural Society," held this year in London. In consideration of the fact that the "International Exhibition," or "World's Fair," would concentrate here an unusual number of visitors, the Managers of the Royal Agricultural Society have made strenuous efforts to get up a Show on a scale far surpassing all previous ones in completeness and magnitude. They have succeeded admirably, but I suspect from what I can see thus far, that they are likely to be disappointed in the returns to be received from tickets of admission. It would seem as if one such attraction as the "International Exhibition" really is, would be quite enough in one season, even for the City of London. It is too early yet, however, to judge how far the Agricultural Show will be overshadowed by that of art and manufacture.

I have only time before the closing of the trans-Atlantic mail, to note a few things—those which may afford hints to the managers of our own Agricultural Societies. The present policy of the Royal Society, is to concentrate upon only one Department of industry annually. Thus: (1) one year prizes are offered only for implements for preparing the soil. (2) The next year the prizes are for harvesting implements, (3) and the third year for implements used in preparing the grain for market, and in fitting it for feeding. Last year the first class was on trial. This year the prizes are given only to animals. But though prizes are not offered, all varieties of implements and agricultural products are invited for exhibition. The appearance of the grounds to-day shows that prizes are not needed to call out exhibitors. The entries in the Implement Department alone exceed 5,000! The display is very fine, including every thing that can be used on the farm, in the orchard and garden, and in the farmer's household, from a mousetrap to the ponderous steam plow. The Show grounds cover over 20 well packed acres, about half of which are occupied by covered stalls for farm animals. The latter are separately enclosed, and no one not directly employed about the animals has yet been admitted. I have not myself "professionally" visited this enclosure, and can therefore say nothing of it, beyond the fact that there are, for the animals alone, *twenty five* canvas-roofed rows of sheds, each nearly 500 feet in length, and I learn that they are pretty well filled with animals. The judges, in three sets for each class of animals, have been at work all day, and to-morrow the public are invited in at a pound sterling (about $5) each, to see the animals and hear the awards. The daily admission to the implement yards alone, for all of this week, is 2s. 6d. (about 63 cents)—a price which, with us, would be considered extravagant for seeing the whole show. Thursday the admission to the whole ground is to be 5s. (about $1.25); on Friday and

Saturday 2s. 6d., and the first three days of next week 1s. (about 25 cents).

The system and order everywhere visible in the implement department is admirable and worthy of general imitation. A separate division is allotted for machinery in motion, and here I find about twenty farm steam engines all in operation. The field trial is twenty miles distant, where there are a dozen steam plows and steam cultivators to be tested on Thursday, Friday, and Saturday. Within the main enclosure are 16 canvas tents, each from 450 to 500 feet long, and these are filled up with an infinite variety of implements of every conceivable kind. Some of them are new, and not yet familiar to American cultivators, but not a few of these implements are the result of Yankee inventions. Every article exhibited is required to have its retail price plainly affixed. The entries were closed nearly two months in advance, which left ample time to arrange each article or group of articles in good order, and in appropriate places. It also allowed the printing of a complete catalogue of every thing exhibited, and its exact place on the ground. This catalogue also contains a brief description of the articles, in from one to twelve (12) lines. Six lines are printed without expense, but each line above six is charged for at the rate of two shillings (½ dollar) per line. The catalogue, though containg 450 pages, is furnished at a shilling. It gives an engraved diagram of the whole exhibition ground, the number of the tent, etc., so that any one having it can go directly to any article he may wish to examine. It will be well for the managers of our exhibitions to adopt a similar method. A book or pamphlet of entries allowing each exhibitor to set forth the peculiar merits of his implements or other products, in a limited space at a specified rate per line, would afford a handsome revenue, and be advantageous to both exhibitors and visitors. I have not time to further describe the agricultural exhibition, which is, beyond comparison, the largest and best arranged agricultural show yet produced. I expect to gather very many hints which will, I trust, be useful to our readers, in the future.

O. J.

Awards at the Royal Agr. Show, (Eng.,) July 2, 1863.

SHORT-HORNS.

I.—Bulls over 3 and under 6 years old: 1st prize, $150, to "Lord Adolphus," sired by Mr. Booth's Cardigan (12,556), dam, Lady Annabella, bred by John Wood, Darlington, Yorkshire.—2d prize, $75, to "Lord of the Harem" (16,420), sire, Duke of Buckingham (14,428), dam, Grand Turk, shown by J. H. Langston, M. P., of Chipping Norton.

II.—Bulls over 2 and under 3 years old: 1st prize, $150 to "Perth," sire, Prince Alfred (13,494), dam, Rowena, shown by Wm. Stirling, M.P., of Kier, Dunblane.—2d prize $75, to "Sinemester," (white), sire, Prince Victor (12,944), dam, Griselda, shown by Henry Ambler, of Watkinson Hall, Halifax, Yorkshire.—3d prize, $25, to "Great Seal" (red) sire, Lord Privy Seal (16,444), dam, Jenny Grost, shown by A. J. Balfour of Whittingham.

III.—Bulls over 1 and under 2 years old: 1st prize, $125, to "Wilmer-in," (roan), (19,179), sire, Cock of the Walk (15,782), dam, Annie, bred and shown by Stewart Majoribanks, of Waterford, Herts.—2d best, $75, to "Royal Butterfly" sire, Royal Butterfly, dam, Sweetheart.

IV.—Bull calves above 6 and under 13 month's old: 1st prize, $75, to calf shown by Jonas Webb, Babraham.

V.—Cows above 3 years: 1st prize, $100, to R. Booth, North Allerton.—2d prize, $50, to Lady Pigot, New Market.—3d prize, $25, to Jonas Webb, Babraham.

Among the owners of winning animals in other classes of Short-horns are: Duke of Montrose, Glasgow; J. Lane, Cirencester; Lord Feversham, J. Douglass, R. Booth, Lt. Col. Towneley, T. Atherton, R. R. Middleboro, J. Robinson, Lady Pigot. Jonas Webb received a gold medal as the owner of the best male animal among the Short-horns, and R. Booth, North Allerton, the same for the best female animal in the Short-horn classes.

HEREFORDS.

The first prizes in the four classes of bulls go to Hon. Col. Hood of Windsor Park, R. Hill of Shrewsbury, J. Taylor and C. Yeves of Leominster, respectively.

The first prizes in the 4 classes of cows and heifers go to H. Coate of Sherborne, J. M. Read of Cheltenham, Hon. Col. Hood, J. Baldwin of Stratford-on-Avon.

Richard Hill of Shrewsbury, is the recipient of the medal for the best male animal, and H. Coate, of Sherborne, received the medal for the best female.

DEVONS.

First prize for best bull over 3 and under 6 years, was awarded to James Davy of North Molton; do. for best bull over 2 and under 3, to W. Farthing of Bridgewater; do. for best yearling bull, to Hon. Col. Hood of Windsor Park; do. for best bull calf also to Col. Hood: do. for best cow over 3 years, to James Davy of North Molton; do. for best heifer, in milk or in calf, under 3 years, to W. Paull of Piddletown; do. for best yearling heifer, to Jas. Davy of North Molton; do. for best heifer calf from 6 to 12 months old, to J. Davy of North Molton.

Gold medal for best male animal was awarded to Jas. Davy of North Molton; and for best female to the same.

JERSEYS OR ALDERNEYS.—The owners of first prize bulls are D. Smith of Bainstoke, R. Watts of St. Heliers, Jersey; and first prize cows, etc., are owned by F. Newman, J. Pye, of Stamford Hill; A. Le Gallais, St. Aubins, Jersey, whose cattle also received one 3d prize, and several high commendations.

AYRSHIRES.—In the four classes of bulls, the first premiums go to the Duke of Hamilton and Brandon, J. Stewart of Strathaven, in 2d and 3d classes, and the Duke of Athole of Dunkeld. The three first premium cows and heifers are owned by the Duke of Hamilton and Brandon, in 1st class, and J. Stewart in 2d and 3d classes.

SUSSEX.—Prizes are awarded in three classes of each breed, *viz*: I. Shearling ram. II. Ram of any other age. III. Five Shearling ewes. The following are the names of the owners of 1st prize animals of some of the breeds most valued in America:

Leicesters.—W. Sandy of Holme Pierrepont sweeps all the prizes given to this breed, except the 2nd in the first class, and takes a gold medal for the best Leicester ram.

Cotswolds.—W. Garne, Bibury; W. Lane, Northleach, in 2d and 3d classes.

South-downs.—Earl of Radnor, Highworth; W. Rigden, Brighton; Sir R. G. Throckmorton, Carrington.

Cheviots.—T. Brydon, Moffat; W. G. Hunter, Langholme; T. C. Borthwick, Langholme; R. Borland, Closeburn.

Preparing for Wheat.

The time has been when, throghout all the Atlantic States, there was no need of manuring the soil for grain crops. The rich, virgin lands contained all the necessary elements for their growth and maturity. This is true now, to a greater or lesser extent, at the West. But elsewhere it is otherwise. The dung-cart must precede the reaper, or the latter will gather only scanty sheaves. There is little reason to fear that the plants will expend all their force in producing stalks, at the expense of well rounded grain, or that the crop will lodge and mildew. We must make our soils warm and mellow, and get a quick, vigorous growth and early maturity, else the midge will follow hard after the crop and destroy it. From five to ten days in the time of maturing the crop, generally decides whether or no it will become the prey of the midge or rust.

What does science teach us in reference to the needs of our soil? Prof. Norton says: "The grain of wheat contains from 50 to 70 per cent of starch, from 10 to 20 of gluten, and from 3 to 5, of fatty matter." It would seem that wheat contains more nitrogenous substances than any other grain. A careful writer on this subject says: "Up to the formation of the kernels, ordinary soils, with rain, dew and air, can furnish and grow the wheat plant. But when it comes to the fruiting part, the plant has to seek in the soil for materials out of which to fabricate its seed. It is necessary, therefore, that there be in such soil what we farmers call nutritive or purescent manure—something out of which *nitrogen* can be formed." In barn-yard manure, and other fertilizers of similar character, we find this important element.

Every farmer who intends to sow wheat in the Autumn, should preserve a large lot of his Spring supply of manure to put in with his grain. Increase the pile in every possible way, during the Summer. Compost it with sods, half-rotted leaves, or straw and other litter, and in a few months the heap will have doubled its size and also its value. This stack being worked over will be in a half-decomposed state by sowing time, and thus will be in just the best condition for nourishing the young crop.

The common practice of manuring for corn in the Spring, and then following this with wheat without any more manure, may answer on some strong and rich lands; but otherwise, a fresh and abundant supply should be given before sowing. Some of our sagacious farmers apply a barrel of salt per acre to their wheat lands, a short time before seeding, and find the result every way satisfactory.

That early and hardy varieties of wheat—such as the Mediterranean and Golden Drop—should be chosen for seed, where experience does not assure the success of other kinds; the land well drained, and the sowing done early, are points so manifest they need no urging.

Top-Dressing Mowing Land.

The cutting of grass for hay is an artificial process, and must do more or less damage to the roots. It stops the growth of the plant in its greatest luxuriance, and removes the shade from the roots at the season when they most need it. If the weather is dry they remain exposed to the burning sun for weeks. Timothy, especially, is a long time in sending up new shoots, and is often killed outright by close mowing. The bulbs dry up, and it is quite likely that winter-killing gets the blame for injury done by the scythe in Summer. In pasturing land the grass is removed very gradually, and it is at no time bare. Good land not fed too close, will remain in grass, giving remunerative crops for a century. But mowing lands, as they are generally managed, need to be re-seeded every fourth or fifth year. Where a rotation is followed this may be the wisest course. But a farmer often has some lots that he would like to keep in meadow continually. He may do this by top-dressing immediately after mowing. This is especially desirable with lands seeded to timothy. From several experiments we believe this to be the best time to apply a well made compost, or any coarse manure, and should always attend to it now, if the haying were not so pressing. But with mowing machines and horse-rakes, farmers can accomplish much more than was possible twenty years ago. The manure acts as a mulch to the roots of the grass immediately. It makes the most of every rain and dew that falls, and soon changes the bare meadow to a green field. The aftermath is much more luxuriant, and we get, in the increased burden of grass, a return for the manure within two months of its application. We believe meadow land may be kept up to a yield of three tuns to the acre, by the annual application of compost as soon as the grass is cut.

We have before us a strip of meadow manured at this time two years since, and another by its side treated in the ordinary way, i.e., mowed and left to take care of itself. The one has a promising growth of timothy, and upon the other this grass and the red-top have mostly given place to sorrel. We know of no reason for the difference except the top-dressing in July 1860. We never apply manure to meadow land, more or less, at all seasons, but manage to have a good supply for the land as soon as the hay crop is gathered. By this course, we expect to keep some fields in grass perpctually, with no falling off in the yield.

A Connecticut farmer, recently speaking of the very great value of seaweed, particularly rockweed, told us he had employed an old man with an old horse to draw rockweed last year, and spread it daily upon mowings, from August to November. The loads were small. A very great good effect was seen, but most markedly by far, where the application was made earliest in the season—equally shown in the first crop and in the aftermath this year.

Weeds.

"Slack never thy weeding, for dearth nor for cheap,
The corn shall reward it, ere ever ye reap;
And especially where ye do trust for to seed,
Let that be well used, the better to speed."

Old Tusser uttered many pithy sayings in his rude rhymes, doctrines as sound to-day as when they were uttered. We have now reached a season when many are accustomed to slacken their weeding, and thus lose much that has been gained by the clean tillage of the first part of the season. The corn is laid by, and the potatoes, and weeds grow apace even in the shade of the crops. They go to seed, and completely stock the ground, making work for future years. It is a busy season of the year, and it is thought that labor will pay better somewhere else, than in subduing these pests of the farm. We have seen corn fields well manured, and otherwise well managed, so matted with grass and weeds, that there would be a loss of thirty per cent. on the yield. We have seen oat-stubble, and other fields stocked to grass, so overgrown with weeds that the young grass was choked, and made so feeble that it could not withstand the Winter frosts. We have seen pastures overgrown with Canada thistles, briars, and shrubs, so that they would not yield half a crop of grass, and this of inferior quality.

What is to be done with our August weeds? It is of course too late to cultivate potato fields, as that would lead to the setting of small tubers. Some varieties are already dug, and others soon will be. All sorts, if planted early, would mature by the last of this month, and then the weeds might be turned under by the plow before they have time to seed. One of the advantages of a second crop is, that it makes clean work with the weeds. Turnips, beets, carrots, and all the late crops require cultivation, until it is too late for weeds to seed. Even if the ground lies idle, it will pay to turn in the weeds. Suppose it costs $2 an acre, that is cheaper than to do $4 worth of extra weeding next season.

Corn is frequently cultivated this month, for the third or fourth time, and when the rows are wide enough, and the corn is not too forward, the horse should be kept moving between the rows. If this is not practicable, we can still pass between the rows with the hand-hoe, and cut up the few weeds that have started since the last cultivation. It is cheering to see a piece of corn having the whole strength of the soil, not a weed standing among it. This, if the crop is otherwise well treated, fills out the eob to the end, and handsomely caps it. Cultivation is, to a certain extent, a substitute for manure, and with a plenty of this article, secures maximum crops. Few weeds will be found where corn grows at the rate of ninety bushels to the acre.

There is no better month than this to kill Canada thistles, brush, and briars, that infest pastures. Cut, pile, and burn, without regard to the phase of the moon. Whatever quarter that orb may be in, give no quarter to these pests. There is no economy in cutting down expenses by refusing to cut weeds and brush. Bush scythes would be cheap if they cost their weight in gold. Joe Stubbs has twenty acres of pasture capable of feeding as many head of cattle. One half the area is covered with briars, alders, elders, hard-hack, and Canada thistles. He can only pasture six cows and a horse there, and they are not very well fed. Joe is afraid of the bush scythe in dog-days. It is lonesome work. He is losing at least a hundred dollars a year for the want of it. It would not be lonesome to see twenty head of cattle in there, with no brush to hide them. Elbow grease is very efficacious in subduing weeds, and its use is good economy. JONATHAN.

Choosing a Building Site.

With some persons, the range of choice is very limited. If they are men of business, they must live quite near the shop, store, or office; if they are farmers, they must build the house near the center of their land, or where most convenient to carry on the farm work. But with others, the case is different; and it is to them chiefly that we now make the following suggestions:

I. One thing to be considered in choosing a site, is its *accessibility*. Persons of a poetical or romantic turn of mind might choose to live perched on a high and wooded hill, remote from the common thoroughfares of men. But sober people would inquire, how are we to get to the house in dark nights, in muddy weather, and in winter? How are we to draw the hay and the wood, and other useful truck? Will it be convenient for our neighbors and friends to visit us, and for us to get to them? Strong as may be our attachments, if it is difficult for us to reach our friends, or for them to get to us, it will place a formidable barrier between us; our visits will be infrequent, and our attachments will gradually abate. The post-office, the church, railway station, stage office, and the store are institutions which men can not well get along without, now-a-days. Let us have an eye to these things, before laying the corner-stones of our permanent dwellings. Crossing many bridges, struggling through muddy roads, or toiling up and down hills, all interfere with accessibility, and should be avoided, if possible.

II. The *surroundings* of a site should be considered. Who, unless he be the smithy himself, owner and proprietor, would want to build a house with the smoke and dirt of a forge just under his windows? Cattle-sheds, pig-stys, a slovenly neighbor's out-houses, any kind of building used for manufacturing purposes, a slaughter-house, a quagmire,—in short, any thing and every thing in the line of nuisances ought to be avoided. One may think, perhaps, that custom will reconcile him to almost any thing; but not so, if he or his family are persons of sensibility. Whoever builds in the neighborhood of a nuisance will find it a source of continual mortification and regret, and will be quite sure, ere long, to sell out his property at considerable sacrifice.

In some places, a number of persons club together and buy a tract of land for building-sites, entering into a written contract that neither they nor their heirs or assigns shall use the land for other purposes than for residences and gardens. At Llewellyn Park, in Orange, New-Jersey, a similar plan has been adopted. A large tract of land is owned by a corporation, who offer building sites for sale on condition that the houses put up shall be of a respectable character, and shall have nothing in their appurtenances to offend good taste.

A small annual tax is assessed upon the lot-owners to meet the expense of keeping the roads, fences, etc., of the Park in repair. In such an arrangement, it would seem that one might enjoy the elegancies of a refined rural home in the midst of a handsome landed estate, without the expense and trouble of taking care of more than the small spot immediately around his own door, and perhaps the garden in the rear.

III. The *healthfulness* of a site is an important matter. One would hardly wish to build on the edge of a marsh, or of any standing water, unless he is proof against malaria. Then, there are some situations where the wind sweeps violently through gorges, or up and down long valleys, which are alike unhealthy and disagreeable. Low grounds generally are subject to dampness in Summer, and to extreme cold in Winter. But in avoiding low grounds, let us not go to the other extreme of pitching our tent on a high and bleak hill. A site moderately raised above low flats, yet not on the hill-top, is ordinarily the most salubrious, as it is the most pleasant. Such sites afford pure air, pure water, good drainage, and cheerful prospects, all of which are conducive to health and happiness.

IV. The *nature of the soil* should be looked to. Whoever builds in the country, builds there principally for the sake of having a little farm or garden and orchard, and ornamental trees. But these will not succeed well on a rocky bluff, a sandy plain, or a bed of clay. Is the soil good for farming purposes? Will it grow corn and potatoes well? If so, then an important question is settled. For, if it will raise these, it will raise magnolias, pears, grapes, wheat, and whatever else one has a mind to cultivate. If the soil is poor to start with, time and money, and a great deal of patience, will improve it; but the process will be very laborious.

V. Any improvements already made upon a site should have considerable weight in determining one's choice. An orchard, not too old and scraggy, a few good shade trees of large size, any amount of grading, draining, manuring, fencing, etc., that may have been done, is only so much time saved, and so much money invested for the buyer's benefit. Pleasant as it is to create one's homestead wholly, yet life is short, and it is quite a help to have a few things already created to one's hand.

We might add other hints, but these are all that our crowded columns will now admit. To all contemplating building dwelling houses, we say, think *twice* before you build once.

Spontaneous Vegetation.

To the Editor of the American Agriculturist.

"Now, did this vegetation spring from an original principle in the soil, or from seeds, perhaps a thousand years old, buried in that hill? How came they there? Did the fire beget them?"

The foregoing "nuts" of SCHOLASTICUS, in the June No. of the *American Agriculturist*, may not, after all, prove to be as hard-shelled as some imagine. I am rather of the opinion that a little impression may be made upon some of them, by striking them in the right way. It is well known that the seeds of many plants will retain their vitality for an indefinite length of time, in favorable situations. I saw an account not long since, of seeds being found with an Egyptian mummy, that had remained for *thousands* of years entombed with the body, which readily germinated, on being planted in suitable soil. After the burning of the timber of an old "girdling," in my immediate vicinity, "multitudes of a cruciferous plant," (the *Brassica rapa*) were found growing, in some of the beds of the burned logheaps, which excited the wonder and astonishment of the whole neighborhood. It was at length ascertained that the part where the *rapa* was growing in such quantity, had, about twenty years previous, been a "turnip-patch." The seeds of numerous plants, as every body knows, require a very great amount of heat to make them sprout. Some, for this purpose,

pour boiling water on onion seed. The vitality of some seeds is preserved by water. The bulblets of the *Lemna* (Duckweed), always remain from Autumn until Spring, in the bottom of shallow ponds, and if carried into deep water, and then should sink below the warming influence of the sun's rays, instead of rising to the surface and germinating, *might* remain for years, and still retain their vitality. The *Isnardia palustris*, an aquatic, growing in the bottom of streams of water, will flourish equally well if the stream happens to change its course and leaves the plant on dry ground. The *Hibiscus moschentos* I have frequently transplanted from the borders of lake Erie into dry ground, and it has uniformly flourished as well as in its native marsh. And so of scores of other plants.

We *know* that *seeds* will produce plants. It has been demonstrated ten thousand times before our eyes. But that they have ever been produced in any other way, since the formation of the first specimens, described by Moses as the third day's work of the Creation, *I* have no evidence for believing. To depend upon an "original principle in the soil" for a crop of weeds even, I should consider a very uncertain affair. I sow the seed, believing, with Paul, (II. Cor. xii. 28) that "God giveth to every *seed* his (its) own body." But if the soil produces plants without seeds, it can be proved. Institute a thorough examination, with magnifying glasses of high power, when the *thing* first starts into being. Trace it down to the "center of motion," and if there is absolutely no cotyledon, none of the essential organs of a seed, *then* write under the examination Q. E. D. DISCIPULUS.

Little Mountain, Ohio, June 1862

Tim Bunker on the Cost of Pride.

"Father, have you seen the *Agriculturist?*" asked Sally, as she handed her second baby to her mother and the paper to me. I had been to the post-office that afternoon, and had not had a chance to look at it, even if I had been in the house long enough to do it. This is generally the way; the women have the first cut. I have known Mrs. Bunker to leave a batch of dough she was mixing to read the paper, and that I guess is about the last thing a house-keeper ought to leave, especially if the yeast is good.

You see it so happened that Sally and her children came over from Shadtown that afternoon, to make us a little visit. She has always been good about coming home, and since John has been gone to the war we have seen more of her than usual, which is very thoughtful in her.

"Well no, I haven't. What is in the wind now?"

"Just read what a Western Farmer says about your taking lessons in spelling. You see you get great credit for my correcting your letters?"

"Credit, girl! The man is poking fun at me for writing out of character. I knew it would come to this, if you and the printers didn't let my spelling alone."

I have never told the public what lots of trouble I have about these letters, being a modest man, and not caring to push my private matters into notice. Folks are so awful proud now-a-days that everything has to be fixed up before it can show itself, from a baby's dress to a President's proclamation. They even find fault with Lincoln's State papers, because the rhetoric isn't quite tall enough, and the grammar don't always break joints. I'm expecting nothing else but they'll get out a new edition of the catechism, and our children will be taught "The chief end of man is to fix up."

You see in the first place I didn't want to write at all, considering that I understood the use of a plow enuff sight better than the use of the pen, and remembering that old saw "Let the cobbler stick to his last." I still think there is wisdom in that saying. But you see the editor thought I had better write, that I ought not to hide my light under a bushel, and all that sort of thing. He was very civil in his compliments, and what was I that I should set up for knowing more than an editor, and the editor of the *Agriculturist*, too? I thought he ought to know what sort of talk would edify farmers, and I didn't pretend to be any thing else. So I promised him that I would write for one year, and have kept on ever since.

Then Mrs. Bunker didn't want me to write; 'twould make a public man of me, and folks would come to stare round the house, as if they expected to see a lion in his cage; lionizing I believe she called it, and I suppose that was about what she meant.

Then Sally put in agin' my writing; said she should be ashamed to have my letters to her printed, because the spelling was awful. She admitted the sense was good enuff, about equal to any thing they had in boarding school, but the grammar and the spelling wanted fixing. So I had to tell her if the spelling didn't suit her, she might fix it to suit herself. For my part I couldn't see why it wasn't just as well to spell words as they sounded, as to follow the dictionary. I thought plow was about the same tool, whether they spelt it with a *w* or *ugh* at the end; one was considerable shorter than the other, and would save ink; besides, every body would know what I meant, and that was the end of talking or writing, to be understood. But I couldn't convince her by any common sense arguments, that my spelling was good enuff.

So "Western Farmer," and the public will see that my ideas have to go through about as much grinding and fixing before they come to light, as a bag of wheat does before it comes on to the table in the shape of bread. Sally must have her say, and the editor his, and the printer puts in the stops and pauses; so that by the time my ideas get back to me in the paper, I don't hardly know them. Some of them look as if they had been to college, and some to boarding school, and some brought up on a farm. But I take it the sense is understood, which is the chief thing.

There is one thing I don't exactly understand, why they should put in what Jake Frink says, and Uncle Jonathan, and the rest of them, just as I write it, and practice their fixing up on me. I talk for all the world just like Seth Twiggs, but Sally says that is the vernacular, and don't look well in print. Perhaps it don't. Tastes differ. I don't think it pays for altering. In my opinion Sally had better mind her babies than to be tinkering with my spelling, and I guess the public would understand my writings quite as well if the printer didn't spend so much time on the commas and exclamation points. Why, any fool would know when a question was asked, without the sign. They say they keep a fellow in the printing office at about $3 a day, just to tend to this kind of tinkering. I don't think it pays; but that is none of my business.

This pride shows itself everywhere, and is about as troublesome on the farm as in the city. I am afraid it will be the ruin of the nation yet. It seems to grow worse the longer I live. It costs me a great deal more to live than it did my father, and if John ever gets back alive from the war, he will never be able to live in the simple way I have done. Pride costs more than all other necessary family expenses. It has made many a man a bankrupt, and it keeps a good many of my neighbors poor. Every thing they earn is spent upon their backs, or upon ornamenting and fixing up their houses and farms. Farming is a good business, and pays all decent demands upon it, but it will not support much pride. A fence that costs a dollar a rod will turn cattle just as well as a faced wall of hewn stone, costing twenty times as much. The nineteen dollars extra goes to the support of pride, and farming ought not to be expected to foot the bills. A barn that will shelter hay and cattle, is just as good as one costing four times as much, finished as elegantly as a dwelling. Farming will not pay for the clapboards, the lath and plastering, the ceiling and varnish. If a man has made a fortune in trade, there is no objection to his building a country seat, and living like a prince. His profits will support his pride. But the profits of ordinary farming will not justify a like expenditure. He may keep, if he will, a servant to each member of his family, but a farmer must serve himself. When he gets above his business he had better leave it. It strikes me that a farmer's pride ought to run to his business, rather than to his walls, and buildings. Other folks have to have dwellings, barns and fences, and it is no great shakes to own good lumber and paint. But farmers only have a deep rich soil, fine wheat and corn fields, and luxuriant meadows. It will pay for a farmer to cure a horse-pond, to drain a swale, or to turn a barren pasture into a meadow that will cut three tuns of hay to the acre. It will pay for him to raise fine horses and cattle, pigs and sheep. He ought to gratify his pride in the line of his calling, and not undertake to rival merchants and nabobs. If he fixes up his fields and breeds good points in his stock, people will not trouble themselves very much whether he says *cow* or *kow*, or attends spelling school late in life.

Hookertown, July 15th, 1862.

Yours to command,
TIMOTHY BUNKER, Esq.

[Squire Bunker's, like the rest of our correspondence, has to go through the mill.—ED.]

Book Farming.

We sometimes meet with farmers who deride book-learning as useless, yea, as even hurtful to the interests of agriculture. Give us experience, they say; that is enough, and that is safe. We know one farmer in particular, a shrewd, keen man, who learned his calling from his father before him, and who still learns much by visiting his brother agriculturists; but he has a mortal prejudice against book-farming. Probably, much of what he knows and prides himself on knowing, is really the product of scientific study by bookish men. If many of the useful methods which he practises had never been disseminated through books, perhaps neither he nor other farmers would ever have known them.

When a man has learned something really useful, (no matter how he learns it,) why should it not find its way into print for the benefit of others? But no—oh no! for then it would become book-farming. Some one has likened such a narrow-minded man to the great Omar, who said of the books in the Alexandrian Library, "If they contain only what is in the Koran, they are not needed. If they contain what is not in the Koran, it must be false. Let them be burned." So, if papers and books contain only what he knows, they are useless; if they contain anything he does not know, they must be false, and should be discarded, if not burned.

FIRST PRIZE SEEDLING—BROOKLYN SCARLET.

down the sides, was glowing with strawberries and roses, and crowded with gratified visitors from 1 o'clock on Friday till 6 o'clock on Saturday evening. Before visitors were admitted, the Committee, consisting of Dr. I. M. Ward of Newark; P. B. Mead, Editor of the "Horticulturist"; R. G. Pardee, author of the "Strawberry Manual," and Lowell Mason, jr., Esqs., had finished their examination, and very soon after, the names of exhibitors and the cards indicating the awards were placed upon the plates. The show was a very instructive one, on account of the great number of choice varieties, and the perfection of the berries. There was considerable competition for the prize offered for the largest three berries. The prize was taken by Mr. Heins of Woodstock, an amateur, with three berries of the Triomphe de Gand, 5¼, 5½, and 6 inches in circumference, and weighing altogether 2 ounces. The cut which we present represents them very well, and shows the tendency of the Triomphe to assume the cockscomb shape, so far as to form almost perfect rosettes, the stem being in or near the center of the flat, circular fruit. The show of varieties from the Marshalls was very fine, the berries being of large size, in fine order, and of valuable varieties. Mr. Heins showed other very well grown berries of choice kinds also, doing great credit to him as an amateur cultivator. Mr. Fuller has for some years been growing famous on account of his success in raising fine seedlings; the choicest of his collection were presented, with the exception of some which were already past, among which was the Bartlett, a fine berry, and very early; it is also one of those varieties, plants of which we have been distributing free to new subscribers. Mr. E. Williams' berries were fancifully arranged in cones, and made quite a show, attracting much attention from visitors, but the berries did not appear by any means so well as if they had been in plates, though the collection included many choice kinds. The collection of Mr. Prince was interesting from the number of his own seedlings that it contained. It was, however, entered for exhibition only, therefore shielded from criticism, and ought not perhaps to be compared with the beautifully grown berries exhibited by others.

HIGH COMMENDATION—GENERAL SCOTT.

The Agriculturist Strawberry Show.

The time appointed for the exhibition of Strawberries at the Office of the *American Agriculturist*, was well selected, taking into view the lateness of the season, as it came in the very hight of Strawberry time. A few valuable varieties were *past*, but most were in their prime.

We give a list of exhibitors and varieties shown by each on next page. The spacious office of the *Agriculturist*, with tables extending through the middle from Park-Row to Nassau-street, and

We give engravings of three of the seedlings, which received the notice of the Committee, and regret our inability to show also a cut of Mr. Burgess' *Little Monitor*, which received the premium as the best flavored seedling.

Brooklyn Scarlet, raised by Mr. A. S. Fuller, of Brooklyn, as announced in the list of premiums published last month, took the prize as the best seedling. It is well represented in the engraving. Berry large, long conical, symmetrical; color bright scarlet; flesh nearly white, firm, and juicy; seeds brown, prominent; calyx large; flower-stalk stout; flavor good; quality *best*. Plant hardy, vigorous, very productive, rather late; flowers perfect.

Garibaldi, raised by Mr. Wm. A. Burgess, of Glen Cove, received the second prize. Berry large, elongated, semi-cylindrical, (often more so than the cut represents); color rich crimson; flesh light colored, firm; seeds moderately depressed; surface glossy; flower-stalk erect and stout; flavor sweet and excellent; quality best; plant hardy, productive; foliage large, vigorous, and shadowing the fruit; early; flowers perfect.

General Scott, also raised by Wm. A. Burgess, received the high commendation of the Committee. Berry large, nearly round, with neck and calyx easily separable; color bright scarlet; flesh streaked with color, firm; seeds deeply imbedded; fruit-stalk erect, stout, flavor and quality best. Plant very vigorous, hardy; foliage large and of a dark, rich green; flowers perfect; ripens early.

SECOND PRIZE SEEDLING—GARIBALDI.

Little Monitor (Burgess) is a medium-sized, round, light-colored, white-fleshed berry of excellent flavor and exquisite quality, firm, but smooth and delicate in texture.

Monitor, another of Fuller's choice seedlings, was exhibited, but being the last pickings of the season, was not entered for the premium. We esteem it very highly as one of the very best of the larger berries. It is described by the committee of the Farmer's Club as follows: Berry very large, obtuse conical; color scarlet; flesh light colored, firm, and moderately juicy: seeds dark brown, prominent; calyx large, and easily parting from the berry; foliage large, coarsely serrated; flower-stalk stout; flavor good; quality best; very productive; early; flowers perfect.

[Mr. Fuller requests us to state that his 3 Seedlings, Brooklyn Scarlet, Col. Ellsworth and Monitor, are disposed of.]

The engravings we present were very carefully drawn from the fruit, and represent faithfully the size and character of the individual berries, of which they are portraits. The outline below the *General Scott*, is the size of a berry not of the group drawn, but not of an uncommon size. The berries selected for drawing the seedlings were not the largest in any case, but only a little above the average, and selected for showing the characteristic shape of each va-

WINNERS OF PRIZE FOR THREE LARGEST BERRIES—TRIOMPHE DE GAND.

riety. The outline with the large berries is that of the largest, from another point of view.

This exhibition, like others already held and purposed to be held in the office of the *American Agriculturist*, was undertaken solely with a view to advance the knowledge of an important subject, deserving the intelligent appreciation and investigation of the public; and except so far as it is an advantage to the *Agriculturist* to be recognized as earnest, wide-awake, and discriminating in all these matters, we sought no selfish ends. Our tables were offered free to any who would exhibit, and the decision of a wise and fair committee, very satisfactorily distributed the prizes offered where they were certainly due. It was therefore with no little surprise that we found notices appearing in one and another of our city cotemporaries, and in the Country Gentleman, reflecting both upon the management, and upon the exhibitors, stating that half the latter were not present in time for the examination, greatly extolling the berries of Prince & Co., and giving the impression that the fruit of those who came too late by far surpassed the others. Nothing could be more false, for not a single person who intended to show for a prize, failed to have his berries here promptly. We have traced these lying notices to their source; of their author—a man who would benefit himself by detracting from the fairly won laurels of others—we have nothing to say; but must express our surprise at the ungenerous notice, which our usually *gentlemanly* agricultural cotemporary gives "The Strawberry Exhibition in New-York."

LIST OF ENTRIES.

Prof. Huntsman, Flushing, L. I.—Seedling

John Rassbach, West Bloomfield, N. J.—Ward's Seedling.

Mrs. M. Pryer, Newtown, L. I. —Wilson's Albany.

Parsons & Co., Flushing, L. I.—Cutter Seedling, Triomphe de Gand.

Patrick Ryan, gardener to J. B. Colgate, Esq., 47 Wall-st., New-York.—Trollope, Triomphe de Gand, Austin.

H. E. Legg, Kingston, N. Y.—Wilson's Albany.

John Drummond, gardener to Mrs. J. H. Strong, Flushing, L. I.—Black Prince, Wilson's Albany, Jenny Lind, Triomphe de Gand, White (Bicton Pine), 3 large berries.

Wm. A. Burgess, Glen Cove, L. I.—Four new seedlings —No. 8 A, No. 8 B, (Garibaldi), No. 8 C, (Gen. Scott,) No. 8 D, (Little Monitor).

G. H. Banta, Tappantown, N. Y.—Wilson's Albany.

E. & G. Marshall, Poughkeepsie, N. Y.—Wilson's Albany, Great Austin, Triomphe de Gand, Longworth's Golden Seeded, Voorhies' Seedling, Scott's Seedling, Peabody, Ward's Favorite, Monroe Scarlet, Princess Frederick William, Gen. Havelock, Delices d'Automne, Jenny's Seedling, Trollope's Victoria, Pyramidal Chilian, Hovey, Wiley, Fragrant Scarlet, Westchester, Bicton Pine, Scarlet Magnate, Elton, Dundee, Huntsman's Pistillate, Duchesse, Feast's Fillmore, Imperial Scarlet, Duc de Brabant, Iowa, McAvoy's Extra Red, Hooker, La Belle Bordelaise, Black Prince, Brighton Pine, Walker's Seedling, Boston Pine, Madame Louese, Crimson Cone, Downer's Prolific, Prince's Climax, Large Early Scarlet, Ohio Mammoth, Bullett, Chorlton Prolific, Genesee, DeTiury, Jenny Lind, British Queen—(48 varieties.)

E. Williams, West Bloomfield, N. Y.—Triomphe de Gand, Ward's Favorite, Hovey, Wilson's Albany, Trollope's Victoria. (variety for name.) Great Austin, Scott's Seedling, Honneur de Belgique, Duc de Brabant, Iowa, Black Prince, Genesee, Ward's Favorite, Boston Pine, Moyamensing, Jenny Lind, Early Scarlet, Pennsylvania, New Richmond, Monroe Scarlet, Orange Prolific, Scarlet Cone, Crimson Cone—(25 varieties).

Wm. F. Heins, Woodstock, N. Y.—Hooker, Sir Harry, Triomphe de Gand, Great Austin, Victoria, Langstroth Improved, Wilson's Albany, Pyramidal Chilian, Cutter's Seedling, Longworth's Prolific, Scott's Seedling, Chorlton's Prolific, Jenny Lind, Boyden's Mammoth, McAvoy's Superior, Peabody, Ladies' Pine, Scarlet Runner, Bartlett, Early Scarlet, Downer's Prolific, Le Baron, Walker's Seedling, Prince Diadem, Athlete, Vicomptesse Hericart, White Pine Apple, Albion, Lennig's White, (new seedling, 2 seedlings for competition of flavor—(32 varieties).

C. S. Pell, N. Y. Orphan Asylum.—Wilson's Albany, Great Austin, Triomphe de Gand, White Alpine.

Wm. H. Goldsmith.—Hooker.

A. S. Fuller, Brooklyn, N. Y.—Seedling, Triomphe de Gand, Trollope's Victoria, Downer's Prolific, Deptford White, Duke de Malakoff, Monte St. Julien.

Solon Robinson, Yonkers, N. Y.—Wilson's Albany.

Wm. Kearns, gardener to Wm. Shaw, Clifton, Staten Island, N. Y.—Longworth's Prolific, Wilson's Albany.

John Boyce, Fishkill, N. Y.—Triomphe de Gand—(three large berries).

C. M. Saxton, N. Y.—Mead's Seedling—(exhibition.)

J. C. Thompson, Staten Island, N. Y.—Downer's Prolific, Great Austin, Triomphe de Gand.

J. Noble, Bowronville, Brooklyn, N. Y.—Four varieties.

W. R. Prince & Co., Flushing, L. I.—Ariadne, American May Queen, Great Austin, Chili Hybrid, Diadem, Bowner's Prolific, Fortunatus, Hooker, Hovey, Hudson's Bay, Fillmore, Globose Scarlet, Imperial Scarlet, Iphigenie, Jenny Lind, Ladies' Pine, Longworth's Prolific, Le Baron (Pine), Malvina, McAvoy's Superior, McAvoy's No. 1, Ophelia, Perfumed Cone, Primate, Prince's Late Globose, Scarlet Melting, Scarlet Prize, Scarlet Magnate, Sirius, Scarlet Globose, Barnard's Illinois, Stewart, Supreme, Victorine, Welcome, White Pine Apple, Seedlings (No. 1, 12, 13, 15, 18, 21, 22, 26, 28, 34, 38, 42, 45, 48), Bijou des Fraises Hautbois, Belle Bordelaise Hautbois, Male Hautbois, Green Pine Apple, Alpine Monthly White, La Mendonnaise Alpine, Montreuil Wood, English Ladies' Finger, Comptesse de Beaumont, La Sultane, Lucas, La Constante, Marguerite, Orb, Oscar, Prince Imperial, Rifleman (Ingram), Vicomptesse Hericart, Wizard of the North, Empress Eugenie, Triomphe de Gand—(57 varieties, besides the seedlings) (for exhibition.)

An Amateur.—Scott's Seedling.

George F. Meyer.—Hovey's Seedling.

L. M. Pease, N. Y. Farm School.—Triomphe de Gand, Wilson's Albany, (very superior).

D. P. Usher, Staten Island, N. Y.—Peabody.

Wm. Parry, Cinnaminson, N. J.—Triomphe de Gand.

F. P. Sanford, Orange, N. J.—Triomphe de Gand.

Mr. England, Bushwick, L. I.—Gooseberries.

Alfred Waller, Brooklyn, N. Y.—Whitesmith's Gooseberries.

A. S. Fuller, Brooklyn, N. Y.—Cherries for name.

Charles Mandeworth, Dutchess Co., N. Y.—Cucumbers.

A. Bridgeman, New-York.—Six pots Gloxinia, very beautiful.

What Blackberry shall we Cultivate?

None, say we, very decidedly, unless you have room for them, and will take care of them. We have plenty of wild fruit, in most years, of very fair quality, and unless we can get a steady supply of a superior article in our gardens, it were better to plant them with cabbage and sweet corn. These are certain to have room enough, and to be cultivated.

We are afraid many who have purchased plants, the last few years, under the inducements of pictures and advertisements, have made poor investments, not because we have any doubts of the excellence of the fruit, but of the good sense and skill of the purchasers. It will take years of experience and choked plants to get rid of the popular notion that, because a blackberry plant takes care of itself in the pasture, it will do the same in the garden, and yield good crops. It will do nothing of the sort. Neglect the best variety, and it will give not much better results than wild plants—a little fruit on one plant out of a dozen, in years of average moisture. We say then, unless you have a place in your garden that you can give up entirely to this plant, do not waste time and money in buying plants. They should be attached to trellises or wires, as this supports the lateral shoots much better than stakes. Most of the fruit grows on these laterals, and where they do well, they need support on account of the weight of the fruit. Trained in this way, it is easy to do the shortening-in at this season, with the thumb and finger, and to throw the energies of the plant into fruit-buds for next season.

The New-Rochelle very generally does well, and gives satisfaction to pains-taking cultivators. It is acid if picked before ripe enough to drop off, and it decays if neglected too long—the canes are sometimes winter-killed—charges that may be brought against other very good varieties of fruit. The fact that it has become so widely disseminated in so short a time, is a pretty good test of merit. It, however, fails in some soils and climates, with the best care.

American Forest Trees.

A little examination will serve to surprise one at the richness of our North American Sylva. We would by no means disparage trans-Atlantic good things; but when our own vast continent furnishes us so many species and varieties of trees, and some of them the grandest in the world, let us not overlook them in the search for foreign novelties.

It will surprise those who have not looked into this matter, to find that many rare trees, with strange-sounding names, are natives of our own land. Among conifers, take the following: *Pinus flexilis*, *P. ponderosa*, *P. monticola*, *P. Sabiniana*, *P. Lambertiana*, *P. insignis*, etc., are natives of Oregon and northern California. *Thuja gigantea* comes from the Rocky Mountains; *Juniperus occidentalis*, from Utah; *Abies Menziesii*, from Sitka, lat. 57°; *Cupressus Nootkaensis*, from the region about Nootka Sound; *Abies Douglasii*, *A. nobilis*, and *A. amabilis*, from Oregon, between lat. 43° and 50°; *Abies bracteata*, and *A. Williamsonii* lie a little further south than the foregoing. Near the sea, and in lat. 41°, we find *Cupressus Lawsoniana*, and *Sequoia sempervirens*, (California Red Wood,) and on the mountains of the same latitude the *Sequoia gigantea*, the famous Big Tree, called also *Wellingtonia* and *Washingtonia*.

These will serve as specimens taken from a single department; and there are many more, hardly less remarkable. Now, it gives one the sense of a new possession, and a feeling of patriotic pride, to find that such trees are American.

Another interesting discovery is, that some of these trees, though of northern origin—some of them even found along the snowy ridges of Oregon—are yet somewhat tender when transplanted into the same, or a lower, parallel of latitude at the East. Taking our illustrations again from among evergreens, here is *Thuja gigantea*, from the Rocky Mountains, in lat. 53°, but when set out in the neighborhood of this city, in lat. 40° or 41°, it is represented as "not quite hardy." *Abies Menziesii*, found at Sitka, lat. 57°, is cut up by the winters of lat. 43° at the East; *Abies Douglasii* grows wild on Vancouver's Island, lat. 50°, yet it can not be relied on here, in lat. 48°. Yet, again, strange to say, *Pinus ponderosa*, found in the interior of Oregon, north of lat. 50°, is as hardy all over our North-Eastern States as the native hemlock. The same may be said of *Thuiopsis borealis*, found wild north of lat. 50°. *Pinus Lambertiana*, found between 42° and 43° bids fair to succeed in the same latitude at the East. *Cupressus Lawsoniana*, found lower down, and near the Pacific coast, is trying hard to be hardy in the same latitude on the Atlantic.

Here we have a few instances, out of many, of a general fact, that the hardiness of a tree or plant can not be positively determined by the latitude or longitude in which it is found indigenous. Many circumstances go to determine its hardiness. It is affected much by its geological position, not a little, also, by its altitude above the level of the sea, by the prevalence of certain winds, by the amount of moisture in the atmosphere, by the protection of surrounding hills and forests, and other unknown and imperceptible causes. If, then, we wish to ascertain whether a certain, untried tree is hardy or not, we may form some *conjecture* from the latitude in which it is found, but can arrive at *certainty* only by a fair *experiment*.

This, too, should be borne in mind by every planter. In transporting a tree from one part of the country to another, he will be very likely to fail unless he surrounds the tree with nearly the same conditions of soil, exposure, etc., as it had in its original habitat. Take this familiar example: the *Kalmia latifolia*, and *Rhododendron maximum*, and American Holly, all grow wild north of 43° in New-England; but if we remove them south of that line into New-York, and yet give them unsuitable soil and aspect, they will dwindle away and perish. Unthinking persons will suppose they are "too tender for the climate," when in reality they are hardy enough, but are mismanaged.

In the foregoing paragraphs, we have only touched on a few points of interest in this subject, and must leave them for our readers to follow out at their leisure. At another time we shall return to the inviting theme.

A Hint to Tree Fanciers.

In our random experiments, last Spring, we met with a result which both surprised and gratified us. A Scotch larch, which had been planted in a certain spot, several years before, had become too large for the place it occupied, and must either be removed or cut down. What was to be done? A council was called, and soon a compromise was agreed on, for at least one year. The plan was to let it stand, but to head it in several feet at the top, and to shorten in the side branches full half their length. Heretical treatment, surely, but we gave it, and then waited results.

The tree being in a distant and secluded part of our grounds, we did not notice it particularly until about the first of June, when its appearance surprised us. The foliage had come out with unusual strength, and clothed the tree in a mass of heavy, rich verdure from top to bottom. We had trimmed it into a tapering or conical shape, like the Juniper, or Lombardy Poplar, and now it was a beautiful, thickly tufted shaft of the most vivid green, altogether unlike the tree as commonly seen. The leaves were fully double their usual size, being nearly as long as those of the Austrian pine, and of the same color, only glossier and brighter. Not an inch of trunk or limb could be seen amid the mass of leaves. At a little distance it resembled a fine specimen of the Austrian pine, pruned into the Juniper form. It is now one of the most remarkable sights in our grounds, and we congratulate ourselves on the discovery. *

Where to Feed Trees.

It is no uncommon thing to see a little circle dug around large fruit and ornamental trees, and a heap of manure applied. Perhaps this boys' play does no hurt, but what good does it do? We might fancy the old tree looking down upon the workman with a sort of disgust and indignation, and saying: "What are you about, Sir? Are you thinking to benefit me by scratching around my bole? No, no, Sir: my roots are out yonder, many feet away; my thousand mouths are far off, open and waiting for the food which they can not get so long as you confine it to my senseless trunk."

Any person can see a good illustration of our point, if he examines the grass under an oak or ash, or other gross-feeding tree. If the soil is rather poor, he will find the grass brown and dried in mid-summer; and the dryness will be greatest at the ends of the roots. This circle will enlarge every year, the roots exhausting the nutriment of the ground as they extend.

Now, obviously, the way to treat such trees, and all others that we wish to thrive, is to manure and till the ground all over the surface of their roots, but more especially at the extremities, for it is there that they take in the most of their food. This is the very best way, but the next best is to manure the entire surface of the grass above the roots once a year; the nutriment will much of it find its way down to the roots.

Potatoes Mixing in the Hill.

Some errors have more lives than a cat. Kill them thrice dead, and bury them, yet they will not stay dead. The above notion is one of these instances of persistent resurreetion. We shall not stop now to do anything more than hit the thing a rap, and then pass it by.

It would seem plain to every mind that no plant can "mix" through its branches and roots. Set the elm-tree in the same hole with a beech, and let their roots and branches grow and twine together for a century, and will there be any mixing of the two? Or let a red elm and a white elm grow side by side, or a red and white beech, and will either, in process of time, become streaked? Who has not seen the red and white peony growing side by side for many years without any mixing? And the same may be said of any plant which is propagated by divisions of the roots or tubers. Now, the potato is a tuber, like the peony. As we plant it, it is not the seed, but the tuber. And it will no more mix through this root than the peony through its. The only possible way of mixing this or any other plant is through the flower and seed.

When different varieties of a plant, (say the peony, potato, or what you will,) grow side by side, and blossom at the same time, the pollen of one flower is often blown, or carried by bees, to other flowers, and thus produces a cross fertilization. The stigma of one blossom is impregnated by the pollen of another blossom; then the seed is matured and ripens. Now plant this *seed* (not the *root*, remember, for that has not been affected at all,) plant the *seed*, and we shall be likely to get a new plant having a mixture of the two varieties. Thus, if we sow the seed-balls of our potatoes, we shall doubtless get a mixture of varieties, but we may plant pieces of their roots to all eternity, and there will be no mixture. Indeed these roots are not real roots, but only enlargements of the branches.

But some persons reply: we don't care a fig for science; for we have *facts* to prove that potatoes do mix in the hill. And here, a cotemporary well observes: "No theory, however absurd, can be started, but some are ready to furnish proof of its correctness from actual observation. Had the Messiah presented the question to the people of this day, which he did to the Jews some 1800 years ago,—'Do men gather grapes of thorns, or figs of thistles?'—some would be ready to reply in the affirmative, and declare that they had seen it done." So now, men have *facts* ready to prove that wheat changes to chess; the influence of the moon's rays on vegetation and pork; and that potatoes mix in the hill.

Let, however, a few other facts be noted, which throw some light on our subject. A parti-colored potato, if planted for a few years in a sandy soil, becomes lighter, and darker if grown in a heavy, clay soil. Plant only the light colored parts of the mercer, and the crop will be chiefly white. Plant several sorts of potatoes in the same field for several years in succession, and the finer varieties will be found mingled among the coarser, because the latter always

produce more abundantly than the former, and will get mixed with others, by careless hands. Sometimes a lot of one kind of potatoes is left in the ground over Winter, and next year we find them mixed with others—"mixed in the hill," indeed. Then, in the haste of gathering and housing, it is not strange that one sort gets mixed with another. And then in the Spring planting, when the different kinds are cut up and carried to the field, hired men will sometimes mix the kinds without knowing it. In fact, it is almost impossible to prevent this where small potatoes are used for planting, because the kinds are then not easily distinguished. *Facts* will always show that potatoes do not mix in the hill, unless it is done by the planter.

Celery in the Trenches.

It is much the best way to get a winter supply of this delicious salad, to make late plantings any time this month. Nothing is easier, after you learn how, than to grow it in perfection, tender, crisp, and juicy. The more rapid its growth the better. No plant delights more in moisture, and if the trenches are in well-drained soil, it is well to water copiously every other day. Stir the ground often, and do not begin to earth up much until the plants are a foot high or more. If the plants show any lack of vigor, top dress with compost from the sty or hennery.

Bare Spots in the Garden.

Sow them with spinage early this month, and you will have greens in September. If sown the latter part of the month, and covered with straw, prairie or sedge hay, a nice spinage bed is ready to be drawn from in May and June. Or the vacant places may be sown with quick growing flat turnips for late Fall use or for feeding. Even ruta bagas will grow to a good eating size if sown on rich soil the first of August. Radishes and lettuce may be sown at any time during the month for a late crop, and black onion seed may be sown late in August, or early in September, and left to grow thickly for seed for early rare-ripes in the Spring. Peas may still be sown, with a reasonable prospect of a crop before frost. Asparagus may be sown as soon as the seed is ripe, and one year will be gained in the future growth, as good strong roots will be ready to transplant one year from the following Fall or Spring.

Natural Products of Colorado Territory.

BY A COLORADO FARMER.

Grasses.—These are divided into lowland and upland: of the former there are two species—the jointed, coarse, tall, and the broad-leaved and soft. They are both cut for hay. The upland, are the bunch, and buffalo grass. Besides these we have wild oats, barley and rye in the valleys and on the mountains. I have seen the latter 6 feet high, with heads 12 inches long, at an altitude of 9,000 feet above the Missouri river. The oats, barley and rye are not worth cultivation.

Our highland grasses have a peculiarity unknown in the tame grasses. They ripen and cure on the ground, retaining a large part of their capacity to sustain and fatten stock. We can show you any day in Denver market, beef fatted on grass, and fed during the whole Winter on dry grass, equal to any grain and stall-fed cattle East, and doubtless more healthy. Fifty pounds kidney fat is not extraordinary here; this too from cattle worked across the plains the same year, and all our cattle are selected for work and not for beef. Poor stock of all kinds not only live through Winter, but absolutely fatten on our dry grasses.

Our cows show the superiority of these grasses in the quality of the milk. No better butter can be produced on the continent than here. I have a cow which has been milked all Summer, and all Winter, so far, without feeding hay or grain, and to-day she is fit for the knife. It may be added that she has had no shelter for two winters. At this date, January 8th, cattle teams are almost daily arriving in good order, having drawn loads 700 miles over the plains and subsisted on dry grass alone. If these statements are correct, you see how little feed is necessary for unworked stock.

The principal and best of these grasses is the Buffalo grass, so-called from the fondness of our wild cattle for it. I esteem it almost equal to oats in the sheaf. When it can be had stock leave all others and go miles to obtain it. It grows thriftily on the lower range of mountains and is greatly improved by proper soil and culture. In favored spots it produces a crop for the scythe. It is eminently adapted to our soil and climate; the roots retain their vitality in the dry sandy soil during all the fore part of the season, until the periodical showers come, when a seed stalk is thrown rapidly up, from 6 to 18 inches, bearing one to three small seed heads, standing at right angles to the stalk. There are no blades on the stalks, while the body of the grass is too short for any thing but sheep. This and other grasses are the principal reliance of our stock Summer and Winter. I think the Buffalo grass is, in many respects, superior to the famous blue grass; for winter feeding for sheep it has no equal, always furnishing food when the snow is off or not immoderately deep. It is certainly worth a trial, and if it grows well north and east, would be a valuable acquisition. I have demonstrated its capacity for improvement, and am well satisfied that it is eminently adapted to sandy and dry soils. Here it gets a little snow in Winter, and no rain in Summer, except about 4 weeks. I wish you could see the mutton fattened on this grass; you could form so much better an estimate.

Fruits.—*Raspberry.*—Mountains and valleys. Chiefly in the mountains, north-hill sides and burned districts. Berry red, juicy, good size, sometimes quite large, flavor excellent, prolific, continuing in bearing 5 or 6 weeks, 6 to 18 inches high, improved by culture,—excellent fruit, worthy of adoption. Will send you some berries if possible.* A superb wine is made from them. In the natural state they yield immensely.

Currants.—Black, Yellow and Red. The red is sweet—small—growing in the mountains, prolific, but of doubtful utility. Black and Yellow, large, thick skin, slightly astringent and very sour until fully ripe—about equal size, large berry, prolific, greatly improved by culture, and pleasant when fully ripe. I esteem the black best, and consider them superior to any of the cultivated varieties. But few are allowed to mature, as our people are crazy after fruits in the Summer. The specimens I send are from a stunted bush in dry ground.† The bushes frequently grow 6 to 8 feet high, and furnish fruit 5 to 6 weeks. A valuable acquisition. I may add here that all native products are hardy.

Cherry.—Commonly called Choke Cherry, but really a pleasant fruit when ripe; free from insects, size of large wild cherry, black, heart-shaped, bushes 10 inches to 10 feet high, prolific, and really more pleasant than the morello. Only valuable in the East as a curiosity.

Gooseberries.—Abundant, small, acid, black of no account. Our climate is admirably adapted to gooseberries. No mildew here.

Plums.—Some pretty good ones. Trees small, poor bearers, useless except here.

Thorn Apple—small, no account. *Hedge Thorn*—A splendid specimen of thorn bush, hardy, excellent for hedges.

Our fruits commence ripening in the lowlands first, and proceed gradually to ripen up into the mountains until cold weather stops the process. We have as yet none of the yellow cucumber bugs—the first season there were no small black turnip bugs, but last season they consumed every thing in their line.

We are sometimes troubled with grasshoppers too numerous to count; last season they could be gathered by the barrel. But these annoyances happen also in other countries. All we want is the general culture of staple products to reduce the price of living, and justify the application of labor to the working of the immense "placer diggings," to make this one of the richest mining countries in the world. We may yet attain this reputation with our present high prices for food, as new discoveries of leads and gulch diggings are made all the year through; this year promises better in every department of mining than any former year. At present all our gulch mining is done on separate claims, at great disadvantage. But we have organized one joint stock company which will demonstrate the practicability and economy of wholesale mining, and a new era in the product of gulches.

J. B. Wolle.

* Berries received, flavor good, but in the transportation, converted into "jam."

† The currants arrived in good order, and are as represented.

Sandwich Island Correspondence—II.

HAIKU SUGAR PLANTATION.

Makawao, *Honolulu Islands, 4th month*, 15th, 1862.

Increased attention is of late being given to the culture of the sugar-cane upon these Islands. The soil and climate are well adapted to its culture, and since the trouble in the sugar-producing regions of the United States has laid an embargo upon their products, new fields are sought, and it would not be surprising if some of these Islands should yet produce a large amount of sugar for export. In a recent visit to the Haiku Sugar Plantation, under the charge of G. Beckwith, from Massachusetts, I was shown over the place, and through the buildings for manufacturing the cane into sugar. The mill and boilers are new, of approved patterns, and capable of turning out about 4,800 pounds of sugar daily. The refuse cane, or bagasse, passes from the mill to the furnace, and forms nearly three-fourths of the fuel used. The plantation embraces about 7,000 acres, only 700 acres of which are now in cane. Nearly all of the work on the plantation and in the mill is performed by natives, under the charge of overseers. The laborers receive $6 to $8 per month, including their board. The sugar is put into half barrels or kegs, holding about 112 pounds each. The kegs themselves, or the prepared materials from which they are set up, are manufactured in New-England, and shipped here in bundles or shocks. The mill is near the shore, upon the bay of Mariko, where small vessels take the sugar on board for Honolulu, to be subsequently shipped to California and Oregon.

Besides the Haiku plantation, there are three others on the island of East Maui, whilst many cultivators raise small patches of one-half acre to three or four acres of cane, and take it to the plantation mills for manufacture. The yield is from one to three tuns of sugar per acre, the wholesale price of which is 6c. to 8c. per pound. Joel Bean.

The Raspberry.

The season of bearing, now nearly or quite over, is a time when the canes are apt to be left to take care of themselves. It is not easy to realize that the grass and weeds that are allowed to spring up between the rows will injure the crop for next year. These should be kept down by frequent hoeing or raking, and if the canes are not vigorous, manure should be applied, either as a surface dressing or in the liquid form. The plants, however, should not be stimulated later than the first of September, as it is highly important that growth should cease and that the wood may be well ripened, whether the canes remain above ground, or are slightly covered.

The finest varieties of this fruit in general cultivation are the red and white Antwerp, Fastolf, Orange, Cushing, French and Franconia. These are good enough in some localities, especially in the valley of the Hudson, and if they did as well every where as in favored localities, nothing more perhaps could be desired. But the raspberry is not so easily suited with soil and climate as the strawberry and blackberry. Very little has been done to improve this fruit, until quite recently, and for eight of the thirty four varieties in Downing's list we are indebted to Dr. Brinckle of Philadelphia. It is altogether probable that new varieties are yet to be originated, better adapted to their native localities than any thing we now have. This is a very promising field for amateurs.

The production of new varieties is not difficult. The birds are helping in this work, and it is not infrequent that new seedlings are found in gardens that can be traced to no other origin. If these chance plants that spring up by the fence, or in secluded spots in the garden, were oftener saved, we should have a much larger list. We are indebted to a chance seedling for the best berry upon our own premises.

The raspberry delights in a moist vegetable loam, deep and rich. Its native locality is upon hills and mountains, growing abundantly in ravines where there are large collections of leaves. Wherever the forest is cleared up, the raspberry soon makes its appearance and often covers the land. The whole Green Mountain region is so abundantly stocked with this fruit, and the wild fruit is so fine, that it is undoubtedly a hinderance to their cultivation in gardens. That is the best variety for you which will do best in your garden, whatever the books may say. As a special manure for this plant nothing can be better than the soap-suds made in the family. For methods of training, laying down, etc., see June number.

Cherries.

We are in no danger of over-estimating this delicious summer fruit, coming as it does in the heat of Summer, tempting us with an infinite variety, both in form, size, and flavor, hardy beyond any other kind of stone fruits, and adapted equally for the dessert and culinary purposes. We seldom give consideration enough to the value of the cherry as an ornamental tree, and in a selection of varieties this is most important, at least so far as to enable us to place the ornamental varieties where they will most adorn our grounds and gratify good taste. The Black Tartarian, one of the finest of the black hearts, is pre-eminent for the beauty of its foliage and habit. In the classification of cherries there is considerable difficulty, the various groups run so imperceptibly into one another. At first it was easy to see four groups: Hearts, Bigarreaus, Dukes, and Morellos. We now see in the newer varieties the hard-fleshed Bigarreaus gradually shading off to half-tender and

Black Tartarian.

Elton.

tender-fleshed Hearts, and those otherwise of the Heart character possessing peculiarities of the Bigarreaus. So, too, the sweet Dukes and sour Morellos—very similar in the rounded habit of the trees, and in bearing fruit on both the old and new wood—blend by almost imperceptible approximations, but the character of sweetness or sourness remains as a convenient distinction. These groups, Dukes and Morellos, are by far the hardiest of the species, flourishing both at the north and south where the others fail.

Early Purple Guigne.

We may take the *Black Tartarian* as a sample of the Heart cherries. We give a cut of it with the more pleasure, because it stands so high in public favor, and is so worthy of cultivation for its many excellences. We have specified the beauty of the tree. The fruit is very large, with an angular or uneven surface, the skin of a brilliant black, or purplish black color, the flesh purple, half tender, and very juicy, bearing transportation perfectly; the flavor rich and sprightly. It ripens among the earliest black cherries.

The *Elton* fairly represents the Bigarreaus, and is an exceedingly fine fruit, ripening nearly as early as the preceding. The fruit is large, yellow in the shade, but beautifully mottled with colors on the side exposed to the light; of a pointed heart-shape; flesh yellowish, firm, but when fully ripe, tender and juicy, with a sweet and very rich and agreeable flavor. The tree is a vigorous grower, somewhat drooping in habit.

The *Early Purple Guigne*, (pronounced geen), is the earliest of cherries, ripening in this latitude about the first of June in some localities. The tree has little beauty, but by pruning while young, may be made to take a pretty good shape. The fruit is early and excellent, heart-shaped, color dark purple when ripe, flesh dark, juicy, sweet, and well flavored. The stem is very long, and inserted in a narrow basin. This is found to be a favorite variety at the West.

The *Belle de Choisy* is a very delicious cherry, and a pretty fair example of the Dukes, the tree having the low, round-topped habit of this group, and the fruit the round and slightly depressed form. Skin thin, yellow, and mottled with pink, or red, on the exposed side. Flesh amber-colored, stained with pink; sweet subacid, rich. It ripens about the first of July.

Morellos.—As a type of the Morellos, or pie cherries, we give the Early Richmond. The tree is round-topped and spreading, and very productive; the fruit of medium size, round, borne in pairs, the calyx usually adhering around the short stem. Skin red, becoming dark-brown if it hangs long. Flesh reddish, juicy, very sour, but of an agreeable flavor. The fruit remains on the tree ripe during the entire month of June, and even later. It is an invaluable fruit in every garden for culinary uses.

We have here given a few of the most desirable sorts of cherries of quite distinct characteristics—there are others which should be added to a list of trees to plant. One of the great charms of the fruit is the variety which we may easily possess. In addition to those already

Belle de Choisy.

Early Richmond.

named, we add: Belle d'Orleans, Gov. Wood, Coe's Transparent, Bigarreau, and Great Bigarreau, Black Eagle, Downer's Late, and Carnation.

The Currant.

This is the fruit of all others for dog-days. Most people have a very strong craving for its acid, and this, perhaps, is a good indication that it meets some want in the system. "Souring the crop" is the very expressive term by which the farmer boys indicate a feast of this fruit. It should be provided by every one who has room to grow the bushes. It is more hardy than almost any other of our fruit-bearing shrubs, bears fair crops without much coaxing, and is, with generous treatment, loaded every year.

There are some twenty five varieties in cultivation, each good for some particular qualities. But most of them are little if any better than the old red and white Dutch so widely known, so that he who has these may well be content. La Versailles has large, long bunches, and is among the best of the new varieties. The Cherry currant is distinguished for its size, and its acidity. It is not so generally known as it should be, that this shrub rejoices in a rich clay loam. Where it does not flourish, clay would make a good amendment to the soil. The fruit

can be increased in size and quality, by training upon wires or as a tree, but it does so well in its natural bushy form, that few will be at the pains to change it. Currants are frequently grown by the acre for market, and the results compare favorably with those of the other small fruits.

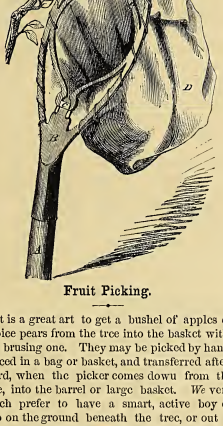
Strawberry Farming.

It is only within a few years that the cultivation of the small fruits on a large scale for market has been much pursued in this country. Now, however, strawberries, currants, blackberries, raspberries and cranberries, are cultivated in plots of many acres in extent, and ordinarily realizing to their owners great profits compared with the investment in land, labor, etc. At the recent strawberry show at the office of the *American Agriculturist*, among the berries showing the best cultivation, were some splendid Triomphe's and Wilson's, from Rev. L. M. Pease, of the New-York Farm School, near Mt. Vernon, Westchester Co. This farm we visited, and it has many points of interest besides the strawberries.

Mr. Pease is widely known for his beneficent and successful exertions in behalf of poor children of this City, he having given the character to the Five Points Mission, and House of Industry, which he may almost be said to have founded. Seeing the need of giving poor children a means of *earning* a respectable livelihood, he some years since purchased this farm and turned it over to the "House of Industry," when that body was incorporated, by which institution it is now leased to a Board of seven Managers of the most prominent benevolent citizens of New-York, of whom Mr. Pease is one. The Farm has been cleared of rocks, bushes, fences and water—the rocks buried and made into drains, the bushes and fences, except the stone walls, burned, the water gathered into pools at different levels to serve as reservoirs for irrigation. This he is preparing to conduct on an extensive scale, and now uses the water with marked advantage in some extensive strawberry beds. On this farm, in connection with other ordinary farm crops—corn, potatoes, rye, oats and grass—there are some five acres of strawberries in bearing and several more which will come into bearing next year. The varieties are chiefly Wilson's Albany and Triomphe de Gand. We estimated the yield at about 300 bushels to the acre, and Mr. Pease thinks that certain parts will yield at the rate of 400 bushels of Wilson's Albany.

The culture of these strawberries, except the preliminary preparation of the ground which is very thorough, is done entirely by boys from 12 to 15 years old, and we have never seen strawberry beds cleaner or more flourishing, and we may add, we never saw such a profusion of fruit of a uniform, large, or above medium size. On a single plant 2 years old, taken at random, we counted more than 200 berries, green and ripe. In general, they are planted 14 inches apart with 18 inches space between the rows. Grass and other farm crops showed excellent culture and looked finely. Mr. Pease uses an abundance of manure both from the stall and compost heap, and besides purchases fertilizers. He says he can not afford to farm without plenty of manure, and if he can not make all he wants he must buy it.

The boys are encouraged to diligence by certain privileges and payments depending upon their steadiness and efforts. They each have garden patches to cultivate of their own, according to their own tastes. One is trying for the big squash or pumpkin premium at our proposed pumpkin show. Others have constructed unaided a small "green-house," where we found a moist atmosphere and the conditions of rapid growth; but it is too small and will be too much exposed to bear the winter. It would have been better on the south side of a big rock or half buried up in the ground. Happier, pleasanter boys we never saw. They are in a fair way to make good farmers and gardeners. Snatched from surroundings which are the most debasing in this hot-bed of iniquity, (New-York City,) they are saved to themselves and to society. The number on the farm will be increased as fast as work can be provided. A fine new barn has been built, and other buildings are in contemplation.



Fruit Picking.

It is a great art to get a bushel of apples or choice pears from the tree into the basket without bruising one. They may be picked by hand, placed in a bag or basket, and transferred afterward, when the picker comes down from the tree, into the barrel or large basket. *We* very much prefer to have a smart, active boy or two on the ground beneath the tree, or out a little on one side, to catch the fruit as fast as we pick it. This gives the picker both hands, and ability to draw in limbs and pick without jarring, and to take ripe or partially ripe fruit at pleasure. The fruit sustains no injury, if caught, and as it is placed in the basket or barrel, one or two at a time, this is all the handling required. It has no fall, even from a very small hight, and is absolutely unbruised.

Fruit Pickers, however, are of use, and a good one is of great value. There are trees we can not climb into, and others, the limbs of which can not be brought within reach, so it becomes necessary or desirable, to have a means of picking attached to a long pole. One of the best of these contrivances, whose name is *legion*, is the one illustrated above. It is Goodwin's patent, and consists of a light, cast-iron frame, *B*, (bad if it were to drop and hit a stoue,) upon one side of which a bag, to hold the fruit when picked, is attached. An interior part of the frame contracts the opening at either end, and conducts the stem of the apple or pear against a knife-blade *c*, which is intended to cut the stem; if the turning of the picker does not cause the fruit to drop. This will ordinarily occur; and it will be noticed, that a very good leverage to pick the fruit is obtained. The cost of the implement, we believe, is 50 cents.

Packing Fruit for Transportation.

Persons often wish to send packages of nice fruit to distant friends, yet fear it will not reach its destination without being badly bruised in the transit. There need be little fear of this, now that modes of packing are so nearly perfect, and express companies carry and deliver parcels with such care and dispatch. Among the ways of packing, here is one: Prepare a box of suitable size, and provide a quantity of cotton wadding, and several sheets of tissue-paper. Put two layers of cotton on the bottom of the box. Wrap each specimen—be it peach, pear, plum, grape-cluster, or other fruit—in tissue-paper, and lay it on the cotton. If trouble is taken to tuck a bit of cotton between each specimen, it will be all the better. Over the first layer of fruit, place a sheet of wadding, and proceed as before until the box is full: then finish off with a layer of cotton moderately pressed down, to keep the fruit from shaking about. Nail on the cover firmly, and dispatch box to place of destination. The aroma, and even the very bloom of the fruit, will be mostly preserved. Some persons use sweet bran, in place of the cotton, and with excellent success.

What to do with Summer Fruit.

Much Summer fruit is very transient, decaying even before it falls from the tree, and sometimes even before it is ripe. This is true of many pears. Picked, or shaken from the tree and picked over, they make excellent *perry*, which is like cider, but more delicate and winelike. It needs a cool cellar to undergo its fermentation in. Apples should be made into cider. Sweet, it brings a high price in market, and is a delightful cooling beverage, but does not make so good cider as later, when fermentation is less rapid. The small hand mills and presses are very good for pressing fruits, and a family may supply itself with the juices for preservation, and considerable quantities for sale.

Cockroaches and Croton-bugs.

An Entomological correspondent of the *Agriculturist* to whom we asked some questions about these creatures, writes: "It is a comfort to us in considering these nuisances to think that neither of them originated in this country—the cockroach (*Blatta orientalis*) being a native of India, and thence carried all over the world by the aid of commerce, and the croton-bug (*Blatta* (Ectobius) *germanica*), originating in Europe. The croton-bug seems to thrive better in this country than at home, for in our large cities it is found in millions, really taking the place of the prevalent cockroach in many localities. European writers, as far as I have seen, speak of it as not very abundant. We have several indigenous species of Blatta, but, like the aboriginals, they seem to choose the freedom of the woods and fields.

"The cockroach is larger than the croton-bug, the former varying from 8 to 14 lines, and the latter 5 to 10 lines in length. The first is of a rusty brown color—the head with a white dot on each side between the eyes—the wing covers abbre-

viated and truncated at the end in the male, and only rudimentary in the female. The second is a livid yellow color, very glossy, with black antennæ and eyes, and two parallel longitudinal black lines on the shoulders. It seems to take to water pipes rather more naturally than the former. Otherwise their habits are very much alike, both species being fleet-footed, restless and sneaking—having insatiable appetites—not being at all particular as to their diet, 'lovers of darkness rather than light,' fond of grand pow-wows on kitchen floors, and breeding by the hundred thousand. True Ishmaelites, 'their hand is against every man.'

"In New-Orleans I have found domesticated another (tropical) species, which does not yet seem to have a strong foothold in New-York, the *Blatta gigantea*, which is of a livid color, with a large quadrate blackish spot on the thorax. This grows to be over two inches in length, and is the kind about which mariners are wont to discourse. In this climate we have very little idea of the way in which they increase and swarm in the tropics, both on sea and land. On the land nature has provided many destroyers which keep down the surplus stock, such as ants, spiders, and many of the smaller animals. On shipboard, it becomes necessary now and then for every person to come upon the deck, or to go on shore, and to make an intense smoke between decks and in the hold, which kills every living thing within its reach." N.

However interesting the facts about the vermin, as regards their origin, etc., are, there is another class of facts which interests us still more, namely, how to get rid of them. We must, however, beg our readers to bear in mind that where filth, decaying matter, and such like things exist, it is far better that it should be converted into living organisms than remain to foul the earth and air, and pollute the dwellings of men; so by a providential ordering of things, there are insect scavengers provided, which multiply in proportion to the abundance of food they have, and which render innoxious vast quantities of matter which otherwise would be productive of disease and death incalculable. We may regard them then as good friends, though sometimes disagreeably familiar, and uncomfortably numerous. A house infested with roaches or croton-bugs, may be effectually cleared of them by exposing it throughout to a freezing temperature, which is easily done in houses standing isolated, the family leaving it for a few days in cold winter weather, allowing the fires to go out, and giving free ventilation. This is impracticable in cities, and often in the country, where this nuisance is spreading quite rapidly, brought in flour barrels, and provision cases of various sorts. Probably the next best remedy is what is known among housewives as "dry *green paint*," to painters as "*Paris green*." This is arsenite of copper, an exceedingly poisonous substance, of a bright green color. The color is a great safeguard against its accidentally contaminating any thing eatable—which is the great danger with white arsenic, and the poison is so subtile that it affects the insects without their eating it, when dusted about in their runs, in cracks of the wainscoting and floors, around water-pipes, etc. This poison should be used in no larger quantities than absolutely necessary, for when considerable quantities are about the house, especially if it is near warm flues, or hot water pipes, it might affect the atmosphere so as to be injurious. The air of rooms painted or green-washed with it, or covered with paper on which this was the coloring matter, has, in repeated instances, proved highly poisonous and even fatal. There is also an article very generally for sale over the country, as a rat-poison, the basis of which is phosphorus, rendered sweet and palatable, which these insects will eat, and which is certain death; but we place most reliance on the green paint, for this is lasting. It destroys also other insects.

Chloride of Lime.

It is not generally known that the smell of chloride of lime is particularly offensive to many kinds of animals, especially to the common fly, the gadfly, and stinging flies of all descriptions, so obnoxious in stables. A sure means to get rid of these troublesome visitors is to place a vessel filled with chloride of lime upon a shelf, or a board suspended to the ceiling. This being done in the evening, and a window left partly open as an outlet for the flies, none, or very few, will be found in the room in the morning. The smell of chloride is by no means injurious to man or beast; on the contrary it is wholesome as an absorbent of deleterious miasms pervading the air. It need hardly be recommended to repeat the expedient at short intervals, say at least once a week, the more so as it will cost but a trifle and will give no trouble.

In a room—kitchen, pantry or cellar—where chloride of lime is kept, mice and rats will keep off, as indeed they will from any place where the article is used. We have seen the experiment tried very successfully in a large Inn at Nuremberg, long infested with rats and mice, all of which disappeared almost suddenly, not only from the house and outer buildings, but also from the stables and yard.

The use of chloride of lime is not less efficacious for preserving plants from ants, caterpillars and other insects. We have a cabbage field cleared of this nuisance by the simple process of sprinkling the plants with a solution of chloride and water; which may be done by using a common hand broom or a paint brush. To our certain knowledge, a piece of ground sown with white cabbage was thus thoroughly preserved from insects, while in the neighboring pieces the plants were actually destroyed by them.

The same remedy is also applicable to fruit trees which may be preserved or purged from caterpillars, etc., by mixing a pound of chloride of lime with half a pound of lard; this will form a kind of paste, which should be wrapped in tar, and tied to the stem or to the thicker branches of the tree. All insects will drop off almost instantaneously, nor will any be tempted to crawl up again. Even sparrows will keep away if the leaves have been sprinkled as aforesaid.

Experiments are being made as to the efficacy of chloride of lime compared with sulphur as a remedy for the vine disease, and the destruction of the *aphis* or vine-fretter.—*Deutscher Telegraph.*

Material for Pickles.

There is a prejudice against pickles, perhaps it is because boarding-school girls of a sickly hue, are said to dispose of marvellous quantities of them. Whatever the prejudice, it is not well founded. It is a blessed discovery that salt and vinegar will carry over something of the greenness of Summer into the barren Winter. Almost any vegetable preserved in good cider vinegar, (not dilute sulphuric acid,) is a healthful condiment, and aids digestion. There is nothing better than the cucumber, and the vines are full of these now. Pick them while small, and preserve in strong brine. Cabbage makes a good pickle, but we can keep this fresh through the winter, and use raw, which is better. Peppers, the thick-skinned squash variety, are almost indispensable in the pickle jar. We would suggest onions, were not the prejudice against and the love for this Egyptian esculent universal. Then come mangoes, prepared from green fleshed melons, well stuffed with cabbage, horse-radish, nasturtiums, white mustard and spices. This suits us a shade better than cucumbers. Beans in the pod, peaches not quite ripe, butternuts and hickory nuts, in the very green state—and last, but not least, tomatoes make good pickles. This list is extended by other recipes in this number; but these will enable the thrifty housewife to fill the pickle barrel.

String Beans and Green Corn in Brine.

It is not generally known that string beans can be kept in salt, the same as cucumbers. When of suitable size for cooking, pick and string them, and break in small pieces, as for ordinary boiling, and pack in firkins or stone jars, using a layer of salt, two inches in depth of beans, more salt, and so on until the vessel is filled, covering with a good coating of salt. Over this place a board cover, kept down by a stone or other weight. The salt soon extracts sufficient water from the beans to cover the whole with brine, in which condition they will keep for a year, if required. To prepare them for cooking, soak in water over night, and if too salt freshen in more water before boiling. Green corn ears may also be preserved in salt, and when required for use, soak till freshened, and boil.

Cucumbers, for pickles, may be put in with the beans, thus saving an extra firkin; as they are pickled in precisely the same manner, freshening in water, and putting in vinegar, with or without spices before using.

Various Recipes.

Tomato Catsup.—Select well-ripened, smooth tomatoes, boil with a very little water until tender, remove the skin, and rub the contents through a fine wire seive to separate the seeds. To each bushel of the fruit add 3 quarts cider vinegar, 2 lbs. salt, ¼ lb. black and 2 oz. Cayenne pepper, 3 grated nutmegs, ¼ lb. allspice, 6 finely chopped onions, and 3 lbs. brown sugar; boil the whole for 1 hour, stirring it frequently, and strain again through the wire seive. When cold, bottle and set away in a cool place. It is ready for immediate use, or it may be kept a year.

Sweet Pickled Quinces.—The most common use of quinces is as sweet preserves. They also answer a good purpose when sliced up and mixed in small quantities with apple-sauce, giving the whole a pleasant, aromatic flavor. They make a good pickle, also. Boil in vinegar with sugar, and add cloves, cinnamon, etc., to suit the taste. The best way is to pare and quarter them and cut out the cores. Boil 10 pounds of fruit, adding 5 pounds of sugar, and about 4 pints vinegar, one ounce of stick cinnamon, and ½ ounce of cloves. When well boiled, put in a jar and pour over the syrup.

Baked Quinces.—This fruit may be baked like apples, adding syrup, or sugar and water, while baking. Certainly every one who likes a sour baked apple, will relish a baked quince. They are very good simply baked, and eaten with powdered sugar.

To Dry Sweet Apples.—Bake as for the table, then dry in a brick oven. They may be soaked, heated, water dried away, and restored very nearly to the condition of a fresh baked apple. Stewed in more syrup, they make a much richer sauce than the common dried apples.

Peach Jelly.—Pare well-ripened peaches and remove the pits; boil the fruit until quite soft in water enough to cover it; strain through a coarse bag and add 1 lb. white sugar to each quart of the liquid, boiling down until upon trial it stiffens when cooled. If it does not stiffen sufficiently, add a little isinglass. Put in jelly glasses, tumblers or bowls, and paste white paper over them. After setting a short time in the sun, preserve in a cool, dark place.

Blackberry Jam.—Blackberries, in almost any form, and wine made from them, are very pleasant and wholesome, and besides are conceded to be good medicine for the "Summer complaint," and housewives and nurses look out for a good stock of blackberry jam. It is easily made, and there is no difficulty in keeping it. To each pound

of ripe fruit, stewed in a porcelain kettle for five minutes, add 1 lb. light brown sugar, and mash the contents fine with a strong iron or wooden spoon while still upon the fire. When well mixed and boiled 15 minutes longer, stirring it well in the mean time, fill the jars or glasses, and set away.

For the American Agriculturist.

The Farmer's Lot.

What joy the farmer finds!
He views green acres around him lie
Broadly beneath the open sky,
And not a fetter binds
His free and stalwart frame.

No blush or tinge of shame
E'er rested on that cheek of thine,
Or any angry flush of wine,
That sets the blood on flame,
Strong reaper of the grain!

Thy limbs are free from pain,
And thine are sinews stout as steel,
Which, while they keenly feel,
All their young strength retain,
Because thou art a man,

Created on God's plan;
And, like a denizen of air
Living, that chainless joy to share,
Which in those days began,
When Adam trod the ground,—

That sacred soil he found,
So beautiful from God's own hand,
That lovely, green, unwounded land,—
By full fruition crowned.
Blest is the farmer's toil!

He cultivates the soil,
And lives contented with his lot,
Cast in one dear, delightful spot,
Far from the world's turmoil—
And him no avarice binds.

Such joy the farmer finds;
And he will find it to the last,
Till life and all its cares be past,
Its healthful labor done,
And rest immortal won.

Fort Washington, July 7, 1862. PARK BENJAMIN.

The Editor with his Young Readers.

A LETTER FROM MR. JUDD, NOW IN ENGLAND.

LONDON, England, July 1862.

DEAR YOUNG READERS:—When I left home the last of May, I did not intend to write anything for the *Agriculturist*. All my friends thought that I had worked steadily so long that I *must* lay down the pen and rest my brain a little while. I also wanted to devote sometime entirely to gathering information that might be useful in furnishing matter for the paper hereafter. But it seems so long since I addressed you that I shall venture to break over the "rules" and have a little chat with you.....I have seen so much to talk about that I know not where to begin.—Perhaps a few items, gathered here and there, may interest you.—The passage across the Atlantic, in the Great Eastern, was very pleasant. The great ship was itself a constant wonder. In length it will more than reach across a square field of 10 acres. We very frequently took a walk of over a mile by going only four times around the deck. The ship is so wide that three barns or houses each 40 feet long can be set end to end across its middle. With our SMALL load of about 1000 persons, 3000 *tuns* of wheat, 2000 *tuns* of butter, cheese, etc., and 4000 *tuns* of coal, the vessel sunk into the water about 26 feet, leaving 28 feet of her hight still above the water. She would float with the weight of more than 250,000 men on board. Yet, great as is this vessel, with all the weight of the iron of which she is built, of her mammoth engines and other apparatus, she moved along through the water at the rate of 350 to 400 miles a day, (almost as fast as a railway car), and yet as easily and gracefully as a swimming duck or swan. The paddle wheels on the sides, and the screw propeller underneath, never stopped an instant in 9½ days, from Sandy Hook bar New-York, to "Bell Buoy," off Liverpool. When the wind blew hardest against the sails, we could scarcely feel any motion. When there was little wind, the great ocean waves coming *across* our path would gently roll the ship from side to side. Standing on the side then was like being on the end of a see-saw plank, a-going gently up and down once in 10 to 12 seconds. We did not enjoy . e supposed good medicinal effects of sea-sickness....The first three days nothing but water and fog could be seen. Then we crossed the south point of the "Newfoundland Banks." These do not come very near the surface, so that vessels go right on them. At one place we saw nearly 50 vessels catching codfish with long lines let down to the deep banks.—The first day we went directly east from New-York or Sandy Hook; the second and third a little north of east, and the next a little more northward, to latitude 45°, and longitude 45°, after which we steered straight to the south point of Ireland (Cape Clear), which was the first land seen in 8½ days. It took another day to go up the Irish Sea or Channel, between Ireland and the West Coast of Wales and North England. It may interest you to take down your maps and trace out a ship's course across the ocean. Most steamships go a little further north, crossing over the northern part of the great Newfoundland Banks, and passing near Cape Race. We kept a little further south, because in early Summer icebergs, that is, great mountains of ice, come floating down from the North, and ships sometimes strike against these in a thick fog. This is about the only danger in crossing the Atlantic in a good ship during Summer. You will see that when in latitude and longitude 45°, we were only 15 degrees south of Greenland. Even in June the winds came down from the north as cold as a January blast in New-York. We had to put on two sets of flannel, as well as overcoats and shawls to keep warm when walking on deck. During the passage we had meetings, singing concerts, discussions, mock trials, etc., and the time passed rapidly and pleasantly away. There was something very grand in looking out upon the ocean, that seemed to meet the sky all around; and to reflect that the expanse of water was so great that, though moving over nearly 400 miles of it daily, no land was in sight for more than a whole week. What must be the great Pacific ocean! Nearly a thousand ships ply between New-York and Great Britain, yet there was so much room that we saw only five or six of them in our whole trip! As we went up the Mersey River to Liverpool, there was a fine spectacle. Thousands of people came out in steamboats, with flags flying and bands playing, to welcome the Leviathan ship, while for many miles both banks of the river were crowded with tens of thousands of people waving their hats and handkerchiefs, and cheering as we passed. The ships in the river "manned their yards," that is, all the sailors climbed up the ropes, and on to the masts and yards, or cross beams—looking at a little distance like flocks of huge birds in the rigging. Such was our welcome to the Old World.

LIVERPOOL is a pretty large city, containing nearly 400,000 inhabitants. It is 206 miles, by railroad, northwest from London. It is a great seaport, receiving and sending out more than $300,000,000 worth of merchandise every year. It is more closely connected with America than any other city of Europe, over one-third of all its trade being with New-York City. The "Docks" of Liverpool are noted. The tide rises and falls 20 to 30 feet in the river. The chief docks resemble Canal Locks; that is, they are great stone basins or channels, into which ships are floated at high water, and then the gates are shut so that when the tide falls the ships remain floating in the water retained by the gates. At a little distance, the long rows of ships look as if bedded in the soil. When unloaded, and loaded again, the gates are opened at high water, and the vessels are floated out into the river. When they wish to examine or repair the bottom of a vessel, they have only to let the water off through trap doors, as the tide falls, and the vessel is left high and dry. The gates and traps being then closed, the water does not flow in at the next rise of the tide. I shall not have room to tell you more about this city, and can give only a few notes about other cities. I went southwest from Liverpool about 100 miles, to Holyhead, passing through the north part of Wales, and on cars through the great Brittania Tubular Bridge. This Bridge is an iron tube 1513 feet long, over the Menai Straits, from Wales to the Island of Anglesey. It is made of wrought iron plates riveted together, and is so strong that a long train of cars passes rapidly through it, 100 feet above the water. Wales is a hilly country; we passed right under several high hills through tunnels, some of them a few rods and some nearly a mile long. The houses are mostly stone, and few of them are more than one story high. I could hardly understand the people at the railway stations, though they talk the English language. They pronounce words differently from us. The fields are all divided by hedges and ditches, with an occasional stone wall. I never before saw so many crows as abounded all along this route. (*Mem.* All through Great Britain, route is pronounced *root*. They never say *railroad* depot, but railway station. They say coaches or carriages, and not cars. The cars, or coaches, are divided into rooms, with two seats for three persons each, facing each other, so that half must ride backward. A "guard" in uniform, not called a conductor, rides in a forward office or car. Your tickets are shown as you enter a car, you are then locked in, and near the end of the journey the train stops and a station agent comes along, unlocks the car, takes your ticket, and the train runs into the station. There are 1st, 2nd, and 3d class coaches, the 3d class having no cushions, and but poor ones, if any, in the 2nd class. The 3d class fare is about 2 cents a mile; the 2d class 3 to 4 cents, and the 1st class 4c. to 6c. a mile. They have but few 1st class coaches, and these are mainly designed for "Lords" and "Nobles." Americans being all nobleman, and accustomed to good cars at home, generally get in among the "Lords" and "Ladies" of this country.)

Passing by water 60 miles from Holyhead in Anglesey, over to Dublin, Ireland, I spent some time in driving all round the city, but can not stop to describe it. It appears more like New-York than any other town I have seen, except Liverpool, perhaps, though the buildings are mostly built of stone, and the streets narrower, and more broken up and crooked than in New-York.

A ride of about 60 miles through the country from Dublin to Belfast, on the Northeast coast of Ireland, was interesting. The land is mostly owned in large tracts by "nobles" or "lords," and rented out to tenants. The fields are small, and divided by hedges. The country houses are mostly but one low story high, the walls of dried mud, or stone, and covered with thatch, that is a thick layer of straight straw, for a roof. The people appeared contented, but exhibited none of that activity and enterprise manifested in America, where most farmers *own* the land they till. There is considerable hilly and waste, or very poor land. I first saw, here, the digging of turf for fuel. Many women and children (few men) were out cutting up the turf into nice blocks of small size, and piling them up to dry, for burning in the houses. The turf is like the black earth of our swamps, but much more compact or solid. On a single acre there were sometimes 30 to 50 families piling up their heaps.

Approaching Belfast, the great linen town or city, we saw hundreds of acres of grass covered with linen cloth bleaching in the sun. Our finest white linen is woven in the brown state, and bleached afterwards. Flax is largely grown in the neighborhood of Belfast. The manufacturers send it out many miles into the surrounding country to be spun, and much is spun and woven by machinery in the city. I visited one mill where 1,600 men, women, and children were preparing and spinning and weaving flax—people enough for a large village all in one establishment. Much of the linen used in our country comes from Belfast. The great Linen Hall, and the celebrated Ardoyne Mills, where are woven our finest damask table covers, were exceedingly interesting, but it would require too much room to describe them here.

In my next letter I purpose to tell something about Scotland, and the great City of London.

THE STEPPING STONES.—FROM A PAINTING BY J. J. JENKINS, ENTITLED "COME ALONG."

Engraved for the American Agriculturist.

The scene, our young readers will perceive, is one of mountain peasant life. The back ground is charming, the stream widening to a lake, the birds hovering over the quiet waters and the distant mountains. "What a nice place to bathe," we hear some exclaim, and others, "There must be trout in that lake, the waters are so clear." Some will anticipate a little, and think of skating and cutting ice.

But there is something more charming here than the features of the landscape, and even the young folks, who are so full of play, will see it when they look at the faces of the mother and her child. They have been away all day in the grain fields gleaning. The little girl has been helping, and a part of that goodly bundle of wheat is the result of her industry. They are crossing the ford that leads to their home, a place she has been carried over so often, that she thinks she must have help. You see her fear, and the suppressed smile of the mother (whose hands are occupied with the bundle), encouraging her to take the step, and she must help herself or be left behind. The artist has told the story well, and it is for our young readers to apply the moral. —There is a time, but a little while ahead with most of our young readers, when you can not have the help of your parents. They have provided for all your wants, fed you, clothed you, taught you, and done it with so much kindness and apparent pleasure, that you have never suspected how much self-denial and labor were involved in your comfort. You could not live without them, and yet you must soon learn the lesson taught the child in the picture, to *help yourself.*

Parents see and feel this more than you do, and so they lay tasks upon you. Had they always carried you in their arms, you would never have learned to walk. And the habit of self-support, that you are acquiring under the guidance of your parents, will soon enable you to take care of yourselves.

And there are lessons in the picture for our older readers—that mother evidently has confidence that her child will take the steps, and get over safely, and when the little one sees that look of confidence and encouragement in her face, it is worth a thousand warnings to her—she will be as brave and as sure-footed as her mother thinks her. We know of parents who do not expect much of their children. They fret over their short-comings, and have no patience to teach them better. They treat them as if they did not think them capable of doing well, and the result justifies their expectations. If that mother screamed at the child that the water was deep and the rocks slippery, and the current swift, and that she must take care, and acted as if she did not believe she would get over safe, would the little thing have the pluck to venture? Probably not, and if she did she would be very likely to slip.

How powerful is the influence of example. The mother passes on before—the daughter, timorous, yet strong in confidence in the mother, follows on the slippery way across the water. "Come along," the mother says, and so the artist named the picture. Yes, follow thy mother child, in her diligence and frugality, and in all her moral virtues, as well as her sure-footed way across the mountain stream. Be strong to do as she says; be independent to do right, even though unaided and alone. Mothers, so lead your children in safe, right ways, that you can trust them in those things calculated to try their courage and their principles. Then heartily give them that confidence, with your own example, which gives both moral and physical power.

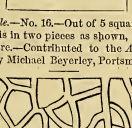
About Kites.

Who ever saw a boy that did not enjoy kite-flying? We never did. It was one of the very pleasantest sports of our boyhood, and we hope all our young readers, particularly the boys, enjoy it too. The kite is a toy which depends upon very philosophical principles. And there is a good deal of skill required to make a good kite and fly it well. This is just the time for kite-flying, for the grass is mown, and the grain is much of it harvested, so that the fields are clear, and there is room enough to raise the kite without doing any injury. A good kite is strong and light—and of such a shape that a great surface is exposed to the wind, in proportion to the amount of wood in the frame. A square kite, or a diamond-shaped one, or a six-cornered one, are each better than a bow-kite, because there is so much wood in the bow, that it is hard to make a bow-kite that will fly well in a light breeze. Whoever makes a kite should take care to make it perfectly symmetrical—that is, just the same on one-half as on the other, just as heavy, and to look the same. Select straight-grained pieces of pine wood, have them of very even size throughout, somewhat flat, and without splits; as light as you think they will do. For a square kite, cross two pieces of equal length at the middle of each. Tie them together with shoemaker's "waxed ends" if you can get them; they will not slip—and it is not best to cut notches or nail them, for this weakens the wood. Then take a stout linen cord, and having notched the sticks on the ends, pass the string around, and tie it as tight as you can and not split or make the sticks bow, and drive a small carpet tack into each end through the string. Next make some paste—which is done thus: Take a tablespoonful of flour, put it in a teacup, and wet it with a little *cold* water, and stir it up till it is as thin and smooth as cream—then stir it slowly into about a teacupful of boiling water in a tin cup, which is kept boiling. This will make a beautiful, smooth, clear paste, and if you stir some fine salt or powdered alum into it, it will keep a long time. When the paste is made, spread a newspaper out on the clean floor, or upon another paper, and lay your kite-frame upon it, then cut the paper about an inch larger all around than the cord. Beginning on one side, spread a thin coat of paste on the edge of the paper, and paste it over the cord; then do the opposite side; then cut the paper at the corners so that it shall fold smooth, and paste the other edges; and finally paste several narrow strips of stout paper across the sticks to keep the paper from tearing off or rattling. Care must be taken to have the paper very smooth and tight, and if the paste is strong, it answers sometimes to dampen the paper slightly but evenly when it is pasted. It will then be tight as a drumhead. To make a diamond-kite, have one stick about ⅗ as long as the other, and let it cross ⅖ from the top of the long one. Otherwise make it like a square kite. A six cornered kite has usually two long sticks of equal length crossed, and one a little shorter, crossing at the same point, which is above the middle of the kite. The prettiest way to arrange them is so as to have the two upper ends of the long sticks, above where they cross, just as long as the ends of the cross piece, and the distance between the lower ends of the long pieces, not so wide as the cross-piece is long.

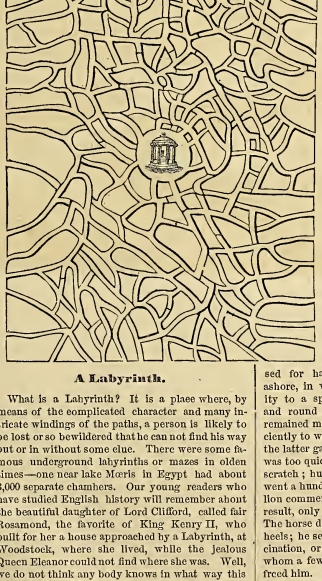
Fasten the line to strings tied to the sticks, going through the paper, so that it may be slipped up and down, and the amount of wind the kite holds may be regulated in this way—the higher it is "hung" the less wind it will hold, but the more it will take to hold it. It must always be hung above the middle, or it will not go up. Woolen list, which may be got at the tailor's for little or nothing, makes the best tails—the length of which must be regulated according to the strength of the wind—and so must the strength of the line also, for a light line will do very well in a nearly still day, but when the wind blows hard, the line must be strong, or the fruits of much labor will be lost. We shall have more to say about kites, and lanterns to send up attached to them, at another time, but now, will only caution you not to make too large ones.

For the Guessers.

Illustrated Rebus.—No. 15.—Above is a Rebus which is a very good one, but it will tax the ingenuity of a very good guesser to solve it. Still some parts of it are very easy, and by patience, we think, it may all be worked out.



Block Puzzle.—No. 16.—Out of 5 squares like this one, which is in two pieces as shown, construct a perfect square.—Contributed to the *American Agriculturist* by Michael Beyerley, Portsmouth, Ohio.



A Labyrinth.

What is a Labyrinth? It is a place where, by means of the complicated character and many intricate windings of the paths, a person is likely to be lost or so bewildered that he can not find his way out or in without some clue. There were some famous underground labyrinths or mazes in olden times—one near lake Moeris in Egypt had about 3,000 separate chambers. Our young readers who have studied English history will remember about the beautiful daughter of Lord Clifford, called fair Rosamond, the favorite of King Henry II, who built for her a house approached by a Labyrinth, at Woodstock, where she lived, while the jealous Queen Eleanor could not find where she was. Well, we do not think any body knows in what way this labyrinth was constructed; but we have received the accompanying sketch of Fair Rosamond's labyrinth, and though the bower in the center in which she is said to have lived has been changed to a temple of Liberty, we think it will please and perhaps puzzle some of the boys and girls to find their way in without crossing a line.

The Play of the Elements.

This is one of those games which sharpen the wits and promote sociability. It may be familiar to some of our young readers, but probably not to many of them. Our young friends know from what we have told them about elements, that air and earth are not elements at all. Yet the Ancient Philosophers considered them so, stating that there were four elements, fire, air, earth, and water, so these are often called *the elements*. The same game is often played and called "*Fish, flesh, fowl.*"

"Let the company sit in a circle; when all are prepared, the beginner of the proceedings takes a handkerchief, and, looking at some one as if he were about to throw it at him, darts it at another, crying "Air!" or (whatever element he chooses, air, earth or water,) "one, two, three. four, five, six, seven, eight, nine, *ten!*" The other, if he be ready-witted, will answer before the numbers are over, "sparrow," or the name of some other inhabitant of the "element" named; but often when taken by surprise, he will stammer, remain in a state of stupid perplexity, or give the name of a four-footed beast as an inhabitant of the air. If he makes a mistake, he pays a forfeit, but at any rate throws the handkerchief in his turn and soon meets with plenty of companions in misfortune, whose forfeits in a pile on the table must shortly be redeemed. This play creates much amusement, and quickens the wits."
MRS. J. F. JENNINGS, Brighton, Mich.

The Horse and the Lion.

The following interesting anecdote is from an article which appeared some time since in Blackwood's Magazine:

"There were some horses on board belonging to Major Kemball, the Consul General at Bagdad, one of which got loose and leaped overboard just at dawn. The steamer was then about half way to Bagdad, and getting under way, after anchoring as usual for the night. The horse was not missed for half an hour, but was then descried ashore, in what seemed very unpleasant proximity to a splendid lion. The lion circled round and round him, always closing in. The horse remained motionless, beyond turning his head sufficiently to watch the lion's movements. Suddenly the latter gave a tremendous bound, but the horse was too quick for him, and escaped with a slight scratch; but instead of galloping away, he only went a hundred yards, and again stood still. The lion commenced his former tactics with a similar result, only his bound was less vigorous this time. The horse did not even yet take completely to his heels; he seemed either tied by some strange fascination, or inclined to tantalize an enemy from whom a few minutes' canter would have entirely freed him. Again the lion commenced his circles, but ere they were narrowed to springing distance a party had landed from the steamer, and the instant the horse had descried them he came galloping down, while the lion stalked away toward the jungle."

The Crop Reports and the Market—Weather, etc.

Our crop reports represent a very flourishing condition of the country, agriculturally speaking. The grain crop is decidedly in advance of last year's, though that was very great. Corn alone of the cereals falls behind. There are now very encouraging market prospects, indicating a certain demand for American breadstuffs. Naturally, this would tend to fix the price of wheat, at least in men's minds, but the state of the money market is such that it is impossible to name any figures which can be regarded as the probable price. The difference between gold and paper money is now so enormous, and there being no way to tell how long this state of things will last, that other values are very uncertain, and will continue to be until the relations of trade are less disturbed and a more settled state of the money market prevails.

THE WEATHER has been prevailingly favorable over the whole country, except North-eastern New-York and Northern New-England, where, up to our last advices, a severe drouth prevailed. Late in June (17th to 20th,) frosts of considerable severity visited Central New-York, some parts of Pennsylvania, and the West, doing much damage, but only in quite limited sections. The insect pests are making their accustomed havoc here and there. The cherries, grains, etc., suffered from the aphis—various caterpillars have been abundant, the chinch bug has done great damage in spots, and so has the midge, and in Colorado the grasshopper (or locust) has swept some districts, but no wide-spread desolation has occurred by drouth or wet, moth or rust.

GENERAL AVERAGE.—An average of each column is given at the foot of the table. Taking *prospects* alone exclusive of the fruits, we find an improvement over June; **10.8** being the average for July, against **10.3** in our last report. This is due to the wheat crop being successfully gathered. The general average of all crops, except fruits, including breadth, prospects, etc., is **11.8** and including fruits it is **12.8,** better than even the May report. The general average for the three months thus far reported; runs, May **12.6**, June **12.2**, July **12.8**.

Reports on Crops, July 10, 1862.

(See General Remarks and Reports on Special Crops on page 232.)

NOTE TO REPORTERS.—It is very important that a large number of the reports be mailed earlier than heretofore. It is useless to put two rows of figures, for we are obliged to average them afterward. It is also perplexing to have the words *fair, good, pretty good, poor,* etc., used instead of figures. After a crop is harvested, please estimate it, and mark figures as usual.

EXPLANATIONS TO THE READER. (Full details are given on the Blank Forms furnished to Reporters.)

The First Column gives the Counties from which the reports come. In many cases the territory reported upon extends over adjacent counties, and the figures apply to a larger territory than the county named, but sometimes to single townships only.

The Second Column gives the number of persons in each county or locality, the average of whose opinions are embraced in the single rows of figures, standing opposite in the same line. In several cases a whole County is represented by an officer of the Agricultural Society, who gives the summary of reports from assistants in each of the towns *m* indicates that a large but indefinite number of persons joined in making the report.

The Third Column gives the names of the persons who received and distributed blanks, and collected and forwarded returns.

☞ *In all the reports the numeral* **10** *is taken as the standard for comparison,* thus:

Column A—10 means that the weather for a month previous to the date of the report was about as good as the average for other years, that is for growing crops and for general farm operations. Figures above or below **10** indicate the comparative propitiousness or unfavorableness of the weather.

Columns—B—E—H—In these **10** indicates that the amount of surface growing is about the same as *last year.* Each figure (or unit) above **10** means a tenth more of surface, and each unit below **10**, means one-tenth less. Thus, 5 means one-half of average surface—**15** means one and a half—**20** means double, and so on.

Columns C—F—I—L—N—P—S—In these columns **10** means that the average surface sown or planted or growing is about the same as the average for five years past. Each unit above or below **10** stands for an increase or decrease of one-tenth in the surface.

Columns D—G—K—M—O—R—T—U—V—In these columns **10** means that the *conditions* and *prospect* on June 10th indicated an *average yield per acre.* Here also each unit above or below ten indicates the prospect of a yield a tenth above or a tenth below the average; thus, a half crop is indicated by **5**—a double crop by **20.** Some report fruit prospects at **100** to **300**, meaning that the promise is for ten to thirty times the average.

Blanks left in a column indicate that little or none of the crop is grown, or that it is so early to report upon it, or that the reporter could not estimate satisfactorily to himself. No reports have been received from some whose names are in the list, and who furnished reports last month.—For comments and reports on other crops see page 260.

OPERATIONS AT VICKSBURG.—The map shows the City of Vicksburg, Miss., on the eastern side of a large bend in the Mississippi, and the track of the canal now nearly completed, through which at the first rise, it is expected the waters will form a new and permanent channel, thus opening the navigation of the river.

Market Review, Prices, etc.

Heavy receipts and sales of Breadstuffs have been reported, during the past four weeks. The weather and market news from England have been encouraging to export buyers, who have purchased freely, in anticipation of an extensive deficiency in the yield of the harvest in the British Islands. The rapid advances in the value of Gold, and in the rate of Sterling Exchange, has also stimulated the demand from shippers, as it gave them unusual advantage in executing their orders. Toward the close of last week export movements were checked by the rise on freights, and a strike among the grain shovelers, who refused to work in connection with grain elevators. This difficulty is now partially adjusted, and many of the laborers have concluded to resume work. The home trade inquiry has been good, The annexed table of prices indicates a very general and gratifying improvement in the market value of the principal kinds of Breadstuffs. Flour has advanced 25@50 cents per bbl.; wheat, 10@15 cents; rye, 3 cents, and oats have risen 3@4 cents per bushel; corn has fluctuated considerably, but closes with an upward tendency....The rise in Cotton has heen very rapid, amounting to 16 cents per lh., and sellers still have the advantage, the demand being largely in excess of the available supply. The receipts have averaged about 2,000 bales a week, while the weekly sales and re-sales have run up to an average of 6,500 bales....The supply of Provisions has been ample, and the market generally depressed, until within a few days, during which period hog products have been more sought after at advancing prices ...Hay has been quite plenty and in very moderate request at slightly reduced rates....Hops and Tobacco have been in fair demand and have been quoted very firm....Rice has been scarce and wanted; it closes higher....Wool was inactive early in the month; but, during the past ten days, has been quite freely dealt in and has increased in value. The market closes briskly. In the country there is less excitement, but high prices continue to be sustained. In fact, higher prices have been paid in the country than could he realized if forwarded here for sale. The bulk of the clip has been bought up.....The transactions in other agricultural products have been on a moderate scale. The table of prices show the changes and the present rates.

CURRENT WHOLESALE PRICES.

N. Y. Live Stock Markets.—THE CATTLE MARKETS have been fully supplied during the past month and there has been a slight decline in prices. Most of the stock now hails from Illinois, and is of fair quality, corn-fed last Winter and grazed this Summer on the rich prairies. For the first week (June 24) we had 4,427 bullocks all of which were sold at about the rates of the previous week, or an average of 8c. per lb. for the estimated weight of the dressed carcass. The following week there were 5,187 cattle, which was 300 more than could be sold even at a decline of ⅛c. per lb. Graziers bought several droves for feeding along the Hudson River and Harlem railroads. The first week in July showed 4,250, which, taking into account those left from the previous week, and the fact that butchers then hought more than they wanted, proved some 250 more than were needed. Prices a shade lower still, with a slow market. At the last market, July 15, present 3,550 beeves, which an active demand soon used up at an advance of ⅛c., and a few hundred more could have been sold. Prices for prime steers were 8¼c.@8½c. ℔ lb.; fair cattle, 7½c.@8c.; poor stock, 7c., with a general average of 7¾c. for all kinds, the quality ranking only medium. Average weekly receipts, 4,354.

Veal Calves.—Receipts continue to fall off as the season advances, and the demand for veal is proportionally less. They are worth 3½c.@5½c. per lb., live weight, very few bringing the latter price. Good calves sell at 4½c.@5c. per lb. The average receipts for the past four weeks amounts to 587, or near 200 less than last month.

Sheep and Lambs.—Receipts have been much larger than last month, the weekly average being 9,885, but as mutton is a favorite food during hot weather, the demand has exceeded the supply, at least for two weeks past. Good sheep of 90 lbs. to 110 lbs. weight, alive, are worth 4c., and if really fat, 4¼c. Medium and thin stock sells at 3¾c. down to 3¼c. Lambs bring 5½c.@7c. per lb., approaching the price of sheep as they gain size and age.

Live Hogs.—Receipts are light just now, the number for the past week (5,871) being less than for any previous week since last September. The average receipts for the month are 8,690, against near 10,000 for the previous four weeks. Prices have ruled very low, reaching, July 8, the lowest point in ten years, with 9,560 on sale, following the large number of 12,900 the previous week. They fell to 3c. for prime corn-fed hogs. At the last market there was a marked advance in view of light arrivals, and fat corn hogs brought 3¾c., and still-fed hogs 3¼c. All sold.

The Weather has generally been warm, and during the last two weeks, rather dry. The crops are now looking well, and the hot weather has greatly changed the appearance of the corn, which was kept back by drouth, cold, and lastly too much rain. The berry crop is being diminished in some places for lack of rain, but on the whole there is every prospect of an abundant harvest of crops not gathered as will be seen by reference to our crop statistics on page 250. OUR DAILY NOTES, condensed, read:——*June* 21, 22, clear and fine—23, clear, with N. E. rain storm at night, which continued during the day and night of 24th—25, cloudy A. M., showers P. M., and at night—26, cloudy A. M., clear P. M.—27 to 29, clear, fine, hot, growing weather—30, light rain A. M., clear P. M.——*July* 1, clear, fine—2, N. E. rain storm P. M., and at night—3, cloudy A. M., clear P. M.—4 to 7, clear, hot days, the mercury reaching 90° in the shade—8, showers A. M., clear P. M.—9, 10, warm, light showers each day—11, 12, clear and fine, but cool—13 to 15, clear and hot, excellent corn weather, getting dry, with light shower at night of 15th—16, clear and hot, heavy thunder shower at night, soaking down thoroughly and doing abundance of good—17, 18, clear, and fine.

Rain Fall.—From the 15th of June, to the 15th of July, there were 4.38 inches of rain, which fell at 6 different times, besides 4 other slight showers which could not be measured.

Thermometer at 6 A. M., New-York.

Observations carefully made upon a standard Thermometer (Fahrenheit.)—+ indicates rain, ; snow.)

Agricultural and Horticultural Tools of every description.

Treatise on Sorghum Wine,
WITH
A RECIPE FOR MAKING IT,

Now offered for sale. I will dispose of Individual, Manufacturers, County and State Rights.

Sorghum wine has taken the country by surprise, not only on account of its production from this plant, but its superior quality. It has been examined at the State Sorghum Convention, at Ohio, Columbus, 1862, and highly recommended. It has been exhibited to wine connoisseurs in Columbus, Cincinnati, Springfield, Cleveland, Ohio, and Philadelphia, Baltimore and Washington. It has not only surprised them but received the highest encomiums and premiums. It has been used by Physicians in cases of sickness with entire satisfaction, because of its purity and healthfulness. And strangers, some of whom have been restored to health by the use of a few gallons, have given flattering testimony of its beneficial effects.

RECOMMENDATIONS.

From Hon. William B. Hubbard, of Columbus, O., President U. S. Agricultural Society.
Columbus, March 31, 1862.

Rev. A. Myers—Dear Sir: The sample of Sorghum Wine, left by you with me, has been submitted to different wine judges, who have visited my house, and, without exception, has met with decided commendation. Most of them pronounce the aroma, or fragrance, of your Wine that of the cherry, the majority that of the peach. It is a delicate, fairwine, and destined, no doubt from the ease and cheapness of its manufacture to become an item of value to the manufacturer and cultivator.
Yours truly,
W. B. HUBBARD.

From Mr. D. M. Cook, of Mansfield, O., Patentee of Cook's Portable Evaporator.
Mansfield, O., March 15, 1862.

Rev. A. Myers—Dear Sir: I have used your Wine, made from the Sorghum cane, and I learned with regret that that your Sorghum Wine is most delicious, and that it would be difficult to distinguish it from the best Madeira. Truly,
Hoping that you will not fail to introduce your work on Sorghum, as also your Wine to the public soon,
I am truly your most obedient, D. M. COOK.

THE RIGHTS OF MANUFACTURERS SUPPLIED.

1. An *Individual Right* embraces the privilege of manufacturing all the wine he can for his own family. Price $1.00.

2. A *Manufacturer's Right* is to manufacture and sell. To manufacture all a manufacturer of Sorghum Syrup can while he is manufacturing Syrup, from the middle and last pressings and inferior Syrup for his own use and for sale. Price from $2.00 to $5.00.

3. A *Township, County or State Right* embraces the exclusive privilege of manufacturing and selling wine in said limits.

REFERENCES.—As a guarantee of honesty and ability to perform all I agree, I refer to the President and Professors of Wittenberg College, Springfield, O.; any of the citizens of this city, or Bucyrus, O., and all the English Lutheran Ministers in the State of Ohio, especially those in Miami and Wittenberg Synods.

Persons desiring the use of this recipe, and indicating the privilege they desire, and sending the amounts to me by mail, or by express exceeds $5.00, by Express or draft, will receive by return mail the certificate of right, and about the first of Sept. the recipe. Every subscriber will be required to state in writing his secrecy which he will receive with the certificate of right to be returned to me when signed. This is required to secure to me my right as inventor. Honest men will not hesitate to comply, and with distressed ones I wish to sympathize. Any information desired, in any community making up a club of Ten or more subscribers will be satisfactorily rewarded. Address A. MYERS,
Springfield, Ohio.

THE AMERICAN PUMP.—The best pump for the cistern, wells, fire, and power. Drawings and prices free. J. M. EDNEY, 1005 Broadway, New-York.

WHEELER'S COMBINED THRESHER AND CLEANER.
BARGUS'S PATENT CLEANING ATTACHMENT.
HORSE POWERS, FAN MILLS, &c.
Circulars, containing List of Prices, Testimonials, &c., will, on application, be sent by mail. Address
GRIFFING BROTHER & CO.,
60 Courtland-st., New-York.

EXCELSIOR
BURR STONE MILLS.
(FOR FARMERS AND MILLERS.)
AND
ANTI-FRICTION
HORSE POWERS.

Took TEN FIRST PREMIUMS at WESTERN STATE FAIRS last year, and are justly considered superior to all others.

The Mill may be driven by *horse, water, or steam power*, does its work as well as the flat stone mills in milling establishments, and requires but *one-half the power* to drive the largest sizes. They are compact, perfectly simple, and for farm use will last *thirty years*, and *cost nothing* for repairs.

THE HORSE-POWER,

Has proved itself to be the best ever invented. The friction is reduced by IRON BALLS, so arranged in all the bearings, that the whole weight of the castings runs upon them. THREE POUNDS DRAUGHT, at the end of a tenfeet lever, will keep the power in motion! thus permitting the ENTIRE STRENGTH of the horses to be used on the machine to be driven. ONE HORSE will do as much work on this power, as two on the endless Chain Power. IT IS PORTABLE, and may be used IN THE FIELD as well as in the house. More than TWENTY-FIVE PER CENT of horse flesh is saved over ANY OTHER POWER IN USE. It is simple in construction, and not liable to get out of order.

Price of Power for 1 to 4 horses $125
Price of Power for 1 to 8 horses 175

THE $125 POWER WILL DRIVE ANY THRESHING MACHINE. EVERY MACHINE IS GUARANTEED TO GIVE SATISFACTION, OR THE MONEY WILL BE REFUNDED.

Opposite the Astor House,
New-York.

WOODRUFF'S
IMPROVED
WEATHER INDICATOR.

While in this age of invention and progress, our American Farmers have seized with avidity almost every invention and implement of husbandry that Art or Science could bring to their aid, one of the most important auxiliaries—the Barometer—has been almost entirely overlooked. This has arisen partly from a want of knowledge of its value and importance, but principally because the peculiar delicacy of construction, and high cost of the instrument have made it unavailable to the masses. In this instrument these objections have been entirely obviated. While its simplicity of construction, and scientific arrangement, render it perfectly portable and accurate, its cost is so low as to place it within the means of all. Indicating with unerring certainty coming changes in the weather, it also affords a simple and accurate medium for measuring hights, while the accompanying Thermometer gives the temperature. The Scientific American, Profs. Williams, Carr, Holmes, Dowglass, and a host of public Journals and scientific men, recommend it as the *Agricultural Barometer, par excellence.* Profs. Henry, Hackley, Maury, Drs. Arnot and Dick, have computed that an annual saving of five per cent. on all crops might be made by its use, thus affording an annual saving of over fifty million dollars to the farmers of the United States. It is simple, durable, accurate, perfectly portable, and very cheap; is nicely finished, and affords a very beautiful and ornamental piece of furniture; some of the carved cases being very elegant. We give below a brief description of it, from the accompanying cut, in which the cistern is seen divided to show its construction. The cistern, *A*, is of cast iron—cast with two compartments—partly filled with mercury. The tube *C*, filled with mercury, is sealed into the cistern, *A*, and being placed upright, the air is admitted by turning back the screw, *D*, which has a flat place filed in its side near the outer end, where air can pass through the outer wall, when the mercury takes its level, and it is in working condition. To make it portable, turn it over on its side, when the spare mercury runs from *B* to *A*, filling tube and cistern, *A*, full—turn in the screw, and it is shut into *A* perfectly solid, and may be thrown about with impunity, or carried by Railroad or Stage Express all over the world in safety.

We claim for this instrument that while it possesses ALL THE INTRINSIC MERIT of other Barometers, it has several peculiar advantages possessed by NO OTHER, while its construction is such as to avoid the objections to which all other instruments are more or less subject. Among its peculiar merits are:

1st. Its accuracy, being a Mercurial Cistern Barometer, and constructed on strictly scientific principles. It has stood the severest tests of a great number of scientific men, and is amply recommended by eminent scientific authorities who had previously discarded and condemned the Aneroid and other ordinary cheap Barometers. For evidence of this we refer to the U. S. Coast Survey, Smithsonian Institute, and other eminent scientific authorities whose certificates we have.

2d. Its cheapness. While possessing intrinsic merits possessed by none other, its price is lower than any other reliable Barometer.

3d. It is perfectly and entirely portable, and can be expressed by stage or railroad to any part of the country without injury. THERE IS NO OTHER PERFECTLY PORTABLE BAROMETER.

4th. Its thorough construction and perfect simplicity make it the most durable and perfect Barometer ever invented, and renders it impossible to injure or get it out of order, except by gross carelessness or design.

5th. It is unaffected by changes in temperature, which can be said of NO OTHER Barometer.

6th. Its beautiful finish and tasteful design render it a beautiful parlor or library ornament, while it affords a never failing study of interest to the man of leisure, cultivation and refinement, and a sure and reliable indication of the coming weather, to all whose interests are affected by atmospheric changes.

PREMIUMS

Have been awarded it by the New-York, Vermont, Michigan, and U. S. Agricultural Societies over all competitors.

☞ Agents wanted everywhere. Exclusive agencies given.

CHARLES WILDER,
Peterboro', New-Hampshire.

THERMOMETERS and HYDROMETERS furnished.

New and Splendid Varieties of Strawberries.

Empress Eugenie, Margarite, Prince Frederick William, and Victory.

The last is an American Seedling. Fruit of immense size. The other three are the prize varieties of Europe for 1861. Fruit of extraordinary size, weighing from one to two ounces each. The above at $2.00 per dozen, or the four, one dozen each, for $7.00.

The following new and fine varieties La Constante, Wizard of the North, Wonderful, Oscar, Duc de Brabant, Prince of Wales, Honneur de Belgique, Filbert Pine, Crimson Queen, Prince Imperial, Surpass Triomphe, Deptford White, and Duc de Malakoff, at $1.00 per dozen; a selection of six for $4.00, or the thirteen varieties for $7.00.

La Constante can be furnished by the hundred for $4.00. This magnificent berry, after two years trial, has proved to be of great value as a market berry. Fruit very large, fine color, and very productive. A special prize was awarded this variety at the exhibition in Boston last year.

Triomphe de Gand, Bartlett, Downer's Prolific, Jenny Lind, True Chili, and Athlete, at $1.50 per hundred, or $10.00 per thousand. The Downer's Prolific is a fine market berry; it is more productive than the Wilson. Fruit large and a beautiful scarlet color.

Great Austin Shaker Seedling, 30 plants $1.00; 2? per 100; $15.00 per 1000. Not less than one dozen sold of any variety. All orders addressed to

WM. S. CARPENTER, 329 Greenwich-st., N. Y.

Price $3 per dozen; $? per ?0 dozen.

All orders registered as date received.

Plants ready for delivery in the Spring of 1863, and will be sent out in the rotation as ordered.

Address GEO. CLAPP, Auburn, N. Y.

Great Austin Shaker Strawberry.

The berries of this remarkable variety are much larger than any other kind cultivated in this country; it produces enormous crops, and the fruit is very attractive, being of fine scarlet color. The Austin was exhibited at the office of the American Agriculturist last year, weighing one ounce. Nearly 1000 boxes were sent from Watervliet last year, a distance of 160 miles, and sold to Taylor, corner Broadway and Franklin-sts., New-York, for 30 cts. per quart, proving the Austin to be one of the most profitable market berries in cultivation. Our stock of plants is very large and fine, at the following rates: 30 plants $1; per hundred $2.00; per thousand $15.00. We commence delivering plants on the first of August, in rotation as ordered. Address either

CHAUNCEY MILLER, Albany, N. Y., Shaker Trustee, or WM. S. CARPENTER, 329 Greenwich-st., New-York.

THE ILLUSTRATED STRAWBERRY CULTURIST,

BY A. S. FULLER,

Price, "Three Reds and a Blue."

Contains the History, Sexuality, Field and Garden Culture, Forcing or Pot Culture, How to Grow from Seed, Hybridizing; results of extensive experiments with Seedlings; different modes of Preserving, Cooking, and Preparing Strawberries for the table; and all other information necessary to enable everybody to learn how to raise their own Strawberries. Together with a full description and the relative merits of new varieties, and a list of the best of the old sorts. Fully illustrated by new and valuable engravings.

The above will be sent by mail, post-paid, on receipt of ONE DIME. Address

A. S. FULLER, Brooklyn, N. Y.

THE BEST TEXT BOOK.

PROF. ALPHONSO WOOD'S NEW CLASS BOOK OF BOTANY, being outlines of the Structure, Philosophy, and Classification of Plants, with a Flora of the United States and Canada. New and enlarged edition. later, 12mo., 376 pp. Price $2. Published by A.S. BARNES & BURR, 51 and 53 John st., New-York.

BAKER'S PATENT FRUIT JARS.

SIMPLE, RELIABLE, AND CHEAP.

They combine the advantages and yet avoid the defects of other jars.

Potter & Bodine,
MANUFACTURERS.

No. 48 Vesey-st., New-York. & No. 106 Chestnut-st., Philadelphia, Pa.

Wheeler & Wilson's SEWING MACHINES
AT REDUCED PRICES.

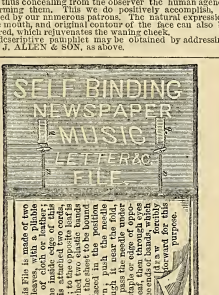
WITH GLASS CLOTH PRESSER, IMPROVED LOOP-CHECK, NEW STYLE HEMMER, BINDER, CORDER, etc.
Office No. 505 Broadway, New-York.

"This Machine makes the 'LOCK-STITCH,' and ranks highest on account of elasticity, permanence, beauty, and general desirableness of the stitching when done, and the wide range of its application."—*Report of American Institute, New-York.*

TEETH
UPON ALLEN'S SYSTEM
CAN BE OBTAINED AT
22 Bond-st., New-York.

By this method the TEETH, GUMS, ROOF, and RUGÆ of the MOUTH are all truthfully represented, reflecting those delicate tints, shades, and forms peculiar to the natural organs, thus concealing from the observer the human agency in forming them. This we do positively accomplish, as evinced by our numerous patrons. The natural expression of the mouth, and original contour of the face can also be restored, which rejuvenates the waning cheek.

A descriptive pamphlet may be obtained by addressing DRS. J. ALLEN & SON, as above.



These convenient Portfolio Paper Files are for sale at the office of the *American Agriculturist*. They are of various sizes, from the large folio to small octavo.

SHOW, SALE, AND LETTING OF SOUTH DOWN SHEEP.

My 12th annual sale of yearling rams, ram and ewe lambs, and FIRST PUBLIC LETTING, will take place (D. V.) on Wednesday, Sept. 30, 1863, at 2½ P. M. Most of the yearlings by "*Excelsior*" (the lambs by "*Excelsior*" by "*Mr. 39*" (the $1000 ram), and "WEBB'S FAVORITE YEARLING." From Philadelphia, persons will take the early morning train (Camden and Amboy R. R.) for Freehold, and carriages to the farm.

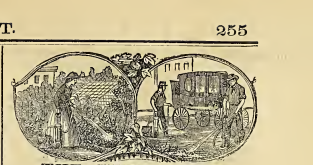
From New-York a steamboat will leave the foot of Robinson-st. for Keyport, at which point carriages to go to the farm will be in readiness. Returning the boat will reach New-York about 8 P. M. Please send for circular, pedigrees, &c.

J. C. TAYLOR, Holmdel, N. J.

FOR SALE.—FULL BLOOD SOUTH-DOWN BUCKS at reasonable rates. Apply by mail to H. E. LIVINGSTON, Tivoli, Duchess Co., N. Y.

ITALIAN QUEEN BEES.

We *guarantee* the *purity* of all Queens bred by us, and their *safe arrival* at any Express Office. Price for a Queen of a *beautiful color* in a small box with few workers, $10.00; or $5.00 when not *warranted* to be impregnated by an Italian Drone. Ministers of the Gospel are entitled to use "Langstroth's Movable-Comb Hive," without charge, and can have warranted Queens at $5.00. L. L. LANGSTROTH & SON, Oxford, Butler County, Ohio.



THE HYDROPULT,
THE GREAT PATENT OF THE AGE.

The most available Fire and Garden Engine in the world. See American Agriculturist for March and June, 1861. Price $12.00. Liberal discount to agents. Please call and examine it at 254 Broadway, or send for Circular.

Grover & Baker's CELEBRATED NOISELESS SEWING MACHINES.

Acknowledged to be superior to all Others.

495 *BROADWAY, NEW-YORK.*

"Grover & Baker's is the best."—*Am. Agriculturist.*

FOR SEWING MACHINES.

FARMERS' WIVES

We respectfully ask you to try our goods, viz.:
PYLE'S DIAMOND SALERATUS.
PYLE'S GENUINE CREAM TARTAR.
PYLE'S PURIFIED SODA.

These articles are entirely pure and wholesome, besides we give sixteen ounces to the pound every time. We know that some do not, but make fourteen by short weight. Give us a trial, and you will be satisfied. Tell the Grocer you want **Pyle's Saleratus. Pyle's O. K. Soap** is also the best Soap in the world for Household use.
Sold by Grocers generally.
JAMES PYLE, Manufacturer,
Corner Washington and Franklin-st., New-York.

WASHING MACHINE.

The "Nonpareil" is the only reliable one in use. Send for Circular to CARLEY & SPEARING, 59 South-st., New-York.

GENUINE
SUPER-PHOSPHATE OF LIME,
Manufactured from **Raw Bones,** dissolved in *Sulphuric Acid at $45 per ton,* by
A. LISTER & BROTHER, TARRYTOWN, N.Y.
(For results of the past season see *American Agriculturist*, for August, 1861, page 252.)

We guarantee every ton of our manufacture to be of uniform quality, and to yield results of celebrated analysis.

We also manufacture from RAW, (OR UNDUNED), BONES, the fine, medium, and coarse ground **Bone Manure,** for lasting as well as immediate effect upon all kinds of farm crops. The coarse ground is particularly valuable for *Fruit Trees* and *Grape Vines,* which require a constant and lasting source of nourishment.

For sale in large and small quantities by
A. LISTER & BROTHER, Tarrytown, N.Y.
and their agent, F. LANGMAN, 139 Water-st., New-York.

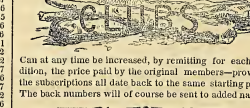
The Postage on the Agriculturist is positively only Six Cents a Year.

We hear that several Post Masters are charging 12, 18, 36, and even 72 cents a year on the *Agriculturist*. This is wrong. The law expressly says that a Periodical issued at stated periods, and not weighing over 3 ounces avoirdupois, shall be charged *one cent* per number, and only *half* this sum if paid quarterly in advance. The paper for the *Agriculturist* is purposely manufactured so that it shall weigh a little *less than three ounces*. We could add an occasional extra page for more advertising room, could we do so without increasing the postage to our subscribers. The Postmaster General has several times decided that postage on the *Agriculturist* is only six cents a year. See one of these decisions on page 96, volume XVII. There has been no change in the law or in the weight of the paper since. The paper must be weighed *any, and at the pleasure of the postmaster*. Subscribers will please promptly inform us of any future over charge.

Mail-Lost Numbers Supplied.

It is hard for the Publisher to alone bear all the losses arising from the carelessness or over-sight of any of the 16,000 Postmasters and carriers who have the handling of the *Agriculturist* between the office and the subscribers. But since Uncle Samuel monopolizes the carrying business, and won't stand any losses, and we can't compel him to, we shall cheerfully send a second copy of any number when the first one mailed fails to reach its proper destination, on being notified of the fact.



Can at any time be increased, by remitting for each addition, the price paid by the original members—provided the subscriptions all date back to the same starting point. The back numbers will of course be sent to added names.

An American Exhibition
OF
Pumpkins, Squashes, and Ornamental Gourds.

There will be a Public Exhibition of **Pumpkins, Squashes, and Ornamental Gourds**, at the office of the *American Agriculturist*, 41 Park Row, New York City, opening on Wednesday, Nov. 5th, 1862, at which the following prizes will be paid by the Publisher, upon the official award of competent Committees.

CASH PREMIUMS.

I. For the *Heaviest* Pumpkin or Squash.....**$20.00**
II. For the 2nd do. do.....**10.00**
III. For the 3d do. do.....**5.00**
IV. For the Best do. do. for cooking.**10.00**
V. For the 2nd Best do. do. do. ..**5.00**
VI. For the largest yield on a single Vine.*..**10.00**
VII. For the 2nd do. do. do. *.....**5.00**
VIII. For the largest and finest collection of Fancy or Ornamental Gourds*.....} **10.00**
IX. For the 2nd do. do. do. *.....**5.00**

*All to be grown by one person and to be accompanied by an affirmed statement from the grower, and two disinterested persons who assist in gathering the specimens.

Note 1—The specimens competing the Prizes will remain on Public Exhibition at the pleasure of the Publisher who offers the prizes. The other specimens will be subject to the order of the exhibitors, or they will be sold at Auction or otherwise disposed of, for their benefit.

Note 3—All Exhibitors must notify us of their intentions by Oct. 25th, and deliver specimens for competition on or before Nov. 3d. Specimens to be delivered free of charge.

American Agriculturist in German.

The AMERICAN AGRICULTURIST is published in both the English and German Languages. Both Editions are of the same size, and contain, as nearly as possible, the same Articles and Illustrations. The German Edition is furnished at the same rates as the English, singly or in clubs. A club may be part English, and part German.

Bound Volumes—Binding—Covers.

We have complete sets of Vols. 16, 17, 18, 19, and 20, both unbound, and bound separately in neat covers with gilt lettered backs.

PRICES AT THE OFFICE.

Volumes 16, 17, 18, 19, and 20, *unbound*.....$1.00 each.
Volumes 16, 17, 18, 19, and 20, *bound*.....$1.50 each.

PRICES WHEN SENT POST-PAID BY MAIL.
(They can not go unpaid.)

Volumes 16, 17, 18, 19, or 20, *unbound*.....$1.12 each.
Volumes 16, 17, 18, 19, or 20, *bound*.....$2.00 each.

BINDING.—Sets of numbers brought to the office will be bound up neatly in our regular style of binding the *Agriculturist* for 50 cents a volume.

PREPAID COVERS.—Covers for binding, neatly made, with title, etc., gilt upon the back, ready for the insertion of the sheets by any bookbinder, can be furnished for Vols.13, to 20 inclusive, at 25 cents per cover. *Covers can not go by mail.*

A CONSTANT EXHIBITION.

The Tables at the Office of the *American Agriculturist* have constantly during the season novel and interesting **Fruits, Flowers, Grains, Vegetables, etc.,** contributed by SUBSCRIBERS, NURSERYMEN, GARDENERS and others, and almost uniformly present a very attractive and instructive exhibition. It has been suggested by some of the horticultural gentlemen of this city and neighborhood that it would be very agreeable to them if we could make it convenient to have

A WEEKLY EXHIBITION,

appointing a *certain day* whereon our friends might come with the expectation of seeing one another, and talking over their choice fruits, etc. This is very agreeable to us, and while we are most happy to receive contributions to our *Exhibition Tables* EVERY DAY, we will name

Thursday of each week

as a convenient day for a special show of FRUITS during this and the following two or three months; on which days we shall be especially happy to see our friends, who are at all times most heartily welcome.

Our tables are spacious, and the office large and airy, and the best care will be taken of the articles contributed.

Persons wishing to become familiar with the best fruits in their seasons, will find it to their advantage to call and examine our tables. The articles are all labeled, with the name of the grower attached, and we need hardly add the exhibition is *free* to all contributors and visitors.

$100 IN PREMIUMS
FOR
NORTHERN GROWN COTTON.
Another Interesting Exhibition
AT THE OFFICE OF THE
American Agriculturist, 41 Park-Row.

One Hundred Dollars are offered for the best five spec imens of cotton grown above latitudes 38° and 40°, the present year, as follows: For 10 lbs., (unginned,) grown north of latitude 40°, 1st prem., $30; 2d $20; 3d $10. For 10 lbs., (unginned,) grown north of latitude 38° and south of 40°, 1st prem., $25; 2d $15. The samples on which premiums shall have been awarded, will be retained on our exhibition tables for the inspection of the public. All others will be subject to the direction of the exhibitors, at the close of the Exhibition. For particulars see February number *American Agriculturist*, page 64.

American Agriculturist.

For the Farm, Garden, and Household.

A THOROUGH-GOING, RELIABLE, and PRACTICAL Journal, devoted to the different departments of SOIL CULTURE—such as growing FIELD CROPS; ORCHARD and GARDEN FRUITS; GARDEN VEGETABLES and FLOWERS; TREES, PLANTS, and FLOWERS for the LAWN or YARD; care of DOMESTIC ANIMALS, &c., &c., and to HOUSEHOLD LABORS. It has also an interesting and instructive department for CHILDREN and YOUTH.

A full CALENDAR OF OPERATIONS every month.

THREE to FOUR HUNDRED, or more, illustrative ENGRAVINGS appear in each volume.

Over TWELVE HUNDRED PLAIN, PRACTICAL, instructive articles and useful items, are given every year.

The Editors and Contributors are all PRACTICAL WORKING MEN.

The teachings of the AGRICULTURIST *are confined to no State or Territory, but are adapted to the wants of all sections of the country—it is, as its name indicates, for the whole* AMERICAN CONTINENT.

TERMS—INVARIABLY IN ADVANCE,
(For either the English or German Edition.)
One copy, one year.....$1 00
Six copies, one year.....5 00
Ten or more copies one year....**80** cents each.
☞Add to the above rates: Postage to Canada, 6 cents; to England and France, 24 cents; to Germany, 36 cents.

Postage anywhere in the United States and Territories must be paid by the subscriber, and is *only six cents a year*, if paid in advance at the office where received.

All business and other communications should be addressed to the Editor and Proprietor,

ORANGE JUDD, **41** Park-Row, NewYork City.

FROM THE STEAM PRESSES OF JOHN A. GRAY.

AMERICAN AGRICULTURIST,

FOR THE

Farm, Garden, and Household.

"AGRICULTURE IS THE MOST HEALTHFUL, MOST USEFUL, AND MOST NOBLE EMPLOYMENT OF MAN."—WASHINGTON.

ORANGE JUDD, A.M., EDITOR AND PROPRIETOR.
Office, 41 Park Row, (Times Buildings.)

ESTABLISHED IN 1842.
Published both in English and German.

$1.00 PER ANNUM, IN ADVANCE.
SINGLE NUMBER, 10 CENTS.
For Contents, Terms, etc., see page 288.

VOLUME XXI—No. 9. NEW-YORK, SEPTEMBER, 1862. NEW SERIES—No. 188.

Entered according to act of Congress in the year 1862, by ORANGE JUDD, in the Clerk's Office of the District Court of the United States for the Southern District of New-York.

☞ Other Journals are invited to copy desirable articles freely, if each article be credited to *American Agriculturist.*

☞See the Last Page, this month.

September.

"Wouldst thou thy vats with generous juice should froth?
Respect thy orchards; think not that the trees
Spontaneous will produce an wholesome draught.
Let art correct thy breed; from parent bough
A cion meetly sever; after, force
A way into the crab stock's close-wrought grain
By wedges, and within the living wound
Enclose the foster twig; nor, over-nice,
Refuse with thy own hands around to spread
The binding clay; ere long their differing veins
Unite, and kindly nourishment convey
To the new pupil; now he shoots his arms
With quickest growth; now shake the teeming trunk,
Down rain the impurpled balls, ambrosial fruit."
PHILLIPS.

With all that is said and sung of new fruits, and new varieties, there is danger, perhaps, that the attention will be diverted from that oldest and most widely distributed fruit, the apple. While men are priding themselves upon their splendid pears and grapes, apples very naturally fall into the back ground. Pears take the lead in the discussions at the Pomological Societies and make the biggest show at the horticultural and agricultural fairs. Tap a fruit grower on pears or strawberries and he will run freely; on apples he soon dries up. He will hold you by the hour on the wonderful performances of his new seedlings from the Bartlett or the Diel, but has no enthusiasm for the apple. It is given over, in far too many instances, to farmers and unskilful cultivators.

Yet the apple is the fruit for the million, and is a greater source of wealth to the nation than any other fruit we cultivate. It came over with the first settlers from England, and we very soon find traces of it in the early records of the colonies. It is not a very old fruit, even in the fatherland. Leonard Mascal has the fame of first introducing the cultivated apple into England, about the year 1525, less than a hundred years before the settlements of Jamestown and Plymouth. It was highly prized by the colonists, and it was the ambition of every settler who owned a plantation, to have his orchard, and his cider-press. The liquor seems to have been prized, both here and in England, more highly than the fruit. The orchard suggested hogsheads of cider fermenting in the cellar, rather thau barrels of choice winter fruit for family stores, or waiting a market. This view of the uses of the orchard impressed itself upon the whole population, and cider became a common drink at the tables of rich and poor, until the dawn of the Temperance reformation some thirty years ago. The fact that apples were grown principally for the press, made cultivators careless of the varieties. An apple indifferent for eating made a fair liquor, and seedling were quite as likely to be planted as grafted trees. Indeed many of the old orchards of the second and third generations are still largely made up of seedlings. Notwithstanding the low aims of the cultivators, the apple flourished in our new soil and climate, beyond all that the colonists had ever seen in the old country. Many of the trees raised from seed bore first-rate fruit, and we are indebted to chance seedlings for some of our best varieties. Indeed by far the larger part of the best apples upon our lists are of American origin. The Newtown Pippin is generally admitted to be the finest apple in the world. In eating qualities the Baldwin, the Spitzenberg, the Northern Spy, King, Swaar, and Cogswell are not much behind it.

The high price of apples, running from two to five dollars a barrel for good winter fruit, is a clear indication that we have not orchards enough. We believe a consultation of the price list would show a pretty steady advance for the last thirty years, notwithstanding the thriving business done by our nurseries and the immense number of orchards planted. For this there are a variety of causes. The extensive disuse of cider as a beverage has had some influeuce. Some thought it wrong to grow a fruit so liable to be perverted. A few cut down their orchards as a nuisance. Many thought it useless to plant orchards when there was no louger to be a demand for cider. Apples were so pleuty and cheap in many parts of the country that the only way to turn them into money was to make cider of them. Good winter fruit could be had in any quantity for fifty cents a barrel, and at that price it would not pay for a long transportation. It was like the plethora of corn upon the prairies away from railroads, where they use it for fuel. Few thought it an object to plant orchards for the fruit aloue. Apples at three dollars a barrel in a year of plenty was a thing undreamed of. Most of the old orchards planted in the last century have ceased to be productive, and many arc entirely gone.

And while the orchards have been decaying, our population has been rapidly increasing, and concentrating more and more in cities and villages, where apples are not produced. The new lines of intercourse by rail and steamer between city and country have advanced the price of this fruit, and of all other farm products. All classes are educated to the use of this fruit, and it is felt to be almost a necessity of living. The demand, though not as large, is as steady as for corn or potatoes. Any favored region that produces a surplus of apples, in a year of scarcity, is immediately drained of its treasures at high prices. There are few years that do not see thousands of barrels sent from central and western New-York into New-England, and in years of scarcity apples from Ohio, Michigan, and farther west, find a good market in the east.

The demand is also increased by new facilities for drying the fruit. This is done not only in the household by old methods, but by a machine inveuted for the purpose. Immense quantities are used in this form by families, and for ship stores, in long sea voyages. It pays very well in places remote from railroads when the fruit is plenty, to send it to market dried.

Besides these influences working at home, there is an ever-increasing demand for American apples abroad. The same varieties are fairer and finer flavored upon our side of the water, and several of our American apples have no rivals in the European market. Newtown Pippins are sold in the London market sometimes as high as nine dollars a barrel. This demand is likely to increase in coming years, even beyond our ability to supply it, as steam communication multiplies. Large quantities of apples also find their way to the West Indies, and to other tropical climates, in exchange for their fruits—oranges, lemons, pine-apples, and bananas. These fruits in our cities, brought by steam, are a fair indication of the abundance of ours in their seaports. This exchange of the fruits of different climates is one of the beautiful things of commerce. Pineapples and bananas were unknown to multitudes before the advent of sea-going steamers. They are now hawked about the streets of our seaports in hand-carts and wagons, about as plenty and cheap as apples, and find their way to our remotest villages.

These considerations should disabuse our minds of the notion not unfrequently cherished, that it will not pay to plant an apple orchard. The market is in no great danger of becoming glutted. This has never been, and is still less likely to be, in future years. The uses of this fruit will increase at home, and both in the dry and fresh state, will enter still more largely into our commerce. We doubt now if any part of the farm pays as well as the thrifty, well cultivated orchard. It can not fail to pay still better in the future. Our hearts warm at the sight of this ruddy fruit, hanging from the loaded trees, and at the memories that cluster around it, in our younger years—apple parings and other scenes of social festivity by the farmer's fireside.

Calendar of Operations for Sept., 1862.

[A glance over notes like the following will generally call to mind some piece of work that would otherwise be forgotten or neglected. The remarks are more especially adapted to places between 38° 40′ and 40° 45′, but will be equally applicable further North and South, by allowing for latitude.]

Farm.

The second step toward the supply of the great staple crop—wheat—for 1863 is now to be taken, and it is of momentous importance that it be *well* taken. The first step of preparing the ground is, or ought to be, now completed, and the profits of next year's crop depend on its having been well done. One important thing may yet be done in addition to seeding, namely: top-dressing with lime, salt, plaster, well-rotted stable manure, guano, marl, muck, or whatever the nature of the soil most requires, which, well harrowed in just previous to or at the time of seeding, often proves a paying investment. The important work of underdraining heavy soils may be advantageously attended to this month. Gathering fruit, and other maturing products, is another important matter to be considered, in laying out farm work for the month. A good crop must be well taken care of, to bring full returns. All kinds of stock should be kept in good flesh. The regaining of lost flesh is always expensive.

Agricultural Fairs and Cattle Shows—Every man gains something by attendance at these gatherings, aside from the recreation and social enjoyment. No one can tell what he loses by staying away. It may be worth $100 to any man—one spends a dollar, goes and gets the benefit; another earns a dollar by staying at home—which is the best off? (See article on page 265.)

Barns—Need frequent inspection to see that they are well ventilated, free of vermin and stench, tight-roofed, well preserved with paint, and not liable to be fired through carelessness. A good lightning rod upon a building may save it and its contents.

Beans—Well cleaned and good beans always bring a high price in market; if cured without mussing, the haulm and immature beans are excellent sheep fodder.

Beeves—Select for fattening; feed some old corn if you have it. Keep them quiet whether stalled or in pasture.

Buckwheat—Shells badly if allowed to become too ripe before harvesting. (See page 305, July *Agriculturist*.)

Buildings—Erecting new and repairing old should not be delayed until cold weather.

Butter—This month and next put down for winter use, and for market. But it is about as well to throw it away as to pack it so that it will not keep. The amount that is annually lost to the country in spoiled butter is immense—all the result of ignorance or carelessness. (See p. 278.)

Cabbages—Give good cultivation; frequent stirring of the soil keeps them growing and makes them head well.

Cattle—Give them clean, cool places for rest and sleep, plenty of clean water, and if the pastures are short, cut corn fodder, or suckers from the field; give them inferior cabbage plants, pea straw, etc.; pull roots when they are crowded, and at any rate keep cattle well fed; the profits of the year depend upon it.

Cellars—Have a good one under the barn as well as the house, so that vegetables from which effluvia is liable to rise may be stored there, thus obviating the possibility of bringing disease into the household. See that causes of offensive odors are promptly removed from the cellars.

Cisterns—Every house should be provided with a good one, and it should be thoroughly cleaned out, and repaired, if needing repairs, between now and the season of Fall rains. Should it happen to be dry, be sure to clean it.

Corn—Will soon be ripening. Select the earliest large ears on prolific stalks for next year's seed. Topping, or cutting off the stalks above the ears, is not so good a method as cutting the stalks close to the ground, and setting into stooks. See Prize Article in April No., page 110. There is a saving in fodder, in the manure heap, to the land, and of labor.

Draining—Standing water is hurtful to almost every farm, orchard, and garden crop. It is better to get rid of it by surface ditching, than to let it evaporate or soak away. In many instances low places may be drained by digging or boring (with a post auger) down through the clay stratum into a looser one that will permit the water to soak rapidly away. While the low places are dry, or comparatively so, is a favorable time to bore or dig down. In many places it will be easier to dig a large hole for a well several feet deep, than to conduct the water off either with tile or ditches. Those who have dug wells upon their farms can form an idea as to the probable distance down to a loose sand or gravel stratum.

Eggs—Generally bring a good price in Winter, yet it is well to sell when fresh, if the price is remunerative. The shell of the egg is porous, and unless encased in a way that will exclude the air, it will not keep well. Packing in salt is a very good way, and also dipping in melted tallow and packing in chaff is highly recommended. The tallow closes up the pores, and the chaff lessens the danger of breaking.

Fences—Let timber for posts, etc. Rotted posts should be replaced before the high winds of Autumn tend to break them off, and sound ones with them. And in the Spring one's time will be more valuable than at certain seasons this Fall. Where fences are indispensable, let them be good ones. Clear others away.

Flax—Should be pulled as soon as the straw becomes yellow, and the seed, within the capsule, has assumed a pale brown color. (See page 107, April *Agriculturist*.)

Grain—Thrash as fast as practicable, and market as soon as fair prices prevail. The degree of risk in keeping depends on the conveniences for storing. Grain in a good vermin-proof bin is perhaps better than money in an uncertain bank, or at hand where it is liable to be frittered away for things not really necessary. Good judgment in this matter is quite as important as in growing.

Harvesting—Is a very important branch of farming. Good crops of any kind poorly harvested, are often less profitable than poor crops well harvested.

Manure—The farmer's "reserve force." Let it be promptly and continually "re-inforced." The dryness of the swamps usually renders getting out muck for composting easier now than at most other seasons of the year. Besides, the roads are good. The poultry and hog droppings, neglected during haying and harvest, should be gathered and composted. The present is of all others the most propitious time for gathering all sorts of vegetation for increasing the compost heap.

Plowing—Is always in order where land is idle and weeds are getting a start. It is far better to thus convert them into fertilizers than to let them become seed-bearers. The plow that runs deep enough to turn up a thin layer of new subsoil, adds new stores to the farm, which will be filled without additional labor.

Potatoes—Leave in the ground those where any appearance of the rot is in the field, and dig very late, after all have rotted that will. It will be well to try pulling and burning affected haulm, at least from the patch infected first. Plow this patch as soon as the potatoes are harvested, to convert weeds and haulm into manure, and leave the ground in better condition for next year.

Poultry—Should have free range among the grasshoppers, worms, etc., at least a few hours before sunset. (See article on page 268.)

Root Crops—Need frequent stirring of the soil around them during this baking season.

Rye—Should be sown at the same time and in the same manner as Winter wheat, but preferably a little later.

Sheep—Will need a little extra care now to keep them in good wintering condition.

Soiling Crops—Cut freely and feed wilted, if there is any lack of pasturage. Corn fodder should be cut and cured before danger from frost.

Sorghum—Cut as soon as the seed has ripened, and hurry its manufacture before a frost injures it. If exposed to frost grind up immediately, before having time to sour. Cut off the extreme tops for seed or fodder, before grinding. If for sugar, reject from a third to one half of the upper portion of the stalks.

Swine—Keep them from running too freely, supply them with clean bedding, and commence to fatten early. Those for your own use, at least, should not be *excessively* fat before killing. Some farmers wash off their hogs as often as once a week; the pork is better for it, and so is the health of the hog.

Timothy—Sow with Winter grain for meadow.

Turnips—Thin out late sown, and stir the soil amongst earlier ones.

Weeds—Expunge, extirpate, exterminate! make ashes of those that have gone to seed, compost of the rest.

Wheat—Get seed in early. Experience abundantly proves that it pays to drill it in, requiring less seed, placing it all at a depth where it is little liable to injury by frost, out of the reach of pigeons and poultry, securing a greater uniformity of growth and of ripening, and, by giving better access of air to its stalk, roots, and the soil, lessening the liability to rust, smut, etc. Pickle the seed to prevent smut. See prize articles in July *Agriculturist*.

Orchard and Nursery.

The earliest apples and pears have already been gathered, but others are daily ripening, and must be harvested, or they are lost. The abundant yield requires considerable labor to properly secure them. Where accessible to market, they should be hand-picked, or taken off with one of the various fruit pickers described in the *Agriculturist*, and sold as fast as gathered. If at a distance from market, or where prices are very low, bottle, make into cider, or dry them for Winter use. Of course late sorts should remain upon the trees until October.

Peach growers are once more rejoiced to see their trees bending beneath the burdens of well-ripened fruit, and their faith in peach-culture is again revived. After marketing and using freely, there will still be a good supply to bottle, can, or jug, for the coming Winter. Rest assured they will be a luxury then, even if they are a drug now, and in the abundance of the crop, do not forget to provide for future years, by saving pits from the most healthy trees. Bury or plant them before they dry.

Marketing fruit of all kinds, and especially the soft fruits, requires a great deal of care. If one is aiming to become known in market as a first class, reliable grower, whose fruit shall always be in demand, the first thing is to provide substantial baskets or boxes of uniform size, plainly marked, and do not face or top the packages with the finest fruit, thus laying yourself liable to the imputation of dishonesty by wishing to deceive. Remember, that reputation is to be secured; and if from no higher motive, let the packages prove true to indications, that they may find a ready market as truthful to appearance, and honest in quantity. Many a basket of fruit is discarded in market when it is found, upon pouring it out, that inferior, and even poor fruit is at the bottom. Pears should almost always be picked and sent to market before they are ripe, and peaches *always* while a little hard. They may either remain and soften on the dealer's hands, or be disposed of to retail purchasers while they are still firm. Of course the fruit must be handled with the greatest care to avoid bruising. Some of the largest and finest specimens may be selected to make up a few baskets or boxes which will command extra prices, and this will scarcely affect the sale of the others, as the more uniform the fruit, the better it sells.

Early provision should be made for a stock of manure to top-dress the orchard and nursery. A compost of muck and stable manure, with a sprinkling of ashes, will form a good dressing.

Nursery trees budded this season should be examined, and the bandage "slit" or loosened where it is cutting into the stock. Every thing about the commercial nursery grounds should be put in readiness for beginning the Fall business next month. Young trees should be well tended, plowing between the rows frequently to loosen the soil and keep down weeds. Unless sufficiently trimmed, give them their last pruning early this month, to preserve low branching trunks. Omit the pinching now, as it would tend to induce a new growth, which would not ripen before Winter.

Kitchen and Fruit Garden.

Gathering and marketing or storing, are the chief labors of the Kitchen Garden at this season, and no small amount of judgment, as well as energy, is required to do these in a manner that will enable one to reap maximum profits. Either ignorance or carelessness in gathering, marketing or storing garden products may prove as great disaster as they are liable to in cultivation. A potato bin or hole insufficiently protected from frost, or stored with decayed or decaying tubers intermixed, melons plucked before ripe; cucumbers packed in musty or leaky casks; seeds put away where dampness or mice will destroy them; pumpkins, etc., left within tempting sight of fence-breaking or trespassing cattle and swine; fruits bruised by reckless handling, etc.—these are only a few of the ways in which the previous labors of the season may be largely sacrificed, to say nothing of taking produce to market in such a shiftless state of preparation as to bring but second to fourth-rate prices. See to it, therefore, that these things are well and seasonably done. Wherever draining or trenching will be of advantage to the garden, push it forward whenever other work will permit. Strive to produce specimens of vegetables and fruits worthy of exhibition at your County Fair. It may enable you to sell seeds, plants, etc., at good prices.

Beans—Gather and put in a dry place as fast as they ripen. Before marketing, clean thoroughly. Unripe Limas dried are excellent for Winter use.

Blackberries—Remove the old canes and weak shoots, leaving one or two of the strongest for fruiting next season.

Cabbage and Cauliflowers—Keep late plants well hoed, and sow seed for plants for cold frames.

Celery—Earth up as often as once in two weeks with dry soil, taking care that no dirt be left on the crown or between the stalks. Tie with soft string or bass matting.

Corn—Save the earliest large ears on prolific stalks for next year's seed. Shave green corn from cob and dry. Cows will relish the stalks green or cured.

Cucumbers—Keep well watered; let early specimens ripen for seed. For sour pickles use small green ones; for sweet pickles, those nearly ripe are recommended.

Endives—Hoe and give liquid manure, treating like lettuce; gather and tie up the leaves for blanching.

Grapes—Leave until fully ripe before gathering, unless there is danger from frost. (See suggestions for packing for transportation on page 245, August *Agriculturist*, and for wine making on p. 277, this number.)

Hoe where weeds grow, or the soil needs stirring.

Hops—Gather and dry, and preserve poles for future use.

Manures—Let no source be overlooked. You want their help for next year's crop.

Melons—Place pieces of boards under those ripening, and turn the melons over occasionally. Gather when fully ripe and use or market. The sound from tapping on or snapping the melon with the finger nail is a good criterion to judge of the ripeness of a melon, the ripe melons giving forth a dull, dead sound, while that of an unripe one has more or less of ring to it.

Mushrooms—Beds may still be made. (See directions on page 213, July *Agriculturist*.)

Onions—Sow for sets to use for rare pies next Spring.

Parsley—Sow for use next Spring.

Pickles—See directions, pp. 246 and 279, *Agriculturist*.

Raspberries—Treat as directed for blackberries. House stakes for future use.

Spinach—Sow in drills 14 inches apart for next Spring.

Squashes—Pack Winter squashes away in a dry place, as soon as ripe, or before danger from frost.

Strawberries—Finish transplanting, and water when needed or mulch. Keep well loose, if not mulched.

Tomatoes—Make pickles, or catsup, or preserve in air-tight jars or bottles. See directions p. 279.

Turnips—Thin out, if needed, and keep well hoed. Bone-dust hoed in is a good manure.

Winter Cherries may be kept for winter use by packing in cotton with the hulls on, or they may be preserved.

Flower Garden and Lawn.

If properly attended to in the Spring, the flower garden is still "a thing of beauty." Many of the annuals and bedding plants are yet in bloom, and the later perennials, conspicuous among which is the dahlia, are out in all their splendor. The mistake of not planting a good supply of annuals and late perennials is too frequently made, which occasions a dearth of bloom in September and October. Now is the time to save seeds for another season. Select from marked stalks, which have ripened their seed, and which were designated on account of fine form and color, or a more double flower. Having gathered the seed, cut away the flower stalks of these and other plants out of bloom and not intended for seed.

Bulbs should be planted the last of September, if practicable. See full directions on a subsequent page.

Chrysanthemums will soon begin to flower. Keep well tied up, and cut out the weak shoots, leaving but few stalks in a place.

Cuttings for propagating plants should be made as soon as the wood is mature. Insert in a light, deep soil, with plenty of peat and sand worked in, and cover with a hot-bed sash, shading from the hot sun. They will soon root, and may be potted for Winter.

Dahlias ought to show finely now. Keep well tied up or the rains and winds will split them down. Mark them while in flower, giving the correct name where it is known, otherwise the color and form of the flower, and habit of growth. Remove decayed flowers as soon as they become unsightly.

Lawn—Keep free from leaves, and scatter a little seed on bare spots. Sow Winter rye, on ground prepared for a lawn, but which is not to be seeded until Spring. A thick growth of rye will look very well during Winter.

Seeds—Watch their ripening and collect before they are wasted on the ground. Mark each package with care. Mark with strings the finest late blooms, the seed of which it is desirable to save.

Verbenas and Petunias layered last month, may now be divided and potted for Winter blooming.

Weeds—Allow none to disfigure the ground or to sow seeds for a future crop. Burn those bearing matured seeds.

Green and Hot-Houses.

One of the first things to be done is to see that the houses are prepared to receive their Winter stock. If new ones are to be built, let them be put up at once. Before the close of the month, many of the more tender plants will need bringing in. They should never be left out until chilled by cool weather. See that pots are clean and plants properly cut back, and decayed leaves removed when set in Winter quarters. The houses should have abundance of air and sunlight for some time after being filled, or the change will affect the plants unfavorably. Collect a good stock of old turf, well rotted peat, sand, and manure for potting soil. Mix it early, for it improves by age. Lay in a supply of pots of various sizes to be in readiness for shifting the plants.

Having cleansed and painted the houses, attended to the glazing, arranged the furnaces, and brought in the tender plants, setting them tastefully in their appropriate places, begin at once to increase the stock by putting in cuttings of the several varieties needed. Sow a few desirable annuals at the same time to increase the number of Winter plants. The Cape and other house bulbs should now be potted and arranged for growing. Some of the hardy Spring blooming sorts may also be potted, and set in a cool place to be brought forward as wanted.

Camellias should be re-potted. They are now beginning to grow and require frequent waterings. It is not too late to bud and inarch.

Fire heat may occasionally be needed in some apartments to expel dampness and warm the air.

Grapes—The treatment must be governed by the different stages of growth. Give little water and abundance of air to those ripening, and frequent syringings to later sorts.

Potting—Most of the plants will need re-potting when brought in, although they have been growing in pots during the Summer. They will do better with a change of soil, and quite likely they require more room. All of the large number of house plants set in the borders in the Spring, are to be potted now. They should be shaded, after the operation, and watered freely. Many of the plants will be benefited by cutting back.

Apiary in September.

Prepared by M. Quinby—by request.

Should you hear a bee-keeper complaining that his hives were robbed by neighboring bees, and you should tell him that it was his own fault—neglect of some duty—you would be right nine times in ten. Although attention has been frequently called to this one point, but few seem to heed it. There is a general failure of honey-yielding flowers this month; some of the combs will be occupied with brood as long as honey is obtained; this brood hatches now, and of course there must be empty cells. The bees of a large colony are always restless, and on the lookout for honey while there are any cells unfilled. Any colony too weak to defend its stores, is liable—yes, almost certain—to be found, and its stores taken by force. This gives rise to vexations at home, and contentions with neighbors. A little care now is all that is needed. Examine each colony, and remove all that have not bees sufficient to defend their stores. Stock affected with foul brood will often appear stronger than they really are; they gain nothing by standing longer, and the consequences, if robbed by others, are serious. Remove them now. Any other condemned colonies, if strong enough to defend themselves, may be left until next month for the bees to all hatch out of the way. A queenless stock with sufficient honey, may be supplied with bees and queen from condemned colonies. If bees from a hive with foul brood are taken, they should be driven into an empty hive for a day or two, to use up the honey taken with them; otherwise they might with it infect the hive where they go. The honey in the diseased hives may be strained, after removing all the pupæ mixed with the brood. By purifying it, it will do to feed some light colonies next month. Next month will do to feed and unite light ones, but take care of the badly diseased and very light ones *now*.

Exhibition Tables at the Office of the American Agriculturist.

The following articles have been placed on our tables since the report for last month:

Fruits, etc.—*Currants*—La Versailles (extra fine), Cherry, White Grape, Imperial Jaune, Victoria, Imperial Red, La Fertile and Champaigne, from A. S. Fuller, Brooklyn, L. I.....Branches with Red and White Currants (very fine, and loaded with fruit,) and Fontainbleau, from Geo. H. Hite, Morrisania, N. Y.....Prince Albert currants from W. S. Carpenter, Rye, N. Y.....Cherry, Victoria, Prince Albert, variety for name, White and Red Grape, Red and White Dutch, Short-bunched Red, Black Naples, Champaigne, La Versailles, Gloire de Sabion, (very fine and most tastefully arranged for exhibition,) from E. Williams, West Bloomfield, N. J.....La Versailles Currants (extra fine), from D. J. Woolsey, Milton, N. Y.....Red Dutch Currants (fine), from Dr. I. M. Ward, Newark, N. J.....*Gooseberries*—Samples from J. G. Odell, Marshland, Staten Island.....Lancashire Lad, Whitesmith, Golden Drop, Lincolnshire Green, Pride of England, Washington, Crown Bob, Little Warrington, Ironmongers, from James Hunt, Flatbush, L. I.....American Seedling, Whitesmith, from E. Williams, West Bloomfield, N. J.....Crown Bob (fine), from J. P. Major, Williamsburgh, L. I.....Houghton's Seedling (spiral training), Geo. H. Hite, Morrisania, N. Y.....*Strawberries*—Russell's Prolific, from Geo. Clapp, Auburn, N. Y.....Great Austin, Wizard of the North, La Constante, Deptford Wife, Downer's Prolific, Seedling Eliza (all gathered July 16), from W. S. Carpenter, Rye, N. Y.....*Raspberries*—Belle de Fontenay, from W. S. Carpenter, Rye, N. Y.....Doolittle's Improved Black Cap, from L. A. Lawton, Hauppauge, L. I.....Improved Black Cap, Improved White Cap, Hudson River Antwerp, Ohio Everbearing, Belle de Fontenay, Brinckle's Orange, from E. Williams, West Bloomfield, N. J.....Clarke Raspberry, (extraordinary growth and vigor), from E. B. Clarke, New-Haven, Conn.....Monthly Raspberry, (white and fine-flavored,) from W. S. Carpenter, Rye, N. Y.....*Blackberries*—Dorchester, from E. Williams, West Bloomfield, N. J.....Green Blackberries, (remarkably curious) from Dr. Clowes, N. Y.....Red Blackberries, (fine and very fine-flavored,) from M. L. Force, Morristown, N. J.....New-Rochelle, from C. A. Cadman, Thompson's Station, L. I.....New-Rochelle, from A. C. Chamberlain, Novelty Gardens, Brooklyn, L. I.....New-Rochelle (very fine), from Chas. Rivinius, Morrisania, N. Y.....New Rochelle and Dorchester, from E. Williams, West Bloomfield, N. J.....Cultivated Wild Plums, called Egyptian Cherries (very fine), from Robert Jarvis, Newtown, L. I.....Apricots from P. I. Buchanan, 54th street, N. Y.....Very large and full branch of Apricots from A. C. Chamberlain, Novelty Gardens, Brooklyn, L. I.....*Apples*—Samples for name, from J. A. Brush, Brooklyn, N. Y.....Dutchess of Oldenburg, etc., from E. Williams, West Bloomfield, N. J.....Red Astrachan, Summer Queen, variety for name, Primate, from Dr. I. M. Ward, Newark, N. J.....River Streak, Julian, Early Harvest, Sine-qua-non, Early Catherine, Red Astrachan, Manomet, Benoni, Cloth of Gold, Early Red Margaret, Summer Hagloe, Sweet Bough, Summer Queen, Summer Pippin, Primate, Early Strawberry, Summer Rose, Gravenstein, Hawley, from Wm. S. Carpenter, Rye, N. Y.....*Pears*—Madeleine (branch extraordinarily full—tree planted eight years, yields a barrel of fruit this season), Rostiezer, Jargonelle, Dearborn Seedling, Rousselet Stuttgart, Doyenne d'Etc, Bloodgood, Beurre Giffard, Osband's Summer, from Wm. S. Carpenter, Rye, N. Y.....Early Windsor or Summer Belle (very full branch), from E. Williams, West Bloomfield, N. J.....New-Haven Seedling, from E. E. Clarke, New-Haven, Conn.....Vale, from Dr. Ell Ives, New-Haven, Conn.....Seedlings, from L. C. Lighthipe, Orange, N. J.....Roetzer, Bloodgood, Dearborn Seedling, from Dr. I. M. Ward, Newark, N. J.....Cuban and Fejee Island Tomatoes, from G. M. Usher, Port Richmond, Staten Island.

Flowers, etc.—Yucca gloriosa, Passiflora Decaine, Dahlias, Hollyhocks and cut flowers, from Mr. Cunningham, N. Y.....Cut flowers in variety, Carnations, Larkspurs, Gladiolus (100 varieties, very fine), from A. S. Fuller, Brooklyn, L. I.....Double Hollyhocks, (from imported prize seed—very beautiful), from Wm. S. Carpenter, Rye, N. Y.....Roses, Dahlias, Carnations, Double Zinnias, Phloxes, Coboea Scandens, etc., (very fine) from C. S. Pell, N. Y. Orphan Asylum.....Wild Prairie flowers, from A. Hitcheock, Farmers' Grove, Minn.....Cut flowers in variety, Dahlias, from Mrs. O. Judd, Flushing, L. I.....Seedling Phloxes, Cut flowers, Asters, Marigolds, Portulaccas, etc., from W. F. Heins, Woodstock, N. Y.....Baptisia tinctoria, or Wild Indigo, from Long Island.....Tiger Lily (extraordinary growth, 5 ft. 5 in. from ground to top of stalk), from Thos. B. Kinsman, Jersey City, N. J.....Double Zinnias, Dahlias, Cut flowers in variety, from E. Williams, West Bloomfield, N. J.....Achimines Burgmanii, A. grandifolia, from Thomas Kearns, gardener to Wm. Shaw Esq., Staten Island.....Cut flowers, Larkspurs, Lilies, Phloxes, Hardy Plumbago, Mahonia aquifolium, Mahonia Berry, Berberis Vulgaris, Barberry, Berberis Canadensis, American Barberry, from A. C. Chamberlain, Novelty Gardens, Brooklyn, L. I.....Caper Spurge, Euphorbia Lathyris, Introduced from Europe.....Coreopsis tinctoria, from Mr. Hayward, Brooklyn, L. I.....Asters, Fuchsias, Sugar Cane, Black Warrior Phlox, Centaurea, (in pots) from O. Judd, Flushing, L. I.....Stipa pennata, (a very fine feathery grass,) from John G. Waite, Englewood, N. J.

Vegetables, Seeds, etc.—Oats (5 ft. 10 in. high), from E. G. Faile, West Farms, N. Y.....California Mercer Potatoes, (very early) from W. F. Heins, Woodstock, N. Y.....Three stalks of Marrowfat Peas—10 ft. to 10 ft. 7 in. high—(very tall indeed,) from A. S. Nash, Westport, Conn., per Dr. Bouton, Center-st., N. Y.....Egyptian or Minnesota White Spring Wheat, from J. L. Armstrong, Lake City, Minn.....Cucumber (fine, over 3 lbs. weight,) from A. L. Winship, Flatbush, L. I.....Egg gourds (curious), from J. B. Bryant, Brooklyn, L. I.....Specimen of Heather (Heath Grass) from Sheep land of Jonathan Peel, Knowlmere Manor, Clitheroe, Yorkshire, England, by O. Judd.

Miscellaneous.—Belemnites, (fossil cuttle-fish bones) from the green-sand marl formation at Holmdel, N. J., by J. C. Taylor.....Sorgho Sugar (very good—made on Cook's Evaporator,) from Blymyers, Bates & Dav, Mansfield, Ohio.....Rocky Mountain Goat horns (very large),

from W. A. King, N. Y.....Wool from the side of a *Black-faced Sheep*, (which took the first prize at the Royal Agricultural Society's Show, England), viz.: a Ram called "Ayrshire Laddie," 1 yr. and 2 mos. old, bred by Capt. Kennedy, of Glenapp, Ballantrae, Ayr, Scotland, and exhibited by Jas. Drife, of Barr, Sanquhar, Dumfries, Scotland, by O. Judd.....Wool from a pure bred Leak ram, 4 yrs. 3 mos. 1 week old, called "Son of the Mountain King," bred by Jas. Duerden, Marsden, Colne, Lancashire, England, exhibited by Jonathan Peel, Knowlmere Manor, Clitheroe, Yorkshire, England, by O. Judd Wool from Black-faced Sheep, Ram "Donald," 2 yrs. and 2 mos. old, bred by David Toyer, Knowehead, Campsie, Sterling, England, exhibited by Jas. Drife, of Barr, Sanquhar, Dumfries, Scotland, by O. Judd.....Wool from Black faced Sheep, Ram "Bob," 2nd prize, 1 yr. and 2 mos. old, bred by David Toyer, Knowehead, Campsie, Sterling, England, exhibited by James Drife, Barr, Sanquhar, Dumfries, Scotland, by O. Judd.....Wool from *French Merino Ram*, 3 yrs. 6 mos. and 10 days old, bred and exhibited by Chas. Lefebore of St. Escobille, Seine and Oise County, France.....Wool from a pure Leak breed ram, "Mountain King," 7¾ yrs. old, bred by W. Windup, Hould Top, Silsden, Yorkshire, and exhibited by Jonathan Peel, Knowlmere Manor, Clitheroe, Yorkshire, England—the above brought by O. Judd from Royal Agricultural Society's Exhibition, held in London, England, June 23d, 1862.

Agricultural Exhibitions for 1862.

STATE AND 'NATIONAL' FAIRS.

Name.	*Where held.*	*Date.*
National Wine Fair, (U. S.)	Washington, D. C.	Jan. 14 to 63
National Horse Fair	Williamsport, Pa.	Sept. 2– 5

NEW-BRUNSWICK.

Kings Co. Central	Hampton Ferry	Oct.	8—

The Address at the N. Y. State Fair,

is to be delivered by Robt. J. Breckenridge, D.D., LL.D., of Ky., whose devotion to the cause of the Union, involving the sundering of friendship and paternal, and other strong family ties, has enshrined him in the hearts of the American people. Dr. B. is well known as an enthusiastic Agriculturist, and his address will doubtless be appropriate and valuable.

Number of Pounds in a Bushel

IN THE DIFFERENT STATES.

The following table is published to answer the inquiries of several subscribers. It is as complete as we have means at hand to make it. We shall esteem it a favor to have any additions or corrections made to it, and will republish the table if we receive such. The letter m, signifies sold by measure.

Containing a great variety of Items, including many good Hints and Suggestions which we give in small type and condensed form for want of space elsewhere.

SPECIAL ATTENTION, is invited to the business notices in this paper. Sundry General Premiums are offered on pages 281-2. Also some extra premiums of value at this time, page 288. Please note *Strawberry Premiums*, Maps, etc. The offer of the remaining numbers of this year *free* will be a special stimulus to new subscribers, and assist in making up premium clubs. Mr. Judd will be home in season to take the general oversight of the next issue of this journal, and after his respite, he will doubtless be able to add much to the spirit and interest of the future numbers.

Note to Crop Reporters.—We earnestly invite all to fill out the September blanks, and with special care as the final reports for the year. These reports are the most reliable, and by far the most systematic and complete published in the world. They are looked to by dealers, by the general press of this country and abroad. They are of most use, however, to farmers themselves, as indicating the general yield of the different crops, and the probable prices. The September reports vary somewhat from the previous month, in giving the results of the haying and harvesting. Please send them in promptly on or before the 10th. We can not wait for those arriving after the 15th.

Mr. Taylor's Sale and Letting of Sheep, on September 3d, should not be forgotten amid the excitement of the draft and other war matters. The occasion will be one of interest both to those desiring to purchase or rent South Down Sheep, and to farmers generally. In England, such sales and lotteries attract hundreds and even thousands of persons from all parts of th kingdom and from other countries. We hope to meet a large delegation of our readers on the steamboat which leaves the foot of Robinson-street at 9 A. M., on the day of sale. For particulars see advertisement on page 255, August *Agriculturist*.

A Convention of Wool Growers of Vermont will be held on the fair ground at Rutland, Sept. 9th. All interested in the production of wool are invited.

American Pomological Society.—The Biennial meeting commencing Sept. 17, at Boston, will doubtless be attended by every grower and lover of fruit, who can possibly be present. This society has done much to improve the growth and quality of our fruit, and is worthy of general co-operation.

Employments for Women.—Mr. Judd, writing from Germany, says: "....I have noticed here, and indeed all through England, France, and Switzerland, that women fill very many stations occupied by men in our country, such for example, as clerks in all kinds of retail establishments, and in railway stations, etc., etc. I may say that the employment of women as clerks in shops, is the rule, the employment of men the exception. The war, at best, will disturb the natural equalization of sexes; the European practice should and must come into vogue in our country, and at no time could the 'reform' be better inaugurated than now, when a million or more men are away in the army.....It will be well to invite suggestions on this subject for the columns of the *Agriculturist*. Let our journal, devoted as it is, part, to the Household, do its share toward promoting the change."

Clubbing to Equalize the Draft.—If of five men subject to draft, only one is taken by lot, the other four *ought* to share with him in some way. The following agreement, signed by about twenty of our colt, qualntances, seems to be the right thing, and we present it to the readers of the *Agriculturist* as worthy of imitation:

"We, the undersigned, do mutually covenant and agree that, in case one or more of us be drafted to do military duty in the war now waging, and the person or persons so drafted shall procure a substitute, we, the undersigned, will share equally the cost of such a substitute. And we further agree, in case the person or persons so drafted choose to go and do said military duty, we, the undersigned, will pay to him or his order, the amount of cost for such a substitute, dividing the cost equally between us. And we hereby appoint [the names of three persons are here inserted] as Executive Committee, whose duty it shall be to decide what price shall be paid the substitute or persons consenting to serve in the war; to collect and disburse, and make assessments, and decide all questions that may arise in executing the provisions of this agreement. This covenant made and signed this 11th day of August, 1862. As witness our hands."

Cultivating Wheat.—John Walting, of Clinton Co., Mich., writes that last Autumn he set aside a small portion of a wheat field, and drilled in the seed in rows 8 inches apart, and hoed it in Spring, but that at harvest it yielded almost nothing, while the rest of the field gave a good crop. We can only account for the failure by supposing that the earth was disturbed or heaped up too much around the roots. It is worth while to make another trial, and only hoe enough to kill any weeds that may grow. Whether salt or lime, or both, may be useful on your soil, may be best determined by trial on a plot by the side of another without the application.

Variegated Plants.—"L. W. S.," Mc. You can procure them of any of the larger nurserymen and florists, here or in Boston. Flower seeds like the Drummond Phlox, Pansies, Mignonette, etc., require very close watching to save them.

Treatment of Potato Seeds.—W. C. Comstock, Fairfield Co., Conn. Either dry the potato balls, and rub the seed out, or mash and wash them. Keep in dry place, and sow as other seeds in the Spring, covering with half-inch fine soil. The yield will be potatoes of the size of marbles. It takes two or three years for them to attain size and character.

Fancifully Colored Fruit.—C. S. Rust. You will be able to fasten the paper in which the designs are cut, which you wish to have photographed (drawn by light) on the fruit, by using sheets large enough to envelop the apple or pear, and tying it securely about the stem, and also below the fruit. Let us know how you succeed.

A Cistern as an Ice-Vault.—"J. C. C," of N. Y., has a cistern 9 feet in diameter, and 9 feet to crown of arch, which he wishes to use as an ice-closet, and asks if it will hold ice enough to keep through the season, and how to proceed to secure the least waste. We think that amount of good clear ice would keep if in large and solid blocks, well packed, while at a low temperature, and surrounded with a lining of straw, or perhaps of clean saw-dust, 8 inches to a foot thick, a pipe being provided, through which to drain off or pump out the water from the melting ice. Such an ice-closet would doubtless furnish a cool place for keeping meats, fruits, and other perishable articles, in hot weather.

Wild Flowers of Wisconsin.—The preserved flowers received from A. Hitchcock, of Greene Co., Wis., are: (1) *Phlox bifida*; (2) *Polemonium reptans*, Greek-valerian; (3) *Castilleja coccinea*, painted cup, (red,) and the variety *lutea* (yellow); (4) *Lithospermum canescens*, Alkonet; (5) *Lonicera flava*, yellow honeysuckle; (6) *Phlox divaricata*. They are all pretty, and worthy of cultivation.

A Rare Peony that does not Flower.—Root-pruning might help it. If very vigorous, divide it, and make new plants. Work in lime or wood ashes.

Flowering Plants in Cellars.—"Delia." All you need to do is to keep them in a dormant state. For this purpose, give them no more water than is just necessary to keep them from drying up, and keep them from all heat, like that from a neighboring furnace. Examine them once a fortnight.

Hybrid Perpetual Roses for the Lawn.—"E. G." By your inquiry, you mean, we suppose, those which are of moderate growth, and are therefore better suited for a bed on the lawn, than the tall growers would be. We recommend Giant of Battles, Pius Ninth, Duc D'Aumale, Baron Haller, Dr. Arnal, Baron Provost, Compte de Paris, Jules Margottin, Wm. Jessie, Mad. Laffay, Mad. Rivers, Duchess of Sutherland.

Auricula.—"J. L.," Mich. This flower is common enough among florists and amateurs, but is not yet popularized in this country, though it deserves to be.

Trailing Plant for a Vase.—"D. S." The periwinkle, (often called *myrtle*, improperly,) will not answer well in your vase, exposed as that is to the sun, and where it will seldom get watered. Some persons use the verbena, petunia, lobelia gracilis, and even scarlet geraniums. But one of the simplest and prettiest things is the Moneywort, (*Lysimachia nummularia*,) which needs watering only once a week or ten days, and whose trailing habit is similar to that of the periwinkle. For a symmetrical, classic vase, standing on a terrace or parapet, no plant is so suitable as the Century-plant. If you have a large, handsome vase, set on an appropriate pedestal, the upper rim of the vase just level with the eye of the spectator, put no plant in it. It is designed for a piece of sculpture, and should not be degraded into a flower-pot.

Geraniums Bloom Year after Year.—Dr. J. V. Riggs, Schenectady Co., N. Y. The geranium is a perennial, and the same plant will bloom for many years; but in your latitude, and indeed in any latitude where subject to freezing, they require to be kept in a green-house, or in the cellar during winter. We have frequently kept them in the cellar, setting them in pots or boxes of earth, in autumn. Young plants, however, are most desirable, and these are easily propagated. The cuttings or trimmings, or small pieces of them, will take root and grow readily when stuck into the soil and kept gently watered, and shaded for a few days. Your fine varieties may thus be rapidly multiplied.

Dwarfing Pears, etc.—"Utah." The dwarfing is occasioned by the smaller capacity of the quince roots—or other stock used for this purpose—to afford nourishment. Pruning only keeps the head in the desired shape. Roots sometimes strike from the pear above the quince stock, increasing the size of the tree.

Soil for Cranberries.—"R." Cumberland, R. I. Soil of the nature of beach sand is best for cranberries. The soil you describe—muck, underlaid by putty-like clay—is not suitable. By removing the top sod and substituting beach sand, if the plot can be properly overflowed, you may perhaps secure tolerable success.

To Keep Chestnuts.—Chestnuts may be kept in an ice-house for an indefinite time as fresh as when first gathered.

Best Manure for Strawberries.—C. S. Rust, Oswego Co., N. Y. On some soils strawberries do pretty well without manure. Muck, leaves, old sods, etc., composted 6 months with barn-yard manure, are the best. Guano serves as a temporary stimulant, used on land previously manured, but its effects are not lasting. Wood ashes are excellent, added to the soil, especially if the land be heavy or damp.

Green Blackberries.—Not the green, unripe fruit, but deliciously sweet and delicately formed berries, of a pea-green color, very distinct from the "white" sort, are exhibited at the *Agriculturist* office by Dr. Clowes of this City, who found them growing wild in Westchester Co. In shape they are long and tapering, and of medium size.

Cultivate Blackberries.—Letters from "Young Farmer" of Pa., and "J. W." of Ohio, and one or two others, indicate that the spirit of the article on Blackberries (page 241) was not fully understood. The aim of our associate evidently was to enforce *more care* in the culture and training of the plants. The *Agriculturist* has continually, and still does, advise *every* family to have its plot of cultivated blackberries. The editor of this paper first brought into general notice the New-Rochelle variety, and has labored to extend its culture, though without a penny's interest in the sale of plants. Our own experience and observation is, that after strawberries, a plot of ground can not be turned to better account than to fit it well, plant it with improved blackberries, and cultivate and train them carefully. Thousands of families who have followed our advice, are just at this season luxuriating in an abundant supply of this pleasant and healthful fruit.

Putty for Bleeding Grape Vines.—"N. N. H.," Ill., names this as a remedy. Rub the putty against the grain of the wood, or bind on with a cloth.

Coal Ashes for Peach Trees.—"J. O. S.," of Northampton Co., Pa., affirms that sifted coal ashes spread around under his peach trees to the depth of 5 or 6 inches, and a wash of whale-oil soap applied to the trunks twice a year, have proved of great benefit.

The Dwarfs.—Barnum is not all humbug. Since cracking the famous Nutt, (the Commodore,) people have everywhere accused him of having revamped Tom Thumb. To silence such cavilers, Mr. Barnum has now brought Gen. Tom Thumb and Commodore Nutt both together in the Museum, where any doubter can see them side by side. The Commodore has our vote as the smallest and smartest little man. Gen. Thumb has latterly too much the air of a self-satisfied, corpulent Englishman, to suit our democratic notion.

Curled Leaf in the Peach Tree.—A. R. Ashton, Burlington Co., N. J. We have seen no satisfactory explanation, and put it down with the potato rot, entil further developments.

Worms in Plums.—Mrs. D. F. Newton, Alleghany Co., N. Y. The worms hatching in the crescent shaped scars on the plums are caused by the curculio, or

plum weevil, which deposits its eggs there. You will see frequent allusions to it in the former numbers of the *Agriculturist*, and it is fortunate that this is its first appearance in your locality.

The Peach Borer.—"H. S." Have you tried coal ashes spread on the soil over the roots? A surer remedy, however, is to first dig out the borers with penknife or wire, then fill the holes with powdered sulphur. Afterward, surround the trunk with tarred paper.

Whale oil Soap—What is it?—J. A. Arnold, Saginaw Co., Mich. This is a residuary product in the purification of the crude whale oil as it is brought in by the whalemen. It is a black, oily soap, often called "black-soap." If dissolved in hot water, the oil partly separates; it should therefore be soaked in cold water and then when dissolved, it carries the superfluous oil with it. It has a disagreeable odor, adheres better than other soap and is very cheap. Of course it must be obtained directly or indirectly from the whale oil depots. It is kept on sale by Eastern implement and seed dealers.

Coal Tar for Plants and Bugs.—"A. P.," Vt., tried it around cabbages, it killed them. A neighbor tried it around melons; it killed them. He put the pumpkin bugs into the tar; it did not kill them. Rather a dangerous weapon, safer at the muzzle than at the breech!

Ant Hills in Flower Beds.—"S. F. D," Peru. We should scatter them with salt. They do not relish soap suds and liquid manure.

Remedies for Striped Bugs.—"A. F.," Bakersfield, Vt. A box with a glass cover, or millinet cover—A powder of four parts plaster and one of Peruvian guano, put on with dredging box, immediately after every rain—Strong quassia water, put on with sprinkler—Dead clams, or any other offensive animal matter—A chicken coop close by—Toads—Thumb and fingers applied every morning when the dew is on—Frequent watering with liquid manure. We have faith in all these remedies, especially the last four.

Obtaining the Agriculturist under Difficulties.—A subscriber in Washington Co., Iowa, in sending his dollar for the *Agriculturist*, says, that to obtain the money, he went *two* miles into the timber, chopped a load of wood, and hauled it *ten* miles to market. We are gratified at finding the journal so highly appreciated. It ought to be a good paper when such sacrifices are made to obtain it; we *try* to make it so, and shall keep trying.

Squirrels Carnivorous.—A lady subscriber affirms that she saw the common striped squirrel or chipmunk carry off a chicken, and moreover killed one in the act. This fellow burrows in the earth, and it may be that his habits are different from the rest of the tribe. The fact is new to us.

Gophers.—Thomas Bickerton, of Douglass Co., Kansas, is much troubled with gophers, and suggests that the hydrogill, or some similar thing, be used to inject "some inflammable material, with plenty of sulphur" into their burrows. Suppose you subject your idea to a practical test, Mr. B., and publish the result. We have also a suggestion to make. From repeated trial it has been found that wheat prepared as follows, will poison rats, mice, crows, etc.; Dissolve one drachm corrosive sublimate in one pint alcohol, and add one tablespoonful of molasses. Pour this upon four quarts of wheat, and let it stand covered until the wheat has absorbed the decoction, then spread out and dry, when it is ready for use. Why may not gophers be poisoned by corn prepared in the same way?

Seed Wheat.—"A. S. P.," Edinburg, Ohio, has increased the weight of his wheat two pounds in the bushel by selecting the ripest part of the field for seed, and screening for the largest kernels. He approves of soaking in brine and rolling in plaster or quick lime.

Hallett's Pedigree Wheat.—There is no denying the fact that Mr. Hallett is producing extraordinary results in his experiments with wheat. We have seen with our own eyes some of these results, and can bear witness that the large engravings of wheat heads we published last year are even less in size than those we saw and measured the present year. Some complaints have been uttered respecting the money-making account to which Mr. H. is turning his experiments, but he is clearly entitled to good remuneration for the expense of his experiments. He has shown, and is continually strengthening the proof, that as with animals, so with grains, improvements in the yield, and in the size and production of the heads and kernel, can be made to an indefinite degree by selecting extraordinary specimens for propagation. Thus, if one desires to secure short straw, long, well filled heads, etc., he has only to select and propagate each year individual plants strongly marked with the peculiar features it is desired to develop. The kernels from a large head this year will produce one or more larger heads next year. The largest one of the second crop will produce one or more still larger heads the next year, if the soil be very good; and so the improvement may be carried on indefinitely. We advise our more enterprising readers to experiment in this direction, not only with wheat, but with oats, rye, and other grains. A few years will develop an extraordinary product, which may be multiplied at pleasure. In this way may be secured greatly improved seed—to the benefit of the country, and to the pecuniary profit of the patient experimenter.

Indian Hemp Bark for Bands.—A subscriber of the *Agriculturist* who has tried it, recommends this material for tying up tomatoes, etc., to trellises.

Orchard Grass.—"A. K. McC," Chambersburg, Penn. This is a superior pasture grass, especially when mixed with red clover. It should not be sown alone—for it does not make an even sward—except for seed, in which case about two bushels are required to the acre. When sown with clover, one bushel per acre is sufficient, and in either case is best sown early in September. The clover should be sown in March following.

Wintering Cabbage Plants.—"D. C. Johnson." To get extra early cabbages in the Spring, prepare the ground the previous October, choosing a dry, warm spot; set out the plants a foot apart in drills, and get them well established by November. When hard frosts begin, put on a layer of straw or other porous litter across the drills, so as to keep off the winter sun, and to prevent constant freezing and thawing. Early in Spring remove the straw and work the soil. The plants which live will be the earliest in market.

The Royal Cheese Beaten.—"S. S.," of Locust Valley, L.I., says a cheese once sent from New-England to the President of the United States, weighed 3000 pounds, was twelve feet across, and could not be got into the hold of the sloop that conveyed it. If the cheeses were bigger in those days, the sloops certainly were smaller. When and where was it made.

To Prevent Milk Moulding.—H. B. Craig, Franklin Co., Pa. Milk will not mould in clean vessels, in a clean, *well-ventilated* dairy room. It is very apt to do so in warm weather in close, damp rooms, especially if they need whitewashing and are not in every respect perfectly clean and sweet. Soap and water and the scrubbing-brush, with whitewash often applied to walls and ceiling, are an effectual remedy.

Peas and Beans for Hogs.—"E. S.," of Dwight, Ill. These are much more used in the South than with us. The chief advantage of sowing peas is that it saves labor and gives a change of crop and of food.

Good Sheep.—T. T. Griffith, Md., has five sheep that sheared forty pounds of wool, and two lambs that dressed 102 pounds at three months old.

A Horse Pond, made by puddling with clay, should be the last resort for water, even for animals. A cistern under the barn is better. A well is better. Water brought in by a pipe is better. Warm, stagnant water, gathered from the surface, can not be much better for horses than for men. We plead for the poor dumb brutes.

Ingenious Method of Halter-Breaking a Colt.—J. C. M., of Lafayette Co., Wis., communicates the following plan, giving the credit of its invention to John L. Brown of the same county: "Tie a rope around a bay stack, then fetch your colt up to the stack, and tie his halter to the rope; there will be no danger of his hurting himself, or finding an unpleasant customer when he comes up to the scratch and gives in beat."

A New Dish for Stock.—It matters little what the new dish is, only let it *be* something new. Many farmers seem to think it enough to provide fodder sufficient in bulk to last through the winter, regardless of its variety. Every winter shows observing men that domestic animals become cloyed on the best of food, if confined long to one article. It is so with man. He craves a variety, and he must have it if he would continue in good health. Notice how seamen on long voyages are subject to attacks of scurvy or other maladies; and that chiefly because they are confined to nearly the same bill of fare, week after week. Experiments have been tried on dogs and cats and other animals, and it has been found that they sicken, languish and die, if kept an undue period on one kind of food. Obviously, the true course for the farmer is to lay in both enough and a variety of fodder. Hay to succeed stalks, and then roots to vary both, and meal to vary that, and so on. This will carry them safely and pleasantly through the long confinement of winter.

Hoof-Bound Horses.—A subscriber in Pleasant Valley, Pa., asks for a remedy. Dr. Dadd says, "A run at grass, in a soft pasture, the animal having nothing but *tips* on his feet, is the best treatment." Poulticing with soft soap and rye-meal is also recommended. This disease is often caused by paring away too much of the bars which support the heel, in shoeing.

Heavy Calf.—B. R. Prince, of Suffolk Co., L. I., writes to the *Agriculturist* that one of his neighbors, Mr. Henry Duthill, had a calf slaughtered when a few days less than fifteen months old, which weighed 666 lbs. It had never been weaned from the cow, and never drank any water. Breed not stated.

Saw-dust for Bedding.—"Farmer," of Winnebago Co., Wis., writes: "I have used pine saw-dust, and have noticed no bad effect on the hoofs of my animals, but on the contrary it appears to be a benefit. The only question with me is, whether it is a good article for manure. There appears to be a great difference of opinion in relation to the usefulness of pine saw-dust. Some are of the opinion that it is injurious to land on account of the pitch which it contains, while others think it injurious only when used fresh from the mill. Many of us farmers live in close proximity to saw-mills where we can get the dust for nothing, and if we were assured that it is a good article for land when well mixed with manure it would be of great benefit to us."

Taming Fishes.—T. M. F.," Franklin, Ind., writes to the *Agriculturist* that some of the fishes in a pond on his grounds will come to him on hearing his whistle, eat from his hands, and allow him to take them from the water.

New Straw as Manure.—"B. M. F.," Horsham, Pa. The absorbent capability of straw is an addition to its value, provided it can be used—i. e., if you have any liquid or fresh manure to compost it with; it is more easily plowed under, and rots sooner than when used dry. We know of no implement that will turn dry straw under better than the common plow. This is effectual if one follow with a fork to fill the furrow with straw.

Eaves-trough Tile.—"J. S. C.," of Haddonfield, N. J., says he tried them for ten years. With a constant flow of water they are durable.

Saline Incrustrations on the Soil.—One of our subscribers writing from Salt Lake City, Utah, says: We have many valuable tracts of land spoiled by the rising of a whitish efflorescence to the surface, (commonly called saleratus by the people). Can you inform the readers of the *American Agriculturist* in Utah, how to neutralize these alkaline deposits which destroy many crops?" The only remedy we can suggest is deep drainage. Thus in the season of heavy rains we might hope to remove the excess of salts so far that during the dry season (for in Utah the rainy and dry seasons prevail as in the tropics), capillary attraction will not be so likely to bring it up to the surface. Drains should be 4 feet deep and no further apart than is consistent with the most thorough draining of the whole soil.

A Garden Syringe.—"J. A. A.," Saginaw Co., Mich. Any tinner can make a garden syringe—take a copper or tin tube 2 inches in diameter, and solder on a head punctured with moderately fine holes; fit a piston or plunger to it with another head, wind the piston with tow and it is ready for use; if may cost $1.

Iron or Wooden Rollers for Cane Mills.—Mrs. F. G. Dickson, Kankakee Co., Ill. By all means use iron instead of wooden rollers for cane mills. The mills should be very strong, with iron rollers and iron cogs. Iron will not impart color to the juice while it is being crushed out.

Farm Mills.—F. H. Williams, Franklin Co., Mass., and sundry other persons, ask for information as to the practical working of the "People's Mill" formerly advertised in this paper. We know nothing from experience, having only seen it in operation at fairs and where offered on sale. We judge it better adapted for grinding *feed* than making *fine flour* for family use. The grinding plates are of iron and easily and cheaply replaced when worn so as to be ineffective. Shall we hear from some uninterested person who has had this or any other good portable farm mill running satisfactorily for some time?

Sorghum Sugar.—A very good sample of well-grained sugar, made on Cook's Evaporator, was sent to our exhibition-tables by Messrs. Rhymers, Bates & Day, of Mansfield, O. They write that the demand for Evaporators is so large, that though they are working their manufactory to the fullest extent, turning out from 60 to 75 Evaporators per week, they will be unable to fill all their orders this season. We believe Cook's is the only Evaporator which has successfully turned out sugar, in quantity.

Mayhew's Illustrated Horse-Doctor is one of the best recent publications on the treatment of disease in horses. The author has as ready a pencil as pen, and his descriptions are vividly illustrated by himself. The effects of disease are decidedly caricatured, but caricatures, whether of the pen or pencil, often present more correct views of facts than matter-of-fact statements or drawings. It contains 528 pages 8vo, with more than 400 illustrations. Published by J. B. Lippincott & Co., Philadelphia.

Illustrated Strawberry Culturist. Mr. A. S. Fuller, of Brooklyn, has put forth, in connection with his descriptive catalogue of varieties, a very excellent and valuable essay on the strawberry plant, its varieties, propagation, open culture, forced culture, inflorescence, the fruit, picking, marketing, preserving, &c. Sent by mail from this office, on receipt of 10c.

Annual Cyclopædia for 1861.—Appleton & Co., whose *American Cyclopædia* (now complete to SPI, and acknowledged to be admirably full and explicit,) has added so much to their previously high reputation as publishers, are out with a single volume of uniform size, (royal octavo,) with the American Cyclopædia. It is a record for 1861, of the important occurrences, in civil, political, military, and social affairs; containing a description of each important invention, of progress in Agriculture, in Science, in Mechanical industry, a view of financial matters, Biography, Statistics, Commercial matters, Public Documents of importance, and a very full *literary* record for the year. After a somewhat careful examination, we fail to find any omissions of important subjects. Such a volume is to be issued annually. For the present, the condition of our own country and the affairs of Europe give great interest and importance to current history. Published by D. Appleton & Co., No. 443 Broadway, N. Y. 780 pages, large 8vo; price, bound in cloth, $3.

Garden Book.—J. Moore, Sussex Co., Del. Hudson's Home Garden is a good general work, treating slightly on the small fruits. It really is a good, practical, modern hand-book upon the raspberry, one on the blackberry, gooseberry, currant, etc.

Not Right—"Gleason's Literary Companion."—This paper habitually copies from the *American Agriculturist* column after column of laboriously prepared original matter, including the Calendar of Operations, recipes, and the Basket matter, but instead of a fair, honest credit, it puts prominently at the head of the copied matter: "*Gathered for Gleason's Literary Companion.*" It is true that it usually adds to the last paragraph, as obscurely as may be, "*Am. Agriculturist,*" to avoid violation of our copyright. We submit that it is not doing the square thing. Mr. Gleason has long acknowledged that he finds the best matter in the *American Agriculturist*. If worth copying, why not give full and explicit credit? *Our* articles cost us brains and money. Please admit their origin plainly, or let them alone. A few other journals may well heed this, though sinning less than the one specially referred to.

Excellent Teeth.—Few people are aware how much good teeth, and their proper use, have to do with *health*. Food must be rapidly *dissolved* in the stomach, or it will not nourish and strengthen the body, but will, on the contrary, produce irritation, indigestion, and ill-health generally. The mashing and grinding *must* be done by the teeth, or the dissolving can not be well done in the stomach. A single sore tooth may prevent good mastication, and the unmasticated food produce indigestion, to be followed by debility, sickness, and ultimately bring one to an untimely grave. We are talking of facts, and not uttering fanciful theories. We therefore look upon dentists not merely as the promoters of the good "looks" of people, but as direct contributors to health and enjoyment. The little "plug" in a decaying tooth often not only saves the tooth to adorn the owner's mouth, but at the same time promote his health.—Those who have lost their teeth through their own bad habits, or from inherited defects, have much to thank the dentists for. Recent improvements have put it in the power of most persons to obtain complete or partial sets of teeth, equaling in beauty, and *almost* equaling in effectiveness the best natural teeth. Of all the modern improvements we think the invention of Dr. John Allen, formerly of Cincinnati, but now at 22 Bond-street, New-York, comes nearest to perfection. We took occasion to compare a full set of his manufacture with the best at the World's Fair in London, and with the best displayed in the dental establishments in London and Paris, and found nothing anywhere near equalling with them. By means of molds he beats a thin plate of *platinum* (the most infusible and incorrosive of metals) to fit the mouth exactly. To this plate is attached teeth every way natural in appearance (not so white or glistening as to appear artificial). A silicious paste, colored to the shading of the gums and roof of the mouth, is then laid upon the metal plate, and the upper part of the teeth. The whole is then melted in a powerful furnace to form a single mass which fits and adheres to the roof of the mouth so perfectly as to leave not the least appearance of artificial work. Even the natural corrugations and coloring of the roof of the mouth and of the gums is imitated. We have been intimately acquainted for months with persons having these artificial teeth, without suspecting the presence of other than natural teeth.

Baker's Glass Fruit Jars.—For simplicity, and yet effectiveness, these seem to be among the best, if not *the* best jars now offered to the public. They are simple and cheap—two important considerations. We have a number of them filled with strawberries and other early fruits, and they are doing well. The fruit being poured in, they are closed in a few seconds, by simply laying on a light fitting cover and putting on a clamp that with half a turn compresses the rubber ring, and closes the cap effectually. Manufactured by Potter & Bodine. See advertisement for particulars.

Pumpkin Pie.—The season for this luxury of Yankee land is come again, and so we must correct a recipe published on page 182, (June *Agriculturist,*) for making pumpkin pie out of turnips. Instead of 2 quarts of milk, use 1 quart, with the two peeled, boiled, and mashed turnips, 1 lb. brown sugar, 4 eggs, ½ cupful of molasses, ½ cupful of wheat flour, 1 spoonful ginger, and 1 nutmeg, seasoned and baked as a pumpkin pie should be.

Sowing Oats with Winter Wheat.—Geo T Roberts, Sussex Co., N. J. We consider it impolitic to sow oats with wheat if the wheat is sowed early enough to get well rooted before the ground freezes up, say before the middle of September. If sowed later, and sowed broadcast, mix the grain but sow on a still day. If the day be windy sow each kind of grain separately, using no more oats than you do wheat by measure. We have heard stated that very late sown wheat may be *drilled* in after oats are sown broadcast and bushed or harrowed in, and that it will thus do very well. The object of sowing the oats is simply to provide a mulch for the wheat during Winter, where it is liable to winter-kill.

Laying out Grounds.—"A. T.," Ky. Any work on landscape gardening will furnish the needed hints. Sargent's edition of Downing's Landscape Gardening is probably the best for an amateur. It is now out of print, but copies are often found in book stores.

Sewing-Machines at the World's Fair.—The machines which bore off prizes were Wheeler & Wilson's, Howe's, and two French machines, all in the same category. Wilcox & Gibbs', I. M. Singer & Co.'s, and several foreign machines, received honorable mention.

Good for Pennsylvania!—Canada thistles. We learn from our exchanges that the Legislature of Pennsylvania have made it a criminal offense for any one to allow Canada thistles to go to seed on his farm, and a fine of $10 is imposed upon each established complaint—and besides, after five days' notice, any one may enter another man's grounds, cut up the thistles, and recover full costs.

Raising Trees, Seeds, etc.

Nurserymen and private persons even, have hercofore been large importers of fruit and ornamental trees, roses, etc., most of which were obtained in France and England. Seeds too, and flowering bulbs have been brought in immense quantities principally from England and Germany, as also seed wheat from the shores of the Black and Mediterranean seas. Without discussing the policy of levying a heavy tax upon these importations, we will now only remark that the recently enacted laws laying a tax of 30 per cent. advalorem upon them will necessarily stimulate the home production. It can not be considered a lack of patriotism to advise early preparations to supply our markets with home grown articles. At this season should the seeds and pits of fruit trees be saved, as well as seeds of many of the forest trees, especially the evergreens, which should be collected and treated so as to secure the best results when planted. Farmers ought to save a larger amount of the best grain, corn, and vegetables, than usual, and take additional pains with the ripening seeds of those vegetables set out in the Spring. For several years past seeds have been so cheap that many farmers have preferred to buy rather than raise their own. This will no longer be the case—at least for some kinds. The lover of flowers also should see that seeds of the finest sorts are saved for another season. The wide-awake nurseryman will scarcely need the hint, but will at once make arrangements to raise his own pear, quince, plum and cherry and other stocks, most of which have hercofore been imported.

Laborers Wanted—Hint to Canadians.

There has recently been a large exodus of laboring men to the British Provinces, and we learn that in some parts of the Canadas there is an excess of this class, seeking employment on any terms. In the Northern States, on the contrary, there is likely to be a deficiency of efficient help, during a few months. The inducements to enlist directly, or as substitutes for those who cannot well leave their business, are now very large. The bounty for substitutes for nine months, will probably range from 6 to 12, *or more* dollars per month, *in addition* to the Government pay of $13 a month, and all expenses. This will be liberal pay considering that the liability to actual danger will be very small. Probably few of the nine-months men will be actually called into the battle-field, and if they were all so called, a man's chance, among 300,000, of being hurt, would be a pretty remote one. Even supposing that 10,000 out of 300,000 were killed or wounded, a man would even then have 299 chances of escape to 1 chance of being injured, which is about as good a chance as he would have if employed on the water, or on railroads, or among machinery, in peaceful pursuits. We take it, therefore, that if the draft be actually made, there will be a large number who will gladly accept of the chance to go as substitutes at $18 to $25 a month (including bounty,) among the reserve nine-months men, rather than to accept $10 or $12 a month at farm labor.

The hint we would offer, is, that men in the British Provinces will doubtless find it to their interest to come on and occupy the vacant places on our farms. We do not invite them here to enter the army, unless they *choose* to come for the pay offered, for there are citizens enough here to meet all demands. It will be well, however, for all who thus come seeking employment, to bring along some certificate of actual Canadian citizenship, for there is a generally-settled purpose not to empty those men who have "skedaddled" to escape military service. Persons seeking employment here should, therefore, be able to show that they do not belong to the class of returned runaways. If actual citizens of other countries, of good character, they will be welcome to the vacant places on our farms.

Agriculturist Crop Reports.

Breadth, Condition, and Prospects of the Principal Crops, Reliable Reports Gathered from the Whole Country.

On pages 282 and 283 will be found further condensed and very valuable reports on the state of the crops throughout the whole country. Excepting for two or three crops, the reports are, on the whole, very favorable. The following summary will be useful to those who have not the time and patience to examine the reports in detail.

THE WEATHER.—*A.* The average for the whole country, for the month ending August 10, is **10.6**—(10 representing the average for five years past.) The best weather is reported from the States of Minnesota (13½.), Missouri (13.), Wisconsin (10½.), Michigan (10¼.), Ohio (11½.), New-York (11.), and New-England (10.). In Indiana (9½.), and Illinois (9½.)

WINTER WHEAT.—*B.* The area as compared with last year is, for the whole country as **11.8** to **10.** This average prevails in almost all sections. In Wisconsin the area is 16¼, against 10 last year. In Ohio, 11½. In Illinois, 11.4. In Michigan, 13½.——*C*—The surface as compared with the average for five years past is, for the whole country, 13½, or one-third increase.—*D*—The prospective yield for the whole country averages **12.6**, that is fully *one-fourth* better than the average of other years! In the great wheat growing State of Ohio, the prospect averages over 16; in Indiana, 13½; in Wisconsin, 13. As these reports come from judicious observers, they indicate unmistakably that, for the whole country, with the increased surface (13½), and the excellent prospects (12.6), the crop of Winter Wheat is this year largely in excess of an average one. Here are the reports of the prospective yield per acre as they range by States: Ohio, 16.12; Indiana, 12.52; Illinois, 10.1; Iowa, 10.5; Missouri, 11.5; Nebraska, 8; Minnesota, 16.66; Wisconsin, 12; Michigan, 8.33; New-York, 11.15; Pennsylvania, 12.8; New-Jersey, 15; New-England, 9.2.——Extensive ravages by the "Chinch Bug," are reported in Dane and La Fayette Counties, Wisconsin; and also in Delaware, Cedar, Lucas, Linn and Madison Counties, Iowa.——The midge is reported as destructive in Orleans and Chautauqua Counties, New-York.

SPRING WHEAT.—*E.* The average area for the whole country as compared with last year, is reported at **12.4**, or about one-fourth more. In Illinois, where much Spring Wheat is usually grown, the area as compared with last year is estimated at 7.6, or about one-fourth less. In Iowa, it is 10.9.——*F*—The area of Spring Wheat this year, as compared with the average for five years past, is 17.8, or 78 per cent above the usual surface. In Illinois, this falls to 7, while in Iowa it rises to 25.—— *G*—The prospective yield per acre is, for the whole country, 9, or one-tenth below the average. Illinois and Iowa report only a ¾ average yield per acre; Michigan only ½ yield. The yield per acre, of Spring Wheat, will evidently be poor in those regions where this crop is most grown. The greater area will hardly make up the deficiency.

INDIAN CORN.—*H.* The average surface for the whole country is reported as slightly above that of last year. In the great corn State of Illinois, the area is put 9 per cent below last year.——*I*—As compared with the past five years, the area is this year put at 12.2 for the whole country. In Illinois it is 9¼, and in Iowa 20.8.——*K*—The *Prospects* of the corn crop to August 10, are reported good, the average for the whole country being 10.2. Illinois stands at 10, or just an average. This, with a deficiency of 9 per cent in area, indicates a smaller crop than last year. Taking the whole of the great western corn-growing regions together, the increase of area, and the average good prospects, indicate about the same crop as last year. An early or late frost will, however, materially change the final yield.

RYE—Column *L*, the area, and *M*, the prospects, indicate a yield about five per cent above the average, taking the whole country together.

OATS.—Column *N* represents the area, for the whole country, as being 12 per cent above the average; and *O*, the prospective yield per acre, as 8 per cent below; or less than average crop, on the whole. A considerable number of reports, especially from N. Y. and Penn., speak of much harm from the "Aphis," or "yellow insect." At the West, "rust" is complained of.

HAY.—Columns *P* and *R*, indicate the area, and the yield per acre, to be about 15 per cent above the average. In New-York State, the yield per acre is 9 per cent below the average.

POTATOES.—Columns *S* and *T*. For the whole country the area and prospects, range above the average.

FRUIT.—*Apples* (*U*) are very good in many States, the average prospect for the whole country being about 70 per cent above average years. ——*Peaches* (*V*) are reported very good, or, for the whole country 2½ times the average crop. The great apple growing regions report from a double to a triple crop, and few places anywhere report less than a double one.

SORGHUM.—Many reports from Ohio, Indiana, Illinois, and Iowa, represent a very large area. The prospects, in different localities differ materially, ranging from poor to double.

BARLEY.—Thirty-five reports represent a larger area in most States except Ohio, and good prospects except in Licking Co., Ohio, Howard Co., Iowa, and Chenango and Otsego Co.'s N. Y.

GENERAL SUMMARY.

A careful examination and comparison of the many hundreds of reports from all parts of the country, indicate that, taken as a whole, the present year has been unusually favorable to our great agricultural interests. There are local exceptions, in various sections, some of which are noted above, but these are not extensive enough to affect the general result.

The Foreign Harvests.

As we are now reasonably sure of a large surplus of breadstuffs in this country, an important question is, whether our surplus will find a foreign market, and on this subject we can speak with some degree of assurance. The Editor of the *American Agriculturist* has just returned from a trip through Great Britain, France, parts of Germany and Belgium, and reports:

"I found the wheat harvest in progress on the Continent. From what I saw, and from the statements of many farmers, I judge the yield to be below the average. The large area will in part make up the deficiency, but not wholly. In Great Britain the weather continued very wet up to the 24th of July, when a change occurred, and from that up to the 4th of August, the wheat crop continued to improve rapidly. But at the best, the damage to the growth by the wet weather all through the early Summer, can not be repaired. It is morally certain, therefore, that Great Britain will require a considerable amount of breadstuffs from abroad. Much of this could probably be obtained from the Continent at some figure, but not at the prices for which it can be furnished by the United States. My present opinion is, that our own surplus grain (unless unprecedentedly large) will mostly be taken at prices which will yield a fair remuneration to American farmers; but that *very* high prices can hardly be looked for. The present premium on gold is decidedly advantageous to the American grain markets. A gold "sovereign," counts at about $5 50 in the purchase of grain in America; in Russia, and Central Europe, it counts only as $4 75 or $4 80."

Home Again.

Unexpectedly, the writer has returned just in time to report himself in the closing editorial column of this paper.—After devoting some weeks to Great Britain, at the Royal Agricultural and Horticultural Shows, etc., we started on a tour through France, Switzerland, Germany and Belgium, intending to study the agriculture, and agricultural Schools of those countries. We had proceeded as far as Lyons, the great silk-growing region of France, when news came (by the way of *London*, of course,) that the principal army of our country was annihilated, that 75,000 men were *hors du combat*, and that the remnant of the army was about to surrender unconditionally. With such disastrous news, false indeed as it proved, but told as truth, our future journey lost its interest, and we immediately wrote to Liverpool and secured a passage to America in the first rapid steamer available. We felt it a duty to hurry home, if not to go into the army personally, at least to fill the place of some one who could do efficient service, to be ready to encourage our own brothers in the field, and to do all we could to promote the cultivation and profitable marketing of the greatest possible amount of the products of the soil, for the feeding our armies, and for sustaining our government.—But as hurried as was our journey abroad, by the diligent use of the time, and with unusual good health during every day's absence, we were able to see and learn much that will, we trust, be of future use to our readers. We have no intention of writing out a connected journal of our travels, but will drop a hint here and there, from time to time, as may seem desirable. O. J.

Our Country.

"Every Man to his Post!"

If one thing more than another would make us earnest in our efforts to preserve our country entire, it is the desire of the aristocracy of the Old World, everywhere manifested—and especially so in England—to see this great Republic of ours split up into fractions, with jarring interests and a prospect of unending strifes. Better that we make any required sacrifice of life and substance now, however great, than that our National Unity be dissolved, and war and discord be our perpetual heritage. We have recently stood upon some of the battle-fields of Europe, where the very soil is still fertile with the blood of hundreds of thousands of men—men slain in the wars concerning imaginary lines where Nature has made none. *Our* country has no natural dividing lines. Let us be forewarned against all attempts to set up artificial ones. Let every true American, native or foreign born, spare no effort now to preserve our country intact. It is even "sweet to die for one's country." Let "*Dulce est pro patria mori*" be the watchword of every man who would value a patriot's grave above an ignoble life in a country rent to pieces by traitorous hands.

FAT SOUTH-DOWN SHEEP.

Engraved for the American Agriculturist.

Whoever gives this picture the most casual glance, if he is at all familiar with the breed, will recognize the well-bred South-down; it requires no name under the cut. The straight, broad backs, broad loins, long, full quarters, fine heads, deep chests, the carcass round and well filled out back of the shoulders, the short, fine limbs, close fleeces, and the breadth of chest indicated by the distance apart of the fore-feet, all show this peerless breed of mutton sheep. Why is it that our animal portrait painters in this country, at least those whose pictures are engraved, so seldom succeed in giving any natural air and life to their productions? Perhaps the best talent is not often enough engaged. Portraits like the above, which might almost be called *bleating* likenesses, would be invaluable to a flock-owner who wanted to secure for his flock the notice and appreciation of the public. The sheep, and particularly the mutton sheep, occupies a place in economical husbandry, which can not be dispensed with, or supplied by any other animal. It is a great fault in American farming that over great districts sheep are so thoroughly ignored. They are an almost essential element in high farming; with their introduction, root crops to be fed on the farm; clover-lays fed off, and the sod, enriched by the droppings, turned under for wheat, the improvement and clearing up of wild and brush-grown pastures; tidy fences, and other evidences of good farming, follow almost as a necessity. We say, therefore, keep sheep, and if mutton is an object, keep South-downs.

For the American Agriculturist.

Cost of Harvesting Hay.

I had occasion to hire a meadow of nine acres the present season, and the notes from my field-book show the cost of the hay and of the harvesting, and also throw some light upon the profits of farming.

The rent of the Land was	$20.00
Cutting grass with horse-mower	6.50
Raking four hours with horse-rake	1.00
Curing and stacking seven tuns	7.50
	$35.00

This shows the cost of the hay in stack to be five dollars a tun. As it is worth fifteen, there is a profit of seventy dollars on the nine acres. But it is poor farming where grass yields under a tun to the acre, as in this case. Had the land yielded two tuns to the acre it would have cost no more to mow it and to rake it. The only additional expense would have been in gathering, which would not have exceeded a dollar a tun. From accounts kept several years, I have never been able to gather hay with the scythe and hand rake for less than three dollars a tun. The expense in this is but a trifle over two dollars a tun. The farmer who owns his horse mower and rake, I have no doubt can gather his hay for a dollar and-a-half a tun. What an infinite relief the horse mowers and reapers are to human muscles. It is cheering to see them appearing in new fields every year. CONNECTICUT.

The Fall Fairs and Cattle Shows.

These are likely to be held in undiminished numbers this season. Two years ago the cattle disease prevented the holding of many of these fairs, and last year the alarms of war either postponed them, or occasioned a thin attendance. But this year, notwithstanding the disturbed state of the country, and the multitudes that have joined the army, the usual number of fairs in the loyal States is likely to be held, judging from the premium lists and the announcements we have seen. This is as it should be. There is no good reason why the fairs should not be opened with their usual attractions. Our crop reports, embracing all the loyal States, show very conclusively that a larger breadth has been planted than in any former year, and perhaps we are justified in saying, that not an acre the less has been planted on account of the war. The demand for our breadstuffs in Europe, as well as the war, has stimulated production. Some probably have been influenced by the tradition that "high prices rule in war." Horses and machines have so far taken the place of human muscles in the field, that we miss the labor taken by the army far less than we should have done ten years ago.

Farm crops, on the whole, were never better, and the materials for a fine show are abundant on every hand. It is conceded that the wheat crop is a good deal better than the average; hay, with rare exceptions, is good, and grass abundant, which ought to put cattle in good condition. Fruit is plenty, which should make the horticultural department of the fairs unusually good. Manufactures in some branches are depressed, but there is the material for a good show in almost every county. Fairs which once might have been advocated as a farmer's holiday, have now become a necessity. They give a few days of recreation after the pressing labors of the Summer are over, and for this purpose they are worth all they cost. It does men of a common pursuit good to get together and have a celebration. It begets enthusiasm, and lightens the burdens of toil. But fairs are no longer mere holidays. They are schools of instruction, and no farmer can afford to stay away from them, and lose their benefits. He can hardly fail to learn something that will make his capital and labor more available for the next year. Here all the improved seeds, and tools for lightening the labors of the husbandman, are on exhibition. Here are the model animals that will turn the vegetable products of his farm into the most animal products for sale. So long as one cow will make more milk, butter, and cheese, from the same pasture than another, it will be a matter of great importance to visit cattle shows, and study the models. These fairs have already done a great work for the farming interests of the country, and, we doubt not, are destined to do a still greater. The shrewdest and most successful farmers are the steady patrons of these institutions, always present in person as careful observers, and sending in samples of their stock and crops.

The shows should lose nothing of their interest in a time of war. The ability of the country to sustain its burdens, will depend very much upon the prosperity of our agriculture. With our granaries full of wheat and corn, and our fields covered with flocks and herds, we shall be able to continue this war for years to come, if it be necessary. Let us go up to the fairs then in full force, old and young, and take with us the best samples of our handiwork—the products of the field, garden, and orchard, and the best specimens of our flocks and herds. There is pleasure and profit at the fair.

Hogs on Dung Hills.

The practice of keeping swine in a pen or small yard containing the manure etc. thrown out from the barn, is not to be commended. The hogs may find some fodder among the refuse hay and straw; they may improve the heap by turning it over and mixing their own ordure with the same; but we question whether it is a good thing for the swine. They become dirty and scabby, and sometimes lose essentially in vigor and health. Perhaps the injury comes partly from the heat and the gases constantly inhaled from the fermenting manure.

It is much better, we think, to keep hogs in quarters by themselves, and as clean and sweet as possible. Give them dry and commodious pens, with plenty of clean straw in their beds.

When to Sell a Colt.

A farmer makes quite as much money by selling at the right time as by cheapness in production. Stock as well as crops are kept too long for the greatest profit. A bushel of potatoes sold in July frequently brings a dollar; in September, forty cents, though the cost of production is the same. A lamb sold in time for three dollars, often brings more net profit than the fat wether sold at two years old. A pig will frequently bring four dollars at eight weeks old. At eight months well fattened, he will only bring twenty dollars, after eating twenty dollars' worth of provender. With this result it is easy to see the time to sell pigs in some sections.

It is not so easy to know when to dispose of a young horse. As a colt he may sell at weaning time, say four months old, for twenty dollars, or fifty, if a handsome animal. It has not cost much to raise him, for he has lived on his mother's milk, and she has paid her way by her work. But when he is put up for the winter, his keeping begins to count. He can do nothing in the way of self support until three years old, and it were better perhaps not to work him much even then. If well kept he can not cost much less than a hundred dollars before he is fit to work, in any region where hay is worth fifteen dollars a ton. He may sell for three hundred dollars or more, but the chances are that he will sell for no more than the cost of his keeping. The farmer may not lose any thing, but he will only have made a fair market for his hay and pasture. In the sale of a colt during his first Summer or Fall, the price is nearly all profit. There is little risk about it, and the venture is made a certainty. If the sire be a blooded animal, the colt will generally sell for enough more to pay for the price of his services, and often to pay for them many times over. It is most in keeping with our calling to make the profits sure, though small.

Cattle-Comforts.

MR. EDITOR:—I hear and read a great deal about having good horses, fat cattle, and the like: also, a good deal about feeding them on this or that, but I don't hear much about trying to make our stock comfortable and positively happy. I want *my* cattle and horses not only to live, but to enjoy life as they go along, just as their master does. A really good-hearted man will take pains to please and gratify his domestic animals: he will strive to attach them to his person, so that they will know his voice and step, and always be glad to see him. Do you get my idea?

Well, this is the way I work it: In cold weather, I see to it that my cattle have wholesome food, and as much of it as they will eat up clean. I see to it that they have a variety, also—hay of various kinds, oat-straw, corn-stalks, roots and grain, cooked and uncooked. Milch cows, fatting cattle and working cattle, all thrive best and keep happy on a variety.

Of course, I don't neglect giving them comfortable quarters, whenever they need shelter. Come out here, Sir, and see my stalls and my sheds, and my dry, well-littered yards, if you doubt. Experience shows me—and I know you teach the same doctrine—that stock will eat about twice as much fodder, if they are kept out in the wind, and pinched with the cold. But, letting go the dollars and cents, I want to see my family, rational and irrational, happy. So I go in for good quarters. In addition to this, temperance man as I am, I believe in good drinks for my stock. I won't compel them to wade a half mile through mud and snow to a stream of water, but I have got up a penstock in a clean corner of the yard, which pours into a large tub, and the overflow goes into a long trough, so that quite a number of cattle can drink at once. My cattle are salted once a week regularly the year round. Some people keep it afore them all the time; and some cattle never see it.

But this in the general. Besides this, I go out of my way often to please my friends at the barns. In the Summer, I seldom go into the pasture without taking along an ear or two of corn, or a handful of oats, to give to the first horse or cow I meet: and I'm sure to meet some creature in double quick. They flock around me as soon as I come into their domain. And when I go out to the barn to harness a horse or to yoke up the cattle, I take into the stall a sweet apple, or something else that will please the poor creatures. I speak pleasantly to them, and caress and fondle them. Be sure I do. In this way, they become gentle and kind, and are plainly much attached to me. None but a fool or a hard-hearted man will doubt that they are made happy by such treatment. Now, when I deal so with my horses and oxen, they will do for me whatever service I ask. When they are at work, I give them to understand that they must mind, and they always do. But I never over-work them. I have lived long enough to know what a fair load is, and I never mean to tax them beyond their strength, nor work them for too long a time. In this way, they learn to confide in me; they never revolt, but work cheerfully.

A COMFORT-LOVING FARMER.

Tim Bunker on Swamps Turning Indian.

"So you see it's turnin' Injun agin," said Deacon Little, as he looked into the horse-pond lot where I was mowing with the machine.

"I guess you did'nt make so much eout of me in that bargain as you tho't for, Squire Bunker," said Jake Frink, as he joined the Deacon at the fence a few days ago.

"What evidence of Indian do you see in this grass?" I inquired.

"Plenty on't," answered the Deacon. "There's dock, and rushes, and brakes—I told you so. I never knew it to fail. A reclaimed swamp allers turns Injun arter a year or two."

"And you hain't got morc'n half the grass you had last year," chimed in Jake Frink. "Neow Squire, I du say, if you're sick of your bargain, I'll take that lot back agin at jest half the price you gin me—and that is mighty fair."

"How much hay will I get here to the acre think you?" I inquired of Jake.

"Wall neow, naber, it'll be tight squeezin' to git a ton and a half, and the first crop was three tun three year ago."

"And that tun and a half," I replied, "will be worth $35. Taking out $5 for cost of harvesting, and four more for interest of land and cost of manure, it leaves $18, or the intcrest on $300 an acre. Should I be a wise one to sell it for $10 an acre?"

"But see them rushes and brakes, Squire Bunker," exclaimed the Deacon, "You see the Almighty made that a swamp, and I guess you won't make any thing else eout on't if you keep tryin' from neow till doomsday."

"Well, Deacon, you see nothing else grew here but such things, and sour grasses, four years ago, and since I put in the drains, and stocked it down, we have had less of them every year. There is a hundred pounds of good hay where there is one pound of such stuff. You can not expect sile that is full of old brake roots, and rushes, to say nothing of foul seed, never to show a sign of the old vegetation."

"Nothin' will come of it. You never can make upland where the Almighty has made a swamp."

"That's so," responded Jake. "Better take $10 an acre, and trade back. It will be all moss another year—see if it ain't."

This talk of a July morning shows pretty well the prejudices of some of my neighbors against draining. They want to find an excuse for doing nothing, and thus set up a standard for reclaimed land, that they would not think of applying to land that needs no draining. If it shows any remains of the old grasses, and rushes, it is of course going back again to swamp. If it don't contiuue to bear three tuns of hay to the acre, they hail you with, "I knew it would be so; the land is running out."

Now I hold, that we ought not to expect any more of reclaimed land than we do of any good upland. If it performs as well as that, it is clear enough that draining pays. No upland that I have ever cultivated will keep up a yield of two or three tuns to the acre, without manure. It is very good land that yields a tun and a half three years after laying down. I never expected the horse pond lot to do any better, but it has disappointed me in this respect, and has held out better without manure than any undrained land upon the farm. I should have given it a top-dressing last year, if I had not wanted to see how it would hold out. The yield was quite two tuns, though Jake Frink saw a quarter less. With manure I can get three tuns easier than I can get two upon upland.

The rushes and sour stuff that Deacon Little makes such a fuss about, grow smaller every year, and will soon disappear entirely. There is, however, a need of one more drain in this lot, to make perfect work, and that I calculated on when I began the job. I did not carc to be at the expense of puttiug it down unless it was necessary. It was just fifty feet betwecn the last two drains I laid down, and I can see now that it needs another just half way between. It has always been too wet along this middle line, the grass has not been so heavy, and it is here that the brakes and rushcs are found principally. It is as clean as ciphering can make it, that there ought to be another drain there. Indeed, I have lost considerable money by waiting so long, say half a tun of hay annually for three years. But what I have lost in money I have gained in knowledge. It is worth something to know just when and where to drain. For such land as this twenty-five feet is none too near, and three feet is none too deep. I would drain three inches deeper if I could get the fall. But three feet makes very good work, and land so drained I am sure will never turn Indian.

I never was fool enough to suppose that such land would keep up to three tuns to the acre without manure of some kind. But some men demand this, and because drained swales and swamps will not take care of themselves, they think draining a failure. This is unreasonable. Parson Spooner preached a few Sundays ago about "not muzzling the ox that treads out the corn," applying it, among other things, to giving a good bounty to the soldiers. You see, Hookertown took the hint next town meeting-day, and voted $100 to every man that would enlist. I thought the truth would apply to the sile, as well as to soldiers, and oxen. It is about the best worker man has got, and we have no

business to starve it. I suppose I ought to have been thinking of something else on Sunday, but the application hit my case so exactly, that I made up my mind right off that I wouldn't muzzle the horse-pond lot any longer. It got a dose of manure right away after mowing, without fail. The grass looks as green as a leek now, as much as to say, "Thank you, Squire Bunker, for your kind attentions."

But Mrs. Bunker's mind took another tack, thinking, I suppose, how the bounty was going to help enlistments, and that the new soldiers would help John down on the James river; she thought it wan't worth while to have Parson Spooner muzzled after such a sermon, and hinted that I had better leave a barrel of potatoes and a hind quarter of lamb at the parsonage next day. Well, you see, that was a scriptural application of the doctrine, and as I believe in facing the music, I left them, and added a bag of corn on my account, and a beef ham, that he might know that the oxen and corn part of his text at least was remembered.

But to return to the subject, as Mr. Spooner sometimes says in the pulpit, I think we make a great mistake in not top-dressing our meadows oftener, say as often as once in two years. In a small lot of an acre and a quarter, where I cut four tuns last year, I only cut three this, and the only difference was in manure. Five dollars worth of compost would have made a difference of at least one tun of hay.

Deacon Little and Jake Frink are mighty afraid of having too large grass. Jake often says that he had rather have "two tun than three to the acre." Now I don't believe this notion, that heavy grass makes less nutritious fodder than light. A beef steak out of a corn-fed ox is enough-sight better than one out of a thin grass-fed animal. Why should not grass from a well-fed soil be more nourishing. I have watched this thing at the manger pretty close, and have grown three tuns and a half to an acre, and I have never yet got hay so big that the cattle would not eat it up clean. Cut your heavy grass a little earlier, and cure it well, and there is no trouble about making good fodder. A well drained, corn-fed sile never turns Indian, Jake Frink to the contrary notwithstanding.

Hookertown, Aug. 15th, 1862. } Yours to command, TIMOTHY BUNKER, Esq.

For the American Agriculturist.

Experiments with Concentrated Manures on Grass.

MR. EDITOR:—Will these manures pay? This is the question. To test it I measured off four-rod plots on a piece of old meadow that had been hard cropped for years without manure. It had produced in past years not over three fourths of a tun of hay to the acre. The plots ran from the road off toward the middle of the meadow, and were intended to be as near alike as possible, though the result shows that plot 1, next to the road, was a little above the average. The manures were sown on the 17th of May, broadcast, without any composting, as in the following table:

No.	*Quanty.*	*Value.*	*Weight of hay.*	*Value of hay at $15 p. t'n*	*In- creased.*
1—Nothing.....	..	..	62 lbs.	.46	.. lbs.
2—Peruvian Guano	17 lbs.	.50	108 lbs.	.77	54 lbs.
3—Fish Guano.....	40 lbs.	.59	73 lbs.	.54	33 lbs.
4—Lloyd's Sup'phos	21 lbs.	.59	49 lbs.	.36	.. lbs.
5—Mallp'ed Guano	21 lbs.	.59	92 lbs.	.69	45 lbs.

It will be seen that the weight of hay on No. 4 is less than that on No. 1, which is pretty convincing proof that No. 1 being next to the wall was more than an average. The superphosphate of lime, though a brand of high reputation, produced no effect whatever. I have therefore assumed 49 pounds as the average yield of the plots without any manure. The yield is the best in the case of the Peruvian guano, and the manipulated and fish guanos stand next in order. In no case does the manure pay the first year, if the value of hay is reckoned at fifteen dollars a tun.

The failure to make these fertilizers pay the first season I attribute to two causes, the lateness of the application, May 17th, and the lack of absorbents. In experiments made several years ago the guano and superphosphate of lime were mixed with charcoal cinders, and applied April 4th during a rain. But in this case no absorbents were mixed with the fertilizers beforehand, and no rain fell for ten days after the application. Probably some of the ammonia was lost, and doubtless some of the strength of the manure will appear in the aftermath, and in the grass next year. In the use of the fertilizers with absorbents, and in an early application, there was shown to be a clear profit above the cost the first year. The experiment goes to establish the following positions:

That concentrated fertilizers should have absorbents mixed with them before application. That they should be applied early in the season as a top-dressing for grass. That it is still a doubtful matter whether they can be made to pay the first season they are applied.

JONATHAN.

Two Strings to the Bow.

It is the practice of large farmers, in some parts of the country, to devote their entire energies, and the resources of the farm, to only one or two crops annually. At the extreme South, it is cotton or sugar; in other States it is corn or tobacco. At the West, it is often wheat or corn; and at the East, in some districts, it is hops. In Ireland, the potato crop is the main reliance of the hungry population; and when that fails, famine stares them in the face. England relies so much on her grain crop, that a failure of it begets a panic.

This plan works well, at home and abroad, *provided* the season is entirely favorable to the particular crop. But untimely frosts will come, notwithstanding our plans and expectations; insects will revel in the immense fields, however valuable in prospect to their owner; unseasonable rains will fall; rust and worms, and manifold other evils will beset us on every side. And when the calamity comes, it is a great one. We have intrusted our fortunes all to the keeping of one frail boat, and when that goes down, all our hopes are wrecked. Who does not see that in this course of farming one is incurring too great a risk? It is like investing one's whole fortune in a single kind of railroad stock, and that very unreliable. It is a sounder policy to distribute one's chances over a wider surface. It is far safer to raise three or more different crops; then, if one or more fail, there is yet something to fall back upon. It is very true, that this does not make so great a show for an ambitious farmer. The proceeds do not come in all at once, in so large amounts, as when a single great crop is gathered and sold. But in the long run, the proceeds are larger, as they certainly are surer. It is better to have five years of moderate and regular profits, than one year of large gains followed by four years of losses. Better, so far as the mere money results are concerned; better for one's habitual peace of mind, and better for one's morals.

When the mania for any kind of speculation prevails in the land, a few large fortunes are made, but many men are ruined. Money become suddenly rich, and then as suddenly poor. Sagacious and observing financiers tell us that the most successful and sure way to amass property is to avoid all unnecessary risks, and to be satisfied with steady and small gains. Apply this to agriculture. Well has one written: "A farm which depends for its profit on butter, fruit, cheese, timber, cattle, hogs, corn, wheat, potatoes, flax, etc., makes, perhaps, but a little on each crop; but the rains which come in *drops* are useful, while those which come in *torrents*, and raise freshets, leave great mischief behind."

Reclaiming Salt Marshes—The Object to be Gained, and How to Do it.

The reclaiming of salt marshes is every year attracting more attention among our shore farmers, and the work is so simple, and the results so lasting and valuable, that nothing is wanting but a knowledge of the details of this business, to lead to the reclaiming of thousands of acres of now worthless lands. The impracticability of growing upland grasses upon them rests upon the fact that the tide rises and falls, in the streams and creeks that pass through them, every twelve hours. The hight of the tide varies considerably, not only at different phases of the moon, (the full tides coming with every full moon) but in different localities. Thus the average tide at Throggs Neck, L. I., is some two feet higher than at Watch Hill, at the East end of Long Island Sound. The difference between high and low water increases as you go westward, along the shores of this Sound. Of course marshes at the west end admit of a greater fall of water, and can be drained deeper than at the east end. But as the difference is three or four feet between high and low water in the least favored spot, there is no lack of fall that will prevent drainage in any salt marsh.

Most of these marshes are actually above the tide four fifths of the time. It is only in heavy easterly gales, and at the full moons, that the water covers them. The full sea at other times will not even make the ditches bankfull. The object to be gained by an embankment and tide-gate is, to shut off the access of the salt water altogether, or at least to confine it to the creek and ditches that may be made for the purpose of drainage. Simple as the idea of a tide-gate is, we have rarely found a person who had any idea of the mode of their operation, if he had not seen one at work. Twice every day the salt marsh is flooded and again drained, by the action of the tides. Were the tide to be shut out, fresh water would accumulate more or less within the dike. In heavy freshets there might be a very considerable accumulation of water, but it would be fresh, and might stand for hours, or days even, upon the land without damage. If a dike or dam be built high enough, tight enough, and strong enough to shut out and keep out the sea, and only a single sluice or flume be left through which the water can flow, and this flume be so constructed that by the action of the water a gate will close it the moment the water tends to flow in, while when there is no pressure on the outside the gate freely opens to let the water out, the whole is accomplished.

The engravings represent different views or "elevations" of a tide-gate built recently by Colonel L. B. Hanks, at Mystic, Conn., which has completely shut off the tides from about three acres of marsh, which he is laying out as a

lawn. As the tide-gate presents the main difficulty to those who are thinking of making this improvement, we give a particular description.

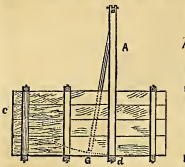

Fig. 1. Fig. 2.

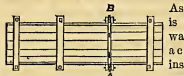

Fig. 3.

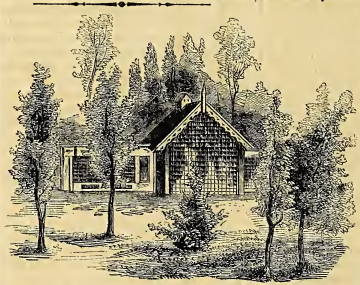
As the object is to give the water which accumulates inside a single passage out, and perfectly to exclude water from without, there must be a water-tight flume or trunk in which, or against which, the gate swings. Fig. 1, represents the side elevation of this flume, ten feet long and five high. This crosses through the embankment or dike, and must be made water-tight on the outside by a framing of plank, and by packing some tenacious earth—clay, or clayey soil—around it—called in engineering, *puddling*.

The gate, *C*, is suspended from the top of the uprights *A*. *B*, the hinge being the cross piece. Fig. 3 shows the bottom of the flume, and the manner in which the planks are spiked on to the frame. The side elevation shows the gate as pressed outward by the current, when the tide is falling. When the tide rises the gate is pressed from *c* to *d*, where a strip of plank is nailed at the bottom and sides of the flume, at *d*, making, as nearly as possible, a water-tight joint when the gate is closed. The planking is merely jointed or rabbeted together; all else is left in the rough. The material for the whole is chestnut. The sills, caps, and posts are 3x4 inch stuff, the gate posts 4x6, and the gallows posts 2x3. Two inch planking is used for sides, bottom and gate. The cost for lumber and carpenter should not exceed fifteen dollars. This thickness and size of material is enough for a tide-gate, where the rise and fall is not over six feet. The higher the tide rises, the stronger the gate, flume and dike should be made.

The embankment here is made in the following manner: First a ditch is opened along the line of the dike two feet wide, and going down to the hard pan, which in this marsh is about three feet below the surface. The sod taken from the ditch is placed grass side out, for the outer wall of the dike, making a terrace two feet high along the whole line. The rest of the contents of the ditch are piled up against the sod, to strengthen it. The ditch thus cleaned out is filled with yellow loam or any clayey soil, and packed hard with a rammer to make it impervious to the water. A bank of the same material is raised above the top of the ditch some eighteen inches, and packed in the same manner. Four or five feet from the inside line of this ditch another is dug four feet wide. The sod is taken for the inside wall of the dike, and to finish up the outer wall. The contents are also put upon the embankment. The whole is finished off with gravel, or any convenient soil, on top, making a fine walk. By enlarging the dimensions of the dike, it may be made a carriage-drive or cart-path, with decided advantage to its solidity. As nearly all the material for the embankment is found upon the spot, the expense is much less than one would suppose. The cost does not exceed two and a half dollars a rod. One of the advantages of this kind of embankment is that it grows stronger with time. The turf upon the outside being washed with the tide, soon knits together by the growth of the marine grasses, and presents all the attractions of a green terrace. It should not be forgotten that the width and hight of the dike must always be proportioned to the hight of the tides. In some places an embankment six feet high and ten feet across will be none too strong to resist the pressure of the high tides. As the whole success of reclaiming these marshes hinges upon the permanence of the embankment and of the tide-gate, no pains or expense should be spared at these points necessary to secure good materials and thoroughness of construction.

We are glad to learn that the hints thrown out by this journal upon this improvement have been very highly appreciated, and that these waste lands are beginning to absorb some of the spare capital of our farmers upon the coast. No class of lands present a more inviting field for industry, or offer a surer prospect of reward.



Some Hints about Hen-Houses.

The profit of a good hen-house is realized in the winter. All hens will lay in the Spring and more or less in the Summer and Autumn, but only these which have warm, well lighted, comfortable, well ventilated houses will lay in the Winter. The present is a favorable time of the year to put up a hen-house, or alter over, repair, whitewash, and put in order old ones.

In order to succeed with poultry, they must be clean, well fed, have comfortable roosts and nest boxes, warm but well ventilated quarters, and yard room. They may not be too crowded, nor subject to scares, or handling. Neither may great numbers be kept together. For the comfort of the poultry-man things must be conveniently arranged. And to gratify his taste all should be architecturally appropriate and handsome. Expensiveness is not an element of beauty, and particularly in things of straight-forward practical utility. To most minds it detracts from the enjoyment of an otherwise excellent structure. Some natural, simple ornamentation is well.

The amount of space to be allowed to each hen is variously estimated. If the house be 12 feet deep from front to rear, and the hens have a good yard, there may surely be as many hens kept as the house is feet long, and in our opinion twice as many. That is, a 12x20 house will accommodate 20 hens at least, and we think 40 as well as not. Each hen will then have about 6 square feet of floor room; and if the room is 8 feet high, 48 cubic feet each, which is equivalent to a coop 3 feet 7 inches square and of the same hight. We would not keep more than 40 or 50 hens in the same apartment. It is much

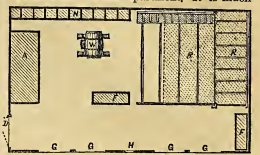


Fig. 2—PLAN FOR A HEN-HOUSE.

Explanations.—*A*, ash-box; *D*, door; *F*, feed boxes; *G*, glazed windows; *H*, hole for ingress and egress of hens; *N*, nest boxes; *R*, roosting ladders—the one with short rounds fixed, the other hinged upon it, and capable of being lifted up horizontal in hot weather; on one end of this is a cleat-ladder, to be put under when the ladder is in a horizontal position. The dotted shading under the ladders represents the muck on which the droppings fall, and are composted.

better to divide them and prevent communication entirely. When too large numbers of hens are confined together, disease in various forms almost always breaks out among them, destroying the profits. The hen-house must also be light. It can not be too light. The cut we give of the poultry-house put up by Mr. Bement, the famous poultry-man, for Mr. Vassar of Po'keepsie, has the entire front of glass, even to the peak of the roof. It is frequently convenient to adapt room in the barn or some out-house or shed to a hennery. This is often better than building a separate structure, for it is warmer, and easier reached in stormy weather. The best floor for a hen-house is a cement one, in which there is an abundance of small stones. In a hen-house 20x12 and 8 feet high, there should be on the floor a dust box to contain ashes, which should be about 6x2½ feet, and a foot deep; a tier of nest boxes extending

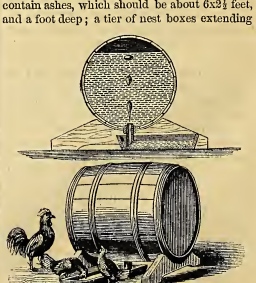

Fig. 3—A WATER FOUNTAIN.

across one end or on the back side of the room, one foot wide and ten feet long; a feeding box or two which would occupy about 3 square feet each; a water trough or fountain taking two

more square feet, and finally a pile of muck or earth under the roosting ladders about 8x8 feet. Thus fully 2-5ths of the floor would be occupied, leaving none too much space to get about conveniently and take care of forty hens.

The roosting ladders should be horizontal and fixtures—at least one should be. The plan is very good to have one ladder 3 feet wide, and for such a house as we describe, about 8 feet long, supported level about 6 feet high (or not nearer than 2 feet to the ceiling) in one of the rear corners of the room and along one end. The rounds should be an inch and a half in diameter, and about 14 inches apart. A post will be required, or a wire from the ceiling, to support one end. Against this ladder another may be fastened, extending from the floor up to the fixed ladder and hinged upon it, so that it may be lifted up and fastened in a horizontal position. The ladder should be a little over eight feet long and the rounds two feet apart, the upper one being two feet from the end.

The water fountain, (fig. 3,) is a very convenient way of supplying poultry with water. It is a simple contrivance, consisting of only a tight keg-barrel, with a hole in the bung, and a tube of elder with the pith punched out, inserted. The barrel is filled with water, the bung and tube put in tight, placed so that when it is rolled over to its place in the frame, the bung will be undermost, and the tube will reach nearly to the bottom of the earthern pan or trough set below. The water will flow out, as the air bubbles ascend within, as shown in the upper section. As soon as the water closes the mouth of the tube, no more air can get in, and no more water will flow out—so the supply will be constant until it is all gone. A large bottle inverted, the neck being passed through a hole in a board nailed across the top of a trough, will answer for a small flock, or a coop—very well.

Reclamation of Swamp Land.

Some time since we received from the Southboro' (Mass.) Farmers' Club, a statement made by Peter Walker of that place, with reference to some successfully-reclaimed swamp land. He had purchased the farm about two years before, the greater part of it being covered with small wood brush and brakes; at the time of making the statement it was nearly all reclaimed, and producing annually at the rate of two tuns of excellent hay to the acre. After having thoroughly drained it, so that the water was lowered *at least* two feet from the surface of the muck swamp, he proceeded as described by himself, in the following extract:

"My method is to dig it up with the breaking-up hoe, for it is impossible to plow it until the sod is rotted. I have dug more or less for 7 or 8 years, usually soon after haying is over, planting with potatoes two years, when the sods are sufficiently rotted to seed down to grass. I put a small quantity of raw manure in the hill for potatoes, and before seeding down, in the winter, I carry on gravel to give the surface a covering of about three inches, and when the frost is out of the surface sufficient to get in the seed, I sow and harrow in Herdsgrass seed and nothing else, and without manure. In the Fall following I spread on compost manure.

"In August 1859 I dug up half an acre, more than half of which was covered with a hard brake sod. In September following I turned the sods over to prevent the grass and brakes from starting up. The first week in May following I planted the piece with potatoes, carried out raw manure with the wheelbarrow, put a small quantity in the hill, and covered the potatoes with the sods, some of which were sufficiently rotted for that purpose. Hoed them twice, making the hills entirely of the sods. Dug the potatoes in September last, and the average yield was a bushel to nine hills—about 380 bushels per acre, the hills being about 3½ feet apart each way. From my experience, I am firm in the belief that the true way to succeed in reclaiming swamp muck land, is, to drain so as to drop the water at least two feet, (or better, three feet,) then plow, or dig up with a breaking-up hoe, and let the sods rot, instead of burning, or covering at first with gravel or sand as many do."

Bag Holders Again.

We have given several descriptions of contrivances for holding bags, (Vol. XX, p. 363, and this volume, p. 44,) having vivid memories of aching arms in our boyhood, and of blame often worthily bestowed for having failed in our own performance. So it is in no small degree from our sympathy for the boy bag-holders that we give our readers descriptions of two inventions which we have no doubt are excellent. The first is Hostetter's patent, made by J. R. Hoffer, Mount Joy, Pa., and is very easy to understand. On the front of a light truck, about 3½ feet long by 11 inches wide, a frame is attached, having at the upper end two stout divergent wires projecting as shown in the cut. The top edge of the bag is turned over these wires, and held firm by the two flat, wedge-shaped buttons which turn down and wedge in between the frame and the wires. The frame may then be raised to accommodate the length of any bag not more than four feet long. When so raised, it is held in its place by the cord and ratchet-wheel seen on the right hand side of the truck. When filled, the bag may be wheeled off wherever desired. Such a truck bag-holder must be very desirable wherever many bags are filled and moved, particularly in mills and country stores.

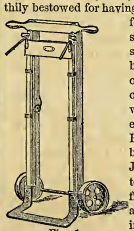

Fig. 1.

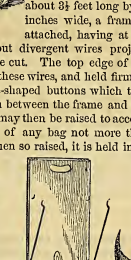

Fig. 2.

The second is a home-made bag-holder, a description of which is received from a subscriber to the *Agriculturist*, Mr. J. Moore, of LaSalle Co., Ill. We give a description of it nearly in his own language, premising, however, that we have made a slight addition to the sketch sent, in attaching the foot-piece or base to the upright.

"I herewith send you for the benefit of your readers a description of a bag-holder of my own invention, which I have used for some time, and like it much. It holds a bag better than any boy can hold it, and is so simple that a farmer can make one in half an hour, of material costing less than a dime. As grain bags are generally of uniform length, it is not necessary that the hooks should be movable up and down, and the spring of the long wires will adapt the holder to bags of any width. *Description*—It is simply an upright board, 4 feet long, and 14 inches wide, which must be fastened in a perpendicular position, either by nailing it to the side of a box or bin, or by securing it to a base of some kind. There are seen four hooks on which the bag hangs while being filled, two short ones upon the board, just high enough to let the bag touch the bottom. The other long hooks are of wire, one sixth of an inch in diameter, and 18 inches long, with a short crook and sharp point at the top, (shown *enlarged* at one side); the lower ends are driven into the edge of the board, and the upper ends standing out 5 or 6 inches in front, 2 inches lower than the small hooks."

Drilling Wheat—Drills.

There is scarcely any operation of farming concerning which practice, in different parts of the country, varies more than in this. The grain drill is a rare sight in New-England, and rare also in many parts of the Middle and Western States and Canada. Still, wherever its use is common, it is held in very high estimation. In saving seed alone, a drill more than pays the interest on its cost. The risk of winter-killing is greatly diminished, and an even seeding is readily secured. In the following communication from Mr. A. Linton, of Chester Co., Pa., written in response to a request from ourselves, the advantages are very simply and strongly set forth, and deserve the attention of every wheat grower who does not use the drill:

THE USE OF THE DRILL.

To say any thing advocating the use of the drill in sowing wheat in this section of country, would be as superfluous as to discuss the excellence of anthracite for fuel, or the utility of steam as a motive power. The use of the wheat drill is so nearly universal here on all land where it can be used, that the sight of a field sown in the old fashioned broad cast way is a rare occurrence.

The advantages of drilling wheat may be very briefly stated as follows: it distributes the seed more evenly over the ground than is generally done in broadcast sowing; the wheat is not so liable to be thrown out by the freezing and thawing that occurs here during the winter; the depth at which the seed is placed in the ground can be regulated to a certain extent, as the moisture or dryness of the soil may require, to insure its speedy germination. It takes less seed; the crops look better, and ripen more evenly than if sown in the old-fashioned way; and lastly, the use of the drill insures a more thorough preparation of the ground previous to seeding, being a good cultivator itself.

As to the points to be possessed by a good drill: It should supply the seed regularly and equally to the separate drill tubes. The grain, as it drops into them, should be plainly in view, that the operator may see at a glance that they are all working properly. It should not be liable to clog so as to prevent the regular flow of the seed. It should have an index to mark the quantity of ground sown, and a fixture enabling the user to regulate the amount of seed per acre. There should be a contrivance to raise all the drill tubes off the ground when turning; each should work independently of the others, and be so attached that its angle of inclination with the ground may be altered to regulate depth. The drills should be eight inches apart, (some prefer nine,) and eight in number. A good seed-sower should be attached, so that grass seed may be sown at the same time the wheat is. These points are possessed by all drills of recent manufacture used here, though there are many different mechanical contrivances to secure these ends. Drilling oats succeeds admirably sometimes but

often fails. The cause of failure I think is owing to drilling the seed too deep; the ground at that season is cold, and seed placed too deeply in the soil is a long time coming up; the plants are stunted, and never after become vigorous.

The corn drill is much used, though not universally. Many farmers still prefer to plant with the hoe, alleging that the growing crop is more easily worked and kept clean, and that it is less difficult to thin out to the right quantity. The extra labor in working drilled corn, is more than balanced by the extra work in marking out the ground and planting with the hoe; but it requires more judgment to thin out drilled corn right, than it does when planted with the hoe. Drilled corn is generally not so much disturbed by birds, as they so often fail in getting the grain, and, if properly managed, will produce more per acre than when hoed in.

Experiments in Wheat Culture.

PLANTING IN HILLS AND HOEING.

Like all other plants, wheat responds promptly to careful tillage, and what the limit of the amount of labor is which will pay, no one has yet ascertained. Up to a certain point, or perhaps rather to an *uncertain* point, the more labor and care bestowed the better will the crop pay. A correspondent from whose letter we quote below, and several others also, find the regular hoeing of wheat to pay. For our own part we have no doubt it will pay for seed wheat, and can confidently recommend the practice of planting a patch to be thoroughly hoed, weeded and cultivated for seed. Before the cutting, the largest and finest ears should be culled, care being taken to secure enough to have sufficient seed for a similar patch another year, even though the largest and plumpest grains only shall be selected, for these alone should be used. All the grain from the seed patch would be good enough for field sowing, and indeed much better than any that could be obtained by screening in the usual way. These ears culled should be the earliest and largest, from those stools which had thrown up most stalks; and the grains sowed again should be the plumpest and largest out of these ears. We give here the experiments of Mr. S. Ransom, of Ashtabula Co., O.

"On the tenth of September 1859, I planted one acre of wheat, in hills one foot by two feet apart, put four kernels in each hill, and covered them with the hoe the same as Indian corn is usually planted. I cultivated it with the hoe on the 15th of October, and again on the 16th of May, with the horse and cultivator and the hoe. The soil is loose gravel of poor quality, except a very small portion from which a barn was removed about twenty-two years since, and from which portion the following calculations were made:

No. of hills on the acre	22,440
Average No. of stalks in each hill, 73, or on the acre	1,638,120
Average No. of kernels in each head, 77, or on the acre	126,135,240
Average No. of kernels to the bushel	848,560

"No. of bushels to the acre, according to the above calculations as ascertained by counting stalks and kernels, one hundred and forty-eight and about five-eighths.

"Planting wheat on poor land is like planting other crops upon poor land: it will not pay. Make your fields rich, and in a good season I will warrant any man one hundred and fifty bushels of most excellent wheat upon one acre of land, if cultivated as above. On the rich bottom lands of the Scioto, Muskingum and the Miamis of Ohio, and also on the river bottoms and prairies of the great west, winter wheat can not be grown to any extent by being sown broadcast, on account of blight or mildew, and by heaving out by frosts of winter. By planting in rows and hills it would naturally be exposed to the action of the sun and winds, and thereby prevent blight or mildew, and by covering with the hoe, prevent heaving out by frosts, thereby securing a good crop.

CHARCOAL A DRESSING FOR WHEAT.

"I tried another experiment in 1860. My lands are coarse or loose gravel of rather poor quality. I sowed an acre of winter wheat (the Blue stem) preparing my ground as follows:

The field was sown with barley in the Spring previous; yield small (18 bushels per acre). I turned in the stubble the last week in August, harrowed it over, then took about eighteen bushels charcoal crushed fine, and top-dressed a strip through the middle of the acre over about one-third of its length; I then sowed on my wheat broadcast and harrowed it over twice. The result was, the heads when ripe were at least twice as long as where no coal was put on. I harvested all together; the yield was forty-three bushels. I think by applying about fifty bushels of coal to the acre as a top-dressing, made fine by grinding in a common bark mill, it would increase the yield at least four hundred per cent., if the soil is poor.

BURNED CLAY AND ASHES.

"In the fall of 1860 I used about one hundred bushels of burned clay, taken from a fallow where timber had been uprooted several years by heavy winds. The soil on which the timber grew was burned together with the old roots and clay entwined, and perhaps some muck; the whole, ashes, clay and muck, after being burned as above, was hauled off in a wagon and put upon the wheat field as a top-dressing, and harrowed in with the wheat. The land was poor quality gravel; the yield was about five hundred per cent. over the remainder of the field where no clay was put. I think there is no fertilizer ahead of this as a top-dresser."

Torrefied Earth, or Burned Clay, is extensively used in some parts of England and Ireland. The heavy, clayey soil becomes greatly amended mechanically, and besides, the clay thus heated absorbs ammonia and holds it, and gives up readily other valuable ingredients which would otherwise be firmly held, and therefore unavailable.

Rye.

There is no better test of the hardiness and value of rye, than the fact that it has a place upon the most exhausted farms. It bears abuse and neglect better than almost any other grain. The facility with which it can be raised has been nearly fatal to much good land in the north. When wheat could no longer be grown with profit, rye took its place, and as it would yield remunerative crops without manure, land was sowed to this grain with no other rotation than grass, until it would not pay for plowing. It is still a common practice, notwithstanding the inroad new ideas have made, to turn up old pastures and exhausted meadows and sow with rye without any manure. A crop of ten or fifteen bushels will about pay expenses, and many farmers are satisfied with this scanty yield.

A rich hazel mold, well drained, or naturally dry, is the best soil for rye. If it is light, it should have manure. The great luxuriance of this plant upon newly cleared forest land shows that it delights in a soil well stocked with food. It is a good plan to manure broad-cast, and plow in ten or twelve loads of stable manure or of good compost, but still more important to apply a part of the manure, which should be well rotted compost, to the surface, and harrow in with the seed. One of the best dressings for this crop is 'fish pie,' or compost made in June, and applied in September at the time of sowing. This is a favorite manure along the sea-board, in the rye growing districts. The fish are sometimes applied broad-cast to the green sward several weeks or even months before the land is plowed; but this is a very wasteful practice. No better rye is raised in the world than along the shores of Long Island Sound, with this fertilizer. A yield of forty bushels to the acre, under favorable circumstances, is sometimes realized.

It is very much better to use some manure and get twenty five to thirty bushels to the acre, than to sow on sward or stubble, and get ten without any manure. As rye will sprout at a very low temperature it may be sown late, but does much better to be put in in September. If it grows too luxuriantly, it may be fed off in October with calves or young stock. Sheep are apt to feed too close and pull up the roots. Late feeding is injurious, as it would leave the roots altogether too bare for winter.

The true place for rye is not as a crop to filch from the soil its last elements of fertility, but to come in, in a judicious rotation of five or six years. A good farmer ought to be ashamed to raise less than twenty five bushels to the acre, when, with a little more manure, he may just as well get thirty five. Rye should have its place in the rotation until we have brought up our farms to a condition where they will grow wheat, an event that is sure to follow tile-draining, and a higher state of fertility.

We have not as many varieties of rye as of wheat, and not much is generally known except of the common winter grain. Spring rye is very little grown, most farmers preferring Spring wheat or barley, where they have land in condition for any Spring grain. The white rye raised extensively in New-Jersey is a fair, handsome article, about the color of red wheat, large and prolific. It is not yet very widely distributed, but enough is already known of its productiveness, hardiness, and other good qualities to determine its value. There is a fine field here for the enterprise of some wide awake farmer. This grain is as susceptible of improvement as wheat or barley, and a few years of careful cultivation from select seed would give us improved varieties unquestionably much better than any thing we now have.

This grain is highly prized in all the districts where wheat is not raised. Chemical analysis shows that it is but a little below wheat in nutritive value, and this estimate is confirmed by the analysis of the stomach. Well bolted, it makes excellent bread, the best substitute we have for the wheaten loaf, and by some preferred to that standard article. As a variety, it is highly relished at most tables, if not in the loaf, at least in short-cakes and biscuits. The bran is indispensable in the loaf of brown bread, which is a good old institution handed down from our grandmothers, and which we trust will be perpetuated to the latest day.

The straw, always the most economical bedding for stables, has of late years become of considerable value in the arts, selling as high as fifteen dollars a ton. But this of course only benefits the farmers in the limited districts near the factories. In the packing of winter fruit, it is thought indispensable by some of our best fruit growers. Rye has always a good home market, is one of the surest crops, and deserves more careful culture and selection of varieties

Notes on the Run—From Albany to Manassas.

MR. EDITOR:—Having recently made a hasty trip from Albany to Manassas, I have thought that a few notes agricultural and horticultural, then jotted down, might interest your readers.

It was the morning of the 17th of June, bright and clear. On the night of the 15th there had been a hard frost, nipping off corn, beans, tomatoes and such like tender plants, injuring them so badly that in many places they needed to be replanted. Here and there a few half-ripe strawberries could be seen—only a few. And the children and the birds had found a few pale red cherries. A few of the earliest roses were beginning to open; all the others were only in bud. So of the azalea, rhododendron and kalmia. On reaching New-York city, it was plain that we had got into a warmer climate. Strawberries and early cherries appeared in market plentifully; here, too, were green peas, snap-beans and early beets. Bouquets, in which roses of all sorts figured in full bloom, were sold about the streets. No signs of recent frost.

Visited Central Park.—What splendid carriage-drives and walks! broad, hard, smooth and clean. And these patches of lawn, those sunny slopes and knolls, and yonder broad parade ground; these bridges; the lake or skating-pond, with the swans and their young broods; the cave and the ramble; the high points for observation of the city and surrounding country—could any thing be finer? The spot known as "the Ramble," is one of the most interesting features of the Park, its original wildness, of rocks, ravines, springs and brooks, of trees and vines and plants, remaining as it was, to a considerable extent, though modified and improved by walks, rustic bridges, canopied seats, boat-houses on the lake, and by the planting of numberless curious trees, shrubs and vines. One needs to be careful amid these winding footpaths, or he will lose his way; but the temptation is very great to wander on and on and on, for at every turn he finds something new to attract him. I think, Sir, you had better advise your readers to visit Central Park, rather than Barnum's Museum. [Our *readers* need no such advice; some will even go there before they will come to the office of the *Agriculturist*.—ED.]

But why so many dead and half dead young trees? They are those which have been recently planted, and which have dried up in the recent drouth. But why were they not watered and mulched? You have salt marsh grass in abundance and handy, and the water which you sprinkle so bountifully on those carriage roads might some of it have been well applied to these trees. With money, men and material provided so liberally, it is not creditable to the planters that so many rare trees should die on their hands.

And why crowd your trees so closely together? Here are Austrian, Scotch and American White Pines and Spruces huddled within four feet of each other, and within the same distance from the walks. Of course, within a few years, these trees will crowd each other and become one-sided, and their lower branches will over-spread the walks and roads. It will then be necessary to cut down half of the number, and to lop off all the lower branches of those which remain, leaving the trees maimed and imperfect. Why not foresee these difficulties at the outset, and plant accordingly? I fancy the response, "Well, Sir, you are right, but public sentiment seemed to require us to plant for present effect and to let the future take care of itself." But faultfinding is not my mood; and indeed there is little in these noble grounds to criticise. Can any body find fault with this Terrace, and the Promenade or "Mall" leading to it? When completed, the architectural effect will be truly grand and imposing. There is nothing like it on this side of the Atlantic [or on the other.—ED.] Drive around to the Deer Park. Here is a section of ground—half an acre, perhaps—surrounded by a wire fence or screen, painted the color of grass, and hence almost invisible. It is so high that the nimblest deer can not over-leap it, so strong that they can not push it over, and yet so light and inconspicuous that at a short distance it would hardly be noticed. Let me commend such a fence to amateurs who would like the luxury of a few deer in their grounds.

But I have not time to speak of everything, and only make note further of the old and new Reservoirs, to furnish water for the many thousand lips of the great city; of the eight streets almost subterranean, crossing the Park, without interrupting its privacy; of the Arboretum, etc., etc. Suffice it to say that no one should visit New-York without making at least a flying trip to Central Park.

* * * Swift we fly over the rails from New-York to Philadelphia, through towns and villages; now we pass handsome country-seats, fertile farms, and then, though rarely, through wooded scenes, where we see laurels, azaleas and rhododendrons in a blaze of bloom, and oh! how beautiful! The Red Cedar abounds on every side, and takes a great variety of forms; now upright and dense, now loose and spreading, and then with branches almost horizontal, with the foliage on the upper side resembling pile of velvet. Near Trenton, the Weeping Willow seems to be in perfection, many specimens being as large and vigorous as full grown oaks. Here, the corn is six inches high; we left it at home just peeping out of the ground, and much of it nipped by the frost. Around Philadelphia, the farmers are making hay, and the wheat crop is turning yellow. Peaches are fully two thirds grown, and promise a large yield.

Much of the land between Baltimore and Washington looks thin and poor; yet here and there are farms which show what good cultivation can do. Probably the railroad runs through much of the poorest land. Yonder are women at work in the fields. Can not, at this distance, discern the color of their skin; they must at least be well sunburnt. All along between New-York and Baltimore the native Juniper is seen by the roadside. Now and then, it is browned up in spots, where its sides have been exposed to harsh winds. Then let not our more northern planters pronounce it too tender, because it sometimes has this appearance.

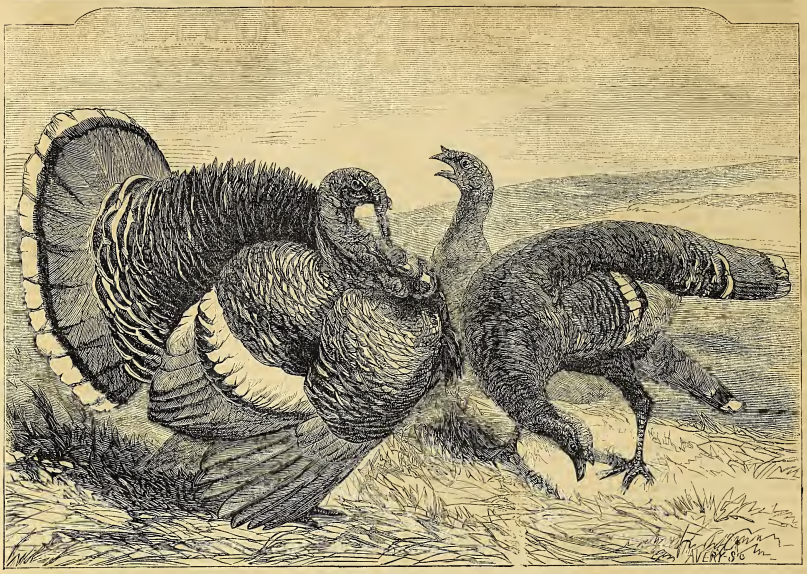
And this is Washington—less a "city of magnificent distances," than when I visited it, twenty-five years ago. The great gaps between the different blocks have been pretty well built up, and its 70,000 inhabitants make the streets quite lively. At present, the nation, as here represented, has beaten its plowshares into swords, and its pruning-hooks into spears. Nearly every other man on the sidewalk is a soldier; cavalry, artillery, and long trains of military wagons continually ramble through the streets; and forts and camps bristle on every hillside. Nobody to-day to the market. A little of everything for sale, here. Meats of all kinds, and suspenders and cambric needles; fish and jack-knives, candy and tin-ware. Strawberries abundant, large and fine, chiefly Wilsons, Alice Mauds and Early Scarlets. Longworth's Prolific, Iowa and Hovey, at a few stands.

Visited the grounds of the Smithsonian Institute, and of the Capitol, White House and President Square. In the first, was surprised to see that the grass around the edifice had been allowed to grow unshorn until now, the 23d of June, when it was being cut for hay! It would seem that an Institution so largely endowed as this, might afford to keep a portion of its grounds under the scythe and roller, at least those immediately adjoining the grand pile. I looked around for the marble vase erected here in memory of Downing, who laid out this place, but was obliged to wade through a large expause of *uncut* hay to view it. A beautiful work of art it is, and worth taking some trouble to see. Here, and in President Square, are some fine specimens of the rarer evergreens. The Deodar cedar, in certain exposures, loses its leader, and makes only a large, spreading mass of branches, but elsewhere, it does well, and becomes exceedingly beautiful. Downing has here set it often in proximity to the Hemlock, and it endures the comparisou bravely, which is saying much. It resembles the Hemlock somewhat in the style of its foliage, but is of a greyish green, and more feathery and flowing. The Hemlock is the richer and grander of the two. The European Silver Fir thrives well here, and has a very dignified, architectural regularity. Very noticeable, too, are the Deciduous Cypress, and the Chinese and Golden Arbor Vitæ, and the Yews, Irish, English and Golden. This last is often set over against a group of darker conifers with fine effect. The same thing is seen in the juxtaposition of the deciduous cypress of soft, yellowish green and delicately cut leaves, with the broad and dark foliage of the Catalpa. And why are there no large trees immediately in front of this majestic structure, and only a few groups of shrubbery set near the foundation walls? Plainly is seen the design of Downing thereby to enhance the loftiness and grandeur of the edifice.

The grounds around the White House, and in President Square, opposite, are maintained in the highest order of keeping. The grading is excellent; the walks are broad, smooth and clean; the grass smoothly shaven and rolled; the trees, in nearly every case, chosen specimens, and these well-cared for. *Some* cunning hand has given admirable shape to these trees: we would like to know his name, that we might praise him. The view from the south window of the famous East Room of the Presidential mansion, is seldom surpassed. Beneath, in the immediate foreground, is the flower-garden, and the lawn with its fountain and flag-staff, the whole skirted with trees. Through a broad opening in front through the trees, spreads out a large meadow with cattle grazing, or reposing in the shade. Beyond this rises the Washington monument, and further on lies the Potomac, winding its way down to Alexandria, until the view is lost in the blue-hills of old Virginia—entering, bleeding old Virginia.

The favorite street trees in Washington, are the Abele and Silver Maple. Now and then a Button-Ball, or Ailanthus is seen, but nine-tenths of the trees are those first named, and their quality is only second-rate. There does not seem to be much system in planting. A city of this age and size ought, by this time, to show fine avenues of large trees. In such a warm climate, they are almost indispensable to comfort.

On board the steamboat for Alexandria. And do these green-hills show any signs of the prevailing war? Only that, here and there on the crests there are forts, each crowned with the "Stars and Stripes," and that a wide strip of forest has been cut away between each fortification and the river. Having procured "a Pass" from the Provost Marshal, (a privilege seldom granted to civilians) we enter the cars for Manassas Junction. Our fellow passengers are nearly all soldiers returning to camp from furloughs. Losing sight of the earthworks around Alexandria, we pass at every road crossing, bridge, or sudden turn of the railway, squads of soldiers, stationed here to guard the track and the telegraph. But where are the farmers and gardeners along this railroad? Only here and there do we see any growing crop. The fences have long ago been burned by roving bands of armed men to light their camp-fires. Now the train rumbles across "Bull Run," whose waters, several miles northward, were once reddened with human blood. And now, we see within four miles of "the Junction." Not a fence or cultivated field or garden is to be seen. The trees have mostly been cut down for fuel and to build the huts occupied by the Confederate army, last Winter. And here are the huts, large villages of them, scattered over the rolling table lands. Arrived at the "Junction." What a scene! It reminds one somewhat of State Agricultural Fair, on its last day. Rough board shanties of sutlers, with flaming signs; tents innumerable scattered over the plain; soldiers, negroes and women running to and fro; horses neighing and prancing; mules braying; locomotives screeching, and a general scene of confusion, noise and dirt. And yonder are the fortifications which kept the Federal army so long at bay. Between these numerous rifle-pits and breast-works, and all over the plain, grass and weeds are now growing luxuriantly. Not a feuce to be seen as far as the eye can reach, nor a cultivated field, orchard or garden. All is one wide scene of desolation. Oh! may the time soon come when these lands shall be restored to cultivation. We plucked a few wild flowers as mementos, and returned, glad to lose sight of war's desolations.



THE DOMESTIC TURKEY—(*Meleagris gallopavo.*)

Engraved for the American Agriculturist.

As Americans we must all feel a pride in this grand bird, the largest of gallinaceous fowls, the noblest feathered game of our forests and mountains, yielding the most savory flesh, most easily domesticated, and, in its domesticated state, disseminated and valued over the whole civilized world. America, and particularly the United States, is its home. There is hardly a rocky ravine, a hill, or wood-covered mountain from Maine to California, where the wild turkey-cock has not strutted and swelled, puffed and bowed, doing honor to his dame, or where the hen has not led forth her numerous brood. The cracking rifles, and march of civilization have banished the wild birds but introduced the tame ones—in fact, however, we may say we have domesticated the wild turkey Mixed though our domestic varieties are with those for a long time bred in Europe, still they are constantly crossed with the wild ones of our forests whose eggs are frequently hatched under domestic poultry. Wild turkeys are occasionally shot in all the States of the Union, except, perhaps, in Connecticut and Rhode Island, where, if a flock is ever seen now-a-days, it is very seldom.

The beautiful engraving we present shows the fine contrasts in color of plumage, and the graceful game-like figure of the domestic turkeys. The wild ones are slenderer and better adapted to flight and to running. The flights of the tame birds are often very long; not unfrequently they fly half a mile or more, and the only trouble about keeping them is that they will wander so far, and do such damage in grass and grain fields. This injury is not from what they eat—for though they eat corn of all kinds it is a very good investment, while they eat an immense number of worms and beetles also—but they do injury by trampling and breaking down the crops. The variety of colors in turkeys is very great. The wild ones vary somewhat, but are prevailingly of a dark, bronzy-brown, of great lustre, showing a beautiful metallic, coppery iridescence. Among tame ones we find all colors from pure white to jetty black, and all shades of brown and bronze, ring-streaked and speckled, but in none does the lustre compare with that of the wild. Occasionally these birds grow to a very large size, the cocks weighing 35 to 40 pounds live weight. They continue growing 4 or 5 years, and can hardly be said to be fully mature before they are 3 years of age; birds therefore, both cock and hen, which are used to produce breeders, should be three years old.

Plant the Bulbs Early

When the Dutch Bulbs can be obtained in September, it is well to plant them at once. An earlier and a finer bloom will be obtained than when left until just before the ground freezes up for the Winter, though they may be planted as late as December. There need be no delay with those lifted and dried last Spring. A small collection may be planted with the varieties interspersed, but where the assortment is large it is best to set the tulips by themselves, the hyacinths in another bed, with a separate place for the crocusses, crown imperials, etc. Some florists carry it still further, and set each *color* of a variety separate from the others, and even place the tall sorts of each color apart from the dwarfs of the same variety. The books, too, are so prolix in their directions, how deep to excavate the soil, what proportions of sand, muck, leaf-mold, cow manure, etc., should be used, that many persons who otherwise would grow these flowers, are deterred from so doing. Did they know that any good garden soil will answer, and that it is as easy to plant a bulb as to set out an onion, they would no longer hesitate.

Most of these bulbs are imported from Holland, where they mature better than with us, and on this account are called Dutch, though they originated in different parts of the world. In selecting bulbs from the importer, choose those of a solid, firm character. By all means discard those which are starting into growth, for planted thus early, they will continue to grow, and be injured by the frosts of Winter. Let them be bright and hard, and the further removed from a growing state the better. If one has a choice of soils, let him select a good loam, somewhat gravelly or sandy, and if muck or peat and cow manure can be added to enrich it, all the better. Fork or spade it up lightly. Oval or round beds are very pretty. Set a few of the taller growing Crown Imperials in the center, three to four inches deep and one foot apart—white and Japan lilies may be interspersed among them; surround these with the late growing Tulips, followed by the dwarf sorts. Set six to ten inches apart, according to their hight, and cover with two inches of soil. Hyacinths may follow next in another circle or two

eight inches apart, covering to the same depth as tulips. Complete the bed with crocusses and snowdrops alternated in masses, the former two inches and the latter three inches deep, and both 2 to 4 inches apart, or in rows 4 or 5 inches apart. Upon the approach of Winter, cover with coarse stable litter, to be raked off in early Spring. In the season of blooming, from the first of April to the middle of June, the gay colors, varied forms and odors, will well repay the careful cultivator.

Newer Annuals.

The double Zinnia, now two years out, is a desirable thing. It was loudly trumpeted in England, before it was imported here. Dr. Lindley said it was "not a whit less interesting than a double Dahlia." Few will agree with him there. Certainly, we should not, judging from those raised last year in our own garden. They were double and semi-double, but were less brilliant in color than the old single sorts. The several new sorts of Japan Pinks, single and double, are really valuable acquisitions. Flowers larger than the old Chinese pinks, and of bright crimson, striped, mottled, etc., etc. The seeds are to be had now of all florists. If first started in a pot or box of earth in the house in April, they will flower the first season.

A Good Thing for the Flower Garden.

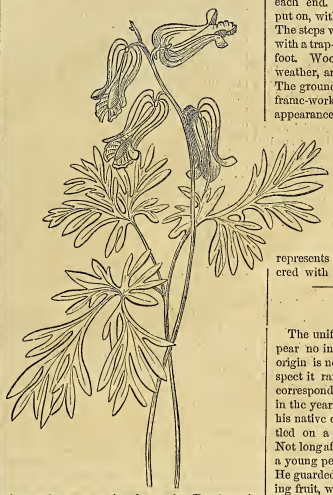
The present passion for bedding-plants is causing a good many plants, formerly confined to glass-houses, to be tried in the open air, from spring frost to fall frost. Among these we have seen the *Calceolaria*, and *Gaillardia picta*, planted out in the open ground this Summer, and the *Mimulus*, and the Dusty Miller Geranium, and even the Egyptian Lily in moist, shady places.

In our own garden, we have tried the Brugmansias for two years, and find them exceeding our expectations. This is the old family of *Datura*, changed to *Brugmansia*. Any one can raise the plants from cuttings, which strike quite readily. For immediate and effective show, the main reliance must be on large plants. Having such an one, select an open spot on the lawn, cut out a circular bed, three or four feet in diameter, and enrich it with old manure. Set the plant from its pot into the center, and tie to a firm stake. By mid-summer, it will make a grand sight, and will give pleasure by its show of an abundance of blossoms all summer long.

There are several sorts, more or less desirable. *Brugmansia Knightii* is our favorite. The flowers are pure white, tubular, often six or eight inches long, and delicately fragrant. B. *sanguinea* has flowers white and green. B. *floribunda* is orange-colored. As soon as frosts come, re-pot the plants, cut back the tops considerably, and set away in a cool corner of the greenhouse, or in the cellar. Treat them in all respects like the common scarlet geranium.

Squirrel Corn (*Dicentra Canadensis*).

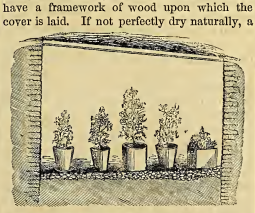
This beautiful little flower of early Summer is one which, with care to reproduce in the garden the conditions of the rich woodland in which it rejoices, namely: some shade, a vegetable mold, and a moderate degree of moisture, though not wetness, grows and blossoms beautifully, giving a freshness and interest to some quiet nook which is very attractive. The botanical name is *Dicentra Canadensis*, and this indicates its hardiness. It is a low growing perennial, throwing out underground stems which form tubers about as big as small grains of corn, from which the English name is derived. These tubers are at this season ripe and may be taken up and removed to the garden. The flowers are greenish white, with a tinge of red, and fragrant. This form is quite peculiar, as represented in



the cut, but not so singular as the Dutchman's breeches, (*Dicentra cucullaria*,) which is a closely allied flower that blooms a little earlier.

Flower Pits.

In response to several inquiries, we introduce the above cut to illustrate the method of constructing a pit for keeping flowers and tender plants during Winter. These pits should be dug in dry soil, and may be stoned or bricked up, or have a framework of wood upon which the cover is laid. If not perfectly dry naturally, a



drain should be constructed to carry off water. It is best to use green-house sashes to cover the pit, but not absolutely necessary. A correspondent in a former volume described with sufficient minuteness a pit which worked well, and we reprint it here: "A pit was dug twelve feet long, six feet wide, and six feet deep. The digging occupied one man nearly three days. Locust posts were driven at each corner, and two others on one side for the door, and a lining of spruce boards an inch thick nailed on the inside of the posts, leaving a space of three to four inches between the boards and the earth. This space was closely packed with coal dust, fine ashes, and other similar materials at hand. The bottom was paved with rough stones. The posts were kept firmly in their places by a brace at each end. A common frame-work was then put on, with three sashes; a door fitted closely. The steps were outside of the door, and enclosed with a trap-door. The sashes sloped about one foot. Wooden shutters were put on in severe weather, and covered with a layer of salt hay. The ground around was neatly sodded, and the frame-work painted, making a very good appearance. The carpenter's bill, including outside shutters, was $58, making the entire cost somewhat less than $65. It held about 125 medium-sized pots; and every plant kept in it the past Winter is untouched by frost. It was tightly closed when the severe weather came on, and not opened until the mild days in February." The preceding engraving represents a stone or brick walled pit covered with sashes and a mat of straw above.

The Seckel Pear.

The uniform and universal excellence of this pear no intelligent person will doubt, but its origin is not so fairly undisputed. In this respect it ranks with the Delaware grape. A correspondent of a Minnesota paper says that in the year 1761, a Frenchman, banished from his native country, came to America, and settled on a point of land below Philadelphia. Not long after he had built his cabin, he observed a young pear tree growing up near his door. He guarded it until it came to the age for bearing fruit, when he was rejoiced to find the product of superior quality. He carried a few to market, where they found ready purchasers. And so on for ten or fifteen years his seedling pear tree brought him a handsome little income. The Frenchman kept the whereabouts of the tree a secret as long as possible, and when it was discovered, he forbade cions to be taken from it. As he always kept an old *sickle* hanging on a limb of the tree, it came to be called the Sickle-tree, and hence the Seckel. In the year 1821, he died, and bequeathed his little home and favorite tree to Stephen Girard, by whom grafts were soon distributed.

That's one story. Mr. Downing tells another, to wit: that the seedling was raised by a cattle dealer, near Philadelphia, known as "Dutch Jacob"; that he afterwards sold the land on which it stood to a Mr. Seckel, who introduced the fruit to public notice. Afterwards, the farm and tree became the property of Mr. Girard. The original tree is believed to be still alive.

Manure for Pear Trees.

Undoubtedly, there are some soils which need very little manure. Such, especially, are the deep, virgin lands of our meadows, where the deposits from the overflow of neighboring streams have been accumulating for centuries. But such lands are not everywhere to be found. There are large districts in which the soil is comparatively light, and which have been exhausted by long cropping. Let no one think of growing pears here without manure. This tree is a gross feeder, and soon consumes the elements of nutrition within its reach. Both the

size and color, and the flavor of the fruit are determined by the richness of the soil.

What manure shall we apply? Barn-yard dung, simple and unmixed, might be safely used in moderate quantities; but doubtless, a mixture of this, with rotten leaves, sods, ashes, bones, night-soil, street-scrapings and the like, would be better. Let these lie in a heap a few months, and then shovel them together, and the compost may well be labelled, "Pear-tree specific." Spread this dressing over the roots every Fall, and work it into the soil in the Spring. Of course, the weeds and grass are to be kept down; for about as much good will come from this tillage as from the manure.

The above directions apply with special force to dwarf-pears. The quince-root, being small, can not throw out its rootlets far and wide in search of food, when the soil near the trunk is exhausted. The food must be brought to it, regularly, and enough of it, too, to supply its constant wants. Follow this up, with systematic pruning, and the labor will be well repaid.

Water in Ornamental Gardening.

Persons living on the sea-board, or on the shores of our lakes and rivers, need little said to them in reference to our subject. They know well how important a feature water is in their scenery. They have become so attached to it, that it seems they could hardly live without it. A friend of ours who once lived on the sea coast, but now resides in an inland village, often goes down at evening to the shore of a fish-pond, that the motion of the little wavelets may remind him of the rolling sea! When persons who have long resided near the water-side come to travel through scenery otherwise beautiful, but lacking this one feature, they exclaim: It's all very well, but oh! where is the water!

Fish Ponds.—It is our present purpose to speak of water on a smaller scale—of the uses that can be made of it in lawns and gardens, and retired portions of one's premises. Few things are pleasanter than a simple stream or pond of clear water, partly overhung by trees and vines, and filled with fish. If our miniature lake is large enough for a boat, this will add much to its beauty and enjoyableness.

There are many places now destitute of this attraction, which might possess it. Take, for instance, a valley with a small stream running through it. Throw a dam across the lower end of the valley. Make it of stones, and firm enough to resist the pressure of any freshet. Have a waste-way large enough to carry off all superfluous water, and to drain the pond whenever necessary. Care should be taken that the sides of the pond be irregular and flowing, not square, or exactly round. From no point should the spectator be able to see the whole body of water at once. The stream should be large enough and sufficiently constant, to afford a steady flow of water in and out; else we shall have for our pains nothing better than a morass or frog-pond. At the outlet, the stones of the dam should be laid in a rough, picturesque manner, so as to form a musical cascade.

——The dale
With woods o'erhung, and shagg'd with mossy rocks,
Whence on each hand the gushing waters play,
And down the rough cascade, white, dashing fall,
Or gleam in lengthen'd vista through the trees.

Management of a Brook.—But a stream of water may be enjoyed in a different way, and on a still smaller scale. It may not be advisable generally to introduce a brook into a highly dressed lawn or pasture; we should rather say, bring it in at some side corner, some shaded nook, where there is some little air of natural rusticity. Here, lighten the native wildness by bringing in bowlders and mossy logs and stumps; plant forest trees, and shrubs and vines and plants from the woods, until the place is completely embowered, and has much the appearance of a little forest. Make the sides and bottom of the stream jagged with rocks, and plant trailing vines and various water-loving plants to overhang it. Perhaps a cascade or miniature waterfall can be constructed, whose silvery music will always be pleasant. One of the most agreeable incidents in a recent journey of the writer was a visit to a friend's cottage, near which was a scene like what we have above hinted at. And we now refer to it the more earnestly, because we *know* it is a practicable thing, and a cheap and simple source of enjoyment. Of the children's water-wheel, and their fairies' grotto, and their hut, we can not now speak more particularly, though we shall not soon forget them. Children always enjoy water, and in making water-wheels, boat building, wading, bathing, and skating in Winter, the brook and the pond cultivate mechanical ingenuity, and afford them amusement and exercise.

Fountains and Jets d'eau are more artificial and costly, and properly belong to the highly dressed parts of the ground near the house. The water to supply them is commonly brought in through pipes underground from some elevated reservoir. When the water is abundant, and the entire fixtures are well made, and of a pure classic design, the effect is very good. The silvery plash of the water in its marble basin is very soothing in a hot summer's day. When the supply of water is quite small, instead of attempting a jet, a better way is to have simply a dripping fountain. "A basin of any material," says a judicious author, "from the coarsest common stone to white marble, with a block of the same in the center, supporting a graceful vase, in which the water boils up and falls gently over the rim into the basin, will give more pleasure both to the eye and the ear than any other application of the same amount of water." And again: "A small clear stream may be made to break from an apparently natural fissure in a mass of rock-work, and flow down its side into a pebbly basin below; a graceful nymph may pour water from her urn; or many other beautiful uses may be made of even a small quantity of water, always provided it be of crystal purity. But by all means avoid making the likeness of bird, beast, or fish, throwing water from its mouth: in spite of its frequent use in celebrated fountains, this is too much like one of the most disgusting ills that flesh is subject to, to be anything but revolting to good taste."

Water-Pipes, etc.—For bringing in water from distant reservoirs, iron and lead pipes are unquestionably the most durable; cement pipes, well laid, are good, but logs of the right material, well bored and properly laid, will last many years. We have lately examined a set of log-pipes, a half mile long, which run down one hill and up another, through which a stream of water has flowed fifteen years with only two short interruptions. And we could not see why they might not last for as many years to come. Of the hydraulic ram, the wind-mill, and other contrivances for introducing water, we have not the space now to speak. This whole subject is an important and interesting one, and we commend it to the thoughts of our readers.

Cherry and Plum Trees.

In the partial failure of these trees in many portions of the country, there has been a strong tendency to abandon their cultivation entirely. A very unwise proceeding. The panic, we hope, has already spent itself, and trust that men will again return to their reason.

CHERRY TREES.

In reference to the bursting of the bark, and the dying out of cherry-trees from the cold of Winter or from other causes, these evils are not absolutely beyond control. They should be charged, partly at least, to the practice of planting the trees in too rich and deep soil. In such situations, they make a very rapid growth, the wood is soft and watery, and when winter comes, the tender tissues are frozen and rent asunder. Here is an item from our own experience, illustrative of the above: Ten years ago, we bought eight young trees of the finest improved varieties, among which were the May Duke, White Ox Heart, Black Eagle, Black Tartarian, Yellow Spanish, and Downer's Late Red. Four of these were set in a rather low and very rich and deep soil; and four of them on higher land, and where the soil was light and shallow. Indeed, where the last four stood, the top soil had been plowed and scraped off a foot or more, and carried into the lower ground where the first four stood. Yet the two lots were not more than fifty feet apart, the only difference being in the character of the soil, and in about fifteen feet of altitude. Now, mark their history. The first lot grew vigorously for two or three years, but soon began to show ruptures in their limbs and trunks. After a while, two of them died outright in a single winter, and the others are now about half-dead. They bear a little fruit—only a little—on the few surviving limbs. The second lot grew quite slowly. They are now all alive, have only a few spots of rupture, and bear good crops almost every year. This year, they have done admirably. Such experience and observation lead us to think that if cherry-trees were treated to a little more neglect, giving them rather poor soil, setting them on exposed sites where they would grow slowly, and ripen their wood earlier, they would succeed better than they now generally do. Is not this worth a fair trial?

THE PLUM TREE.

This is a comparative failure in many regions, owing to the black knot, or the ravages of the curculio. Yet in other places, and under a certain course of management, it succeeds tolerably well. It is a plain case that the plum will not thrive and be fruitful, if neglected.

Whether the knot is caused by an insect puncturing the bark, or is a fungus arising from a diseased constitution of the tree, we will not now stop to consider. Experience shows that the only sure way to manage it is to cut it out, and cut it out again, whenever it appears. Cut down to the last vestige of it, and then cover the wound with shellac varnish or grafting wax. Begin with the tree early in the season, cut out every wart on the large limbs, and cut off every small limb that is affected, and burn it. If it be an insect that causes the knot, he will thus be put out of the way for at least one year. Do this for several years, and persuade the neighbors and the nurserymen to do it; and the knot will gradually disappear, or what little remains will do no serious injury.

As to the curculio, we have heretofore discussed his case quite at length, and now will only repeat that some growers succeed well by paying

the ground beneath their trees, so as to prevent the insect burrowing in the ground in the Fall; others cover the ground with a coat of mortar two inches thick; others plant their trees around the kitchen door where the constant treading of the ground, the frequent jarring of the tree, and the various domestic odors and noises become offensive to the curculios; while others set them in the hog and poultry yard, where the rooting and scratching answer the same purpose; and others still are very successful with the wash recommended on page 177. Let any of these methods be tried, as most convenient.

We have long observed that plum-trees succeed better in city back-yards, than in country orchards; and plainly, because of the constant passing to and fro, the stamping of the ground, or the paving stones, or such like reasons. The Grand Turk don't like to be so much annoyed by the presence of men, women, children, and chickens; he don't like such hard floors, don't like kitchen odors and washes, and so he leaves in disgust.

We now and then hear of "secret" and "patent" methods for expelling the curculio, but after all prefer to fall back on those before mentioned, or, better still, on the practice of jarring the trees when the curculio is on them, and gathering up the fallen insects into sheets and burning them. *

Weeping Trees.

We are not insensible to the beauty of natural upright trees; and, most of all, to the noble denizens of our native woods. Nor are we ignorant of the fact that some of the imported pendulous trees are rather tender in our northern climate, and that others, after making handsome progress for a few years, at length out-grow the stock on which they are budded or grafted, and break off, or get into other bad conditions. But this is not so with many.

Beautiful and indispensable as may be the favorites of our forests, why need we be confined to them? Some persons would plant only elms; with others, the maple is the favorite; with others, evergreens; and with others, weeping trees. Let us avoid either extreme. Nature gives us spiry-topped trees, like the Larch, Lombardy poplar, and many of the conifers; round-headed trees, such as the linden, ash, maple and chestnut; pendulous trees, such as the willow, white elm, etc. Taking a hint from nature, gardeners have sought out and introduced a number of other drooping trees, so that now, in addition to two or three new willows, we have weeping oaks, poplars, birch, beech, larch, ash, laburnum, sophora, thorn and others. Why not use all sorts of trees, mingling them as nature does, either with little regard to laws of "effect," (yet generally accomplishing that end), or arranging them artistically, to reach special results?

Just how and where to place them, is not so easy a matter to decide; yet a few things are plain. Drooping trees of fine form may well stand conspicuously upon a lawn, if not more than one or two be in view at a time. They answer a fine purpose when set near the outskirts of a group of round-headed trees, as if there by accident. In such places, they show the peculiar style of their branches with marked effect. The margins of streams or lakes are also appropriate places for them. For cemeteries, they are very suitable. They make a partial substitute there, for the beautiful weeping willow, which is too tender at the far north. They have, too, this special fitness for burial lots, viz.: they do not often become too large for the space in which they are set, a thing which can seldom be said of the trees commonly planted in cemeteries. This thing, at least, is certain, that these trees wherever planted attract much attention. They suggest ideas of art, of something peculiar and different from the ordinary ways of nature.

In our experience, the following are among the hardiest and best of these trees, viz.: the old European weeping Ash, weeping Mountain Ash, weeping Linden, weeping Scampston and Camperdown Elms, weeping Beech, Birch and Oak.

Fruit Growers' Society of Western N. Y.

From the discussions of this Society at its annual summer meeting held in Rochester, June 25th, and reported in full in the *Rural New-Yorker*, we condense the following:

A vote for the best standard pears for family use, gave Bartlett 10, Seckel 9, Flemish Beauty 7, Osband's Summer 6, Sheldon 6, Lawrence 4, Doyenné d'Eté 4. For the same on quince, Seckel 9, Easter Beurre 6, Louise Bonne de Jersey 4, Glout Morceau 4, Beurre d'Anjou 3, Duchesse d'Angouleme 3. For market, on pear stocks, Bartlett 9, Sheldon 5, Lawrence 3. On quince, Duchesse d'Angouleme 10, Louise Bonne de Jersey 9, Seckel 4, and Flemish Beauty 4.

In the discussion of manures and their application, charcoal was very highly spoken of for fruit trees, particularly as an absorbent. An apple orchard, planted by H. T. Brooks, President, six years since, showed a marked difference in favor of the coal left where a charcoal pit was burned two years previous to planting. The trees receiving the benefit of the charcoal were nearly twice the size of the others. In using manure, it was recommended to apply it on the surface. Mr. Downing spreads it on the ground in Autumn, and forks it in in the Spring. Salt was considered a good manure for trees, but care is needed in its application. Too much salt will greatly injure if not kill the trees.

Two remedies had proved effectual for the currant and gooseberry worm. One was to dust the leaves plentifully, at least every other day while the worms lasted, with dry slacked lime. A few days' neglect would ruin the crop. The other remedy, equally as effective, was strong suds, made of soft soap or whale-oil soap, one pound of soap to four gallons of water, applied every other day.

For the American Agriculturist.

Strawberry Culture at the West.

A VISIT TO THE KNOX FRUIT FARM.

As an amateur in strawberry culture, I made a journey of nearly 500 miles and back to visit the fruit farm of Mr. Knox at Pittsburgh, in the midst of the strawberry season the present year. I can truly say that from what I there saw, I felt amply repaid for my trouble. I have examined both large and small plantations of fruit in different States, but have never seen either the one or the other, unless in a few private gardens, kept in so fine order as Mr. Knox's fields throughout. I think it safe to presume that no grower in the United States, if in the world, has a larger breadth of soil under strawberry cultivation than Mr. K.

The first object of high gratification, on reaching his grounds, was the fine collection of varieties in the specimen beds, which enabled me to see growing, side by side, and to taste consecutively, the most celebrated kinds, both new and old, of this favorite fruit. To give the full results of my observation in this particular would occupy too much of your space; I must therefore confine my remarks to matters of practical interest to the million.

The first cause of serious disappointment was the sight of a large field of Wilson's Albany plants, only in their second year, and yet not bearing more than half a crop of inferior fruit. Large numbers of the plants seemed to die in the very act of fruiting. I have since seen the same results in this vicinity, and heard of it elsewhere, from which facts I infer, that under the best treatment, the Wilson's Albany can not be relied upon for more than one [or two] year's productive cultivation. Whatever it may occasionally, or for a single season, produce, it is certainly very far eclipsed for home cultivation by that elegant and luscious berry, the Triomphe de Gand—now the favorite both at the East and West.

It must not be supposed that Mr. Knox limits his fruit cultivation to strawberries. Devoting some 50 acres to them, he has also 10 of raspberries, 10 of New-Rochelle blackberries, and large quantities of currants, apples, and peaches. Of late years Mr. Knox has given special attention to grapes, having succeeded beyond his most sanguine expectation with the native varieties, especially Concords and Delawares. He has now 10 acres planted in vineyard, which will soon be increased to 25. His style of trellis is unrivalled either for garden or field culture. It is about seven feet high, built with posts, cross pieces and perpendicular slats, like a picket fence, giving the best possible opportunity for the spread and support of the vine.

EXHIBITION OF STRAWBERRIES IN PITTSBURGH.

I was very fortunate in being present when Mr. Knox made his public strawberry exhibition in the city of Pittsburgh. It was well for the gentlemen who secured honors and prizes at the *Agriculturist Strawberry Show*, that he was not within convenient distance for competition. Without any attempt to display great numbers of varieties, as he could easily have done, Mr. Knox contented himself with exhibiting only the best. Among these, the central object of admiration was a magnificent show of Triomphe de Gands. I was glad to learn that Mr. Knox's expectations with reference to this favorite variety had been more than realized by the product of the present season. Not only was the fruit large, brilliant, and fine flavored, but abundant in quantity, in this latter respect exceeding, as he informed me, any representations he had ever made.

STRAWBERRY SUPPLY OF CHICAGO.

The strawberry season at Pittsburgh is two weeks earlier than at Chicago, although by importation from the south the market here is supplied while "winter lingers in the lap of spring." During the last three years the strawberry supply for this region has increased beyond all accurate estimate. As yet, however, few berries are cultivated in the West besides the Wilson's and other common and coarse varieties. The Triomphe has this year been introduced for the first time, in any considerable quantity. The firm of Kidder & Knox, at Evanston, 12 miles north of this city, have succeeded in growing it in as great perfection as the senior partner at Pittsburgh. Its cultivation here extends our strawberry season from two to three weeks. The parties named will continue to market this variety during the present week, say to the 25th of July.

FRUIT FOR THE WEST.

The present has been a wonderful season for fruit of all kinds in the West. Every variety, both wild and cultivated, has been produced in abundance, and prices have consequently ruled exceedingly low. The results have been discouraging to professional cultivators, but they are clearly advantageous to the public, and will doubtless tend to more general cultivation for home consumption of all the choicer products of the fruit garden.

A HIGH COMPLIMENT.

While on an excursion westward from this city, I fell into conversation with a very intelligent gentleman, who, after an allusion to your paper, emphatically said, "if I were shut up to the taking of but one periodical, that one would be the *American Agriculturist*." Doubtless your list of subscribers enrols many of the same opinion, and has room for more.

Yours truly, Z. Y. X.

Chicago, July 23, 1862.

"FATHER IS COMING HOME!"

(Engraved for the American Agriculturist.)

Evening comes and the labors of the day draw with the day to a close. Quiet reigns; the poultry seek their roosts, the cattle compose themselves for the night; and men whose days are spent in labor, whether of the hands or the brain, gladly leave their work to enjoy their rest. The weariness produced by labor only hightens the pleasures of home; tired hands toss the plump baby into the air, and catch it again as if it were of but a feather's weight—and the back which ached well in the hay field is only invigorated when the boy is lifted upon the shoulders for a turn in the yard. A man has no right to work so hard, with either brains or body, that he can not enjoy the prattle of his children, or a good talk with his wife. It is a waste of life to live without enjoyment, and what enjoyment is comparable with that which parents have in their children, and each other in the quiet of their own homes. A happy home is a near approach to heaven upon earth, and it may as well be enjoyed in the cottage as in the palace—in fact, when we consider how much oftener real happiness dwells in the humble cottage, we give hearty preference to the wealth of the poor man, rather than to the golden store, houses, lands, and perplexing cares of the rich. Happy is he who returns at evening to give joy to so happy a family group as we have presented in the engraving before us. How the expressions of "Welcome home," and of sympathy with the children, mingle in the face of the wife, and how natural and exuberant the joy of the children's greeting! One at least will doubtless assure his readers that while there is always joy to the father in coming home, this feeling is rendered inexpressibly intense upon returning from a sojourn in distant lands.

Farmers, Write.

Yes, write for this or some other paper. Not, if you please, with the intent to make a display of learning or fine writing, but to communicate facts, and notes of experience that will be useful to others. The approaching season of comparative leisure, while results are fresh in mind, is the time to write. Take up any crop or crops of the year, and give us the history. The land was high or low, wet or dry, drained or undrained, poor or rich, old or new. It was plowed in this or that month, and thus or so. The manure was of this or the other kind, and was hauled out at such a time and applied in such a manner. The seed was sowed or planted on a certain day of the month. The growing crop was managed in a certain way, and when ripe was gathered and measured or weighed, and its value estimated, above expenses. Now, give us such simple and minute histories, in plain language, and they will be well worth recording. It is taken for granted, however, that everything is done *accurately*, else all inferences and estimates will amount to nothing. And not only the operations of the field, but notes on stock-breeding and raising, and on the orchard and garden, are worth writing out for publication. As we look abroad over the wide parish of our readers, we feel that there is much useful information here and there, which might profitably be sent to us for dissemination.

A New Foe to the Pine.

We have spoken of insects on the White Pine, looking like mildew, but which, on close inspection, proved small bugs. And now we report a new foe, thus far appearing only on the Scotch Pine. In June last, we observed what seemed little bits of froth, of the size of a walnut, found to contain, in each case, a very active grub, of the size and shape of a large grain of wheat—the forward half was black, the after part brown, shaded with red; he was found chiefly on wood of last year's growth; there was a hole in the bark of the size of a pin, and exuding sap produced the foam. Hand-picking failed on large trees. Whale oil soap and similar reme-

dies may, perhaps, do some good, but we had not the patience to try them. It would be a great calamity to lose this tree and the White pine, or to have them seriously infested with insects. Some of our readers may have something to report as the result of their experience.

How to Collect and Preserve Insects.

In reply to various inquiries the following directions may perhaps be satisfactory and useful:

1. For collecting insects. A net of the thinnest gauze, about a foot in diameter, and two feet in depth, attached to a circle of brass or iron wire (just strong enough to keep its shape when used) and fastened to a light stick about a yard long, a pocket full of wooden pill boxes, some small bottles and old envelopes, are the simplest materials for daily use. The net is to aid the hands in catching insects—the boxes and bottles to secure them, and the envelopes to hold butterflies or dragon flies, which should have the wings folded together and be slipped in so as to prevent injury from fluttering. At home, they can be most readily killed by putting them into tightly corked, wide-mouthed bottles, with a piece of paper soaked in chloroform. A note book in which to jot down localities and plants on which insects are taken, as well as those on which caterpillars feed, is valuable. If these notes are numbered and corresponding numbers attached to the insects, they can easily be referred to. Caterpillars should be kept in separate

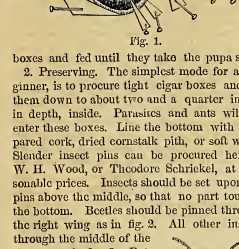


Fig. 1.

boxes and fed until they take the pupa state.

2. Preserving. The simplest mode for a beginner, is to procure tight cigar boxes and cut them down to about two and a quarter inches in depth, inside. Parasites and ants will not enter these boxes. Line the bottom with prepared cork, dried cornstalk pith, or soft wood. Slender insect pins can be procured here of W. H. Wood, or Theodore Schrickel, at reasonable prices. Insects should be set upon the pins above the middle, so that no part touches the bottom. Beetles should be pinned through the right wing as in fig. 2. All other insects through the middle of the thorax as in fig. 3. Butterflies and moths should have their wings expanded soon after they are killed, so that they may dry in that position. Fig. 1. Most other insects can be preserved in alcohol, and remain soft for some time, if it is not convenient to pin them at once. Very small insects may be gummed upon a bit of stiff paper and pinned as in fig. 4. After pinning, those of like families should be arranged together.

Fig. 2.

3. Books. There is no good book for classification, as yet, in this country. Westwood's Introduction to Entomology is the best ever written abroad, but it is expensive, some $12 or $14. The best practical work for the student and farmer in this country is "Harris' Insects Injurious to Vegetation," now republished with many illustrations, price $3 uncolored; $6 colored. Every intelligent farmer should have it. Fitch's "Noxious Insects," is also of great value. The Entomological Society of Philadelphia have a publication at $1 per year, which is entirely devoted to this subject (E. T. Cresson, Sec'y.), and the Smithsonian Institute is from time to time issuing catalogues of the large number of North American insects already described. Any one who takes up the study in earnest will find plenty to do, and a number of active and energetic persons in different parts of the country engaged in the same pursuit.

Fig. 3.

Fig. 4.

Wine.

The statement is correct that wine is not *made*, but is a natural *product*. It grows, and when the soil, the air, and the sunshine and rain of heaven do not furnish the article, all the art of man is expended in vain in its "manufacture." There are some grapes which will not, even when the vines are so cultivated as to receive the full combination of natural influences mentioned, produce wine; others will. We may call any liquid which is a pleasant beverage "wine," if we will, but that does not make it so. Corn juice will make such a drink. Sorghum juice will, maple sap will, and so will birch sap, rhubarb juice with sugar added, sugar with almost any addition you please, etc., etc. Wine, properly speaking, however, is the fermented juice of the *grape*, which may be preserved in bottles or barrels without injurious change for any desirable length of time. Water and sugar in due proportions added to grape juice before the fermentation takes place, are, we believe, not regarded *legally* as adulterations in European countries, for the addition is innocent and it only puts the buyer's knowledge to test—a tax he pays for not knowing the difference. All other additions are adulterations and illegal. Still, water and sugar are adulterations, unless we admit that the miracle of converting water into wine is constantly performed in our day.

The grapes must hang until perfectly ripe, and the sun allowed to shine on the leaves. Pick in flat baskets, so that none will be bruised. They get no injury if not broken, by lying spread out on sheets in a dry atmosphere a few days, or until a large quantity is gathered. Then pick out every unripe, decayed, hard, or broken berry, handling them cluster by cluster. They are next to be mashed, which is conveniently done in some of the neat little mills made for the purpose, which will not crush the seeds, or by the hands. This mashing operation must be done with care not to crush seeds, and so that every grape is broken. It is sometimes customary to crush with pounders in a barrel, but this is not so thorough or neat a plan, and seeds are often broken. When the grapes are mashed as described, they may be thrown upon a large stout linen cloth in a tub from which the *must* or juice may be drawn off, and then tied up and subjected to *gentle* pressure; afterwards placed upon a cheese press and a *moderate* pressure only applied. The result will be the securing of the sweetest and best part of the juice. The same may be better done upon a regular wine press if one is at hand. This *must* which is thus first secured should be put directly into tight barrels filled within 6 inches of the bung, moved to the cellar and the bung-holes covered with pieces of cloth.

Meanwhile we return to the half-pressed pulp and skins in the press. Transfer this to tubs or barrels; add as much water as you have abstracted juice, and perhaps a little more, together with a pound to a pound and-a-half of sugar to the gallon of the mixture. Cover it close with dampened blankets so that no air can get to it, and suffer it to ferment, for several days, the slower the better, (hence the cooler it is the better, provided fermentation is not checked); occasionally stir it without letting the air have access. After the fermentation has gone on in this way from 4 to 6 days, draw it off into barrels, transferring the pulp to the press, and remove all the *must*. This is barreled in the way already described, only the barrels may be filled a little fuller.

There must always be provided in barrels, kegs or jugs, according to the quantity of wine undergoing fermentation, enough more to fill up all the barrels to the bung when the fermentation is over or nearly so—and this must be subjected to precisely the same influences as that to which it is to be added.

After the first brisk fermentation is over, and an application of the ear to the bung-hole only detects a slight crackling effervescence, the barrels may be filled full and a bung inserted having the same contrivance described and figured in an article on cider—a glass or block tin tube bent and dipping under water in a cup. This effectually shuts off the air while the carbonic acid gas escapes bubbling up through the water.

The more uniform the temperature at which the fermentation of wine proceeds the better the result; a cool cellar which is not wet and musty, but has only that moisture which is natural to cool but well-ventilated places in warm weather, is subject to less variation of temperature than any other place we can control, being cool in Summer and warm in Winter. Frost should not enter it, and a good ventilation should be ever maintained, because where wine is fermenting much carbonic acid gas is set free, which might be fatal to persons entering.

Some time in the early part of Winter it will be noticed the bubbling from the tube in the bung has entirely ceased, even when the barrel is slightly jarred. Then remove the tube and bung it up tight. When warm weather comes (or at the time of the blooming of the vine) another fermentation will come on, which will be of short duration. Some persons leave the wine on the lees (or sediment) to undergo this fermentation, and do not rack it off (transfer it to other barrels) before the second Winter, but it is generally considered best to draw it off into other barrels in February or March the first year. The hole is bored some inches above the bottom of the barrel so that the lees may not be disturbed. The wine should run perfectly clear and limpid, but if it be turbid after transferring, add a few ounces (3 to 5) of Cooper's isinglass dissolved in hot water to a pailful of the wine, and pour this into the barrel, which, when filled, bung up and mix by rolling it about; let it stand perfectly still a few weeks, when it may be examined, and if clear, drawn off into barrels or bottles. Wine left upon the lees undergoes a much more violent Summer fermentation than

otherwise; much of the sugar in the wine will be converted into alcohol and the flavor injured. In racking off into barrels or bottles the wine must be perfectly clear, and to secure a freedom from specks or foreign substances, it is well sometimes to filter it through a flannel, through which it will run very freely. Wine is better if *in a good cellar*, left to "ripen" in the wood, and not bottled before it is two years old.

It seems hardly necessary to reiterate the absolute necessity for perfect cleanliness in all parts of the operations we have described. The vessels, implements, press, mill, etc., must all be clean. The barrels must have been thoroughly washed and fumigated with sulphur *every time* before they are used. Thus alone can sweet, pure wine be produced.

The philosophy of fermentation we can not discuss at the present time, save only to say: The juice of the grape contains water, sugar, mucilage, some fermentative matters, tartaric acid in the form of tartar, and other free acid, besides those peculiar etherial principles which give the flavor both before and after the fermentation. The principal change which takes place when the juice is exposed to the air is, the commencement of the conversion of the sugar into alcohol and carbonic acid. A portion of the sugar is thus destroyed, spirit is left in the fluid, the carbonic acid escapes in bubbles which make the effervescence (the working,) and certain other changes take place also affecting the flavor. After vinous fermentation commences, it goes on without access of air, and but a very slight contact with the air is sufficient to start it. It depends upon a change which takes place in the nitrogenous or albuminous principles of the fruit, and these, originally in solution, become insoluble, at first floating in the fluid, rendering it turbid, and finally settling as *lees* to the bottom.

How to Make the Best Cider.

Apple juice, tolerably pure, put into barrels with the bungs out, and a bottle neck, or a wisp of straw tucked into the bung-hole, and set in the shade somewhere, makes first, sweet cider, then cider, next hard cider, and finally, vinegar, without much care. When, however, the juice of ripe, rich apples, free from decay, leaves, dirt, and water, is strained into clean barrels, set in a cool cellar, and racked off when the fermentation has nearly ceased, and the cider is nearly clear, a very different article is produced, having a fragrance and purity entirely wanting in the common article. The slight vinegary taste of hard cider is also wanting, and the "hardness" is of the same quality as the dryness of the acid, or dry wines. Cider thus made is very properly called by our German friends *Apfel Wein*.

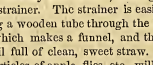
It is a mistake to suppose that early Autumn apples will not make good cider, for that of some varieties is remarkably high-toned. It is seldom perhaps that there is enough of these early apples to make a large quantity of cider, and this is probably the reason why they are neglected; and on account of the neglect, the stigma attaches to them that they are good for nothing. A hand-press is an exceedingly convenient thing upon a farm, particularly such an one as may be used equally well for apples, pears, currants, blackberries, and grapes; and by it a great deal of fruit may be made valuable, which would otherwise be lost. One mill will answer for grinding apples for several presses.

Though the cider made from a mixture of several kinds of apples is very good, if well made, it is much better, if practicable, to keep the juice of different apples separate. In this case the delicate and distinctive flavors of the fruits are retained very agreeably in the cider.

The most scrupulous cleanliness must obtain from first to last. First, the barrels into which the cider is to be placed must be thoroughly washed out and fumigated with sulphur, which is done, after preparing strips of cotton-cloth by dipping them in melted sulphur, by setting them on fire, putting them into the still moist barrel, and bunging it up so that the sulphured rag shall be held by the bung. The mill and press, tubs, funnel, and dippers being also well cleansed, the apples are looked over, decayed ones thrown out, the dirt rubbed off, and they are then ground to a fine pulp.

The common way of laying up a cheese with wet straw has several disadvantages, particularly the necessary use of water to wet the straw, which is equivalent to an addition of water to the juice; then, too, the straw always retains much of the juice. The small presses alluded to, which work without straw, yield a better article of cider. To judge of the quality of cider an apple will make, it is best to try an experiment, grinding a small quantity, letting the pomace stand half a day, stirring it occasionally, and then pressing it. The difference in the color and richness of flavor, and of sweetness, is quite remarkable. Sweet apples, though containing more sugar, are often watery and deficient in flavor, while many sub-acid, or even sour apples, contain as much sugar, and make a much richer cider. The juice, when first pressed, should be syrupy, clear, and the darker colored the better. Apples vary also greatly in the quantity of cider they will make; of many kinds no more than eight bushels will make a barrel of cider, while of some of the richer, finer kinds it will take twelve bushels or more.

It is poor policy to grind and press at once. A bruised apple gains in sweetness, by some chemical change which takes place—and so the pomace should lie several hours to sweeten in this way; and besides, it should be stirred up occasionally to let the air get to it, so as to impart a better color. The dark red color is very desirable, and can not be gained in any other way, and at the same time there is a positive gain in sweetness and richness to the cider.



BUNG-HOLE CLOSED BY A WATER-VALVE.

As the juice runs from the press, it is best received directly into barrels, flowing through a straw strainer. The strainer is easily made by putting a wooden tube through the bottom of a pail, which makes a funnel, and then stuffing the pail full of clean, sweet straw. Almost all the particles of apple, flies, etc., will be strained out, and a clear liquid alone will pass through. The barrels, large or small, are filled full, bunged up and moved to a cool cellar, where the bungs are removed and the cider left to ferment.

The fermentation goes on quite rapidly, and a considerable portion of scum overflows and is thus removed. When the active fermentation and frothing cease, and the bubbles crackle as they rise to the surface and break, the bung-hole should be closed by a large cork, (see figure) through which a glass or leaden tube, bent twice at right angles, is thrust, which rises from the bung and dips below water in some convenient small vessel, through which tube this gas will escape, but air can not enter. When the fermentation is over, and no more bubbling at the end of this tube occurs, and the cider is clear, draw it off into clean, fumigated barrels, bung up tight, and keep in the coolest place.

Fall Butter.

The time of the year when that temperature prevails at which milk neither freezes nor quickly sours, at which cream rises perfectly, and when it requires least care to have the cream at the best temperature for churning, is the best for butter-making. We have these conditions both in Spring and Fall. In the Spring the cows are in full milk, the cares of the dairy and household are multifarious, and the butter, if made in quantity, must be marketed at once or kept through the Summer, and unfortunately not one in a thousand can make Spring butter that will keep well. Autumn is therefore the time of all others when most and the best butter is made.

The important things in butter making are to secure all the cream, to keep it clean, to churn it before it has stood too long, to separate the buttermilk thoroughly from the butter, to work the salt in uniformly, and to do all this without touching it with the hands.

If the milk is carried half a mile and stands half an hour before it is strained into pans, you will certainly lose butter, for the cream will not rise so well. Let the distance that the milk is brought, and the delay before straining it into pans where it will not be moved, be as short as possible. There are no better pans than the common tin pans in use in this country, unless it be some of those forms which allow of the milk being drawn off from the bottom, leaving the cream undisturbed, and, as far as possible, free from milk.

After standing 36 hours the cream will have risen, and if the weather is not too cold it will form quite a firm film upon the surface, which may be removed without taking up an appreciable quantity of milk. This is very desirable, for the cheesy portions of the milk should all be left behind, so far as possible. The cream is best put into stone-ware jars, and kept cool and clean. It is a mistaken notion that cream should be sweet to make the best butter. It must, however, be observed that cream attracts odors and flavors with astonishing facility, so much that the butter will often taste distinctly of articles which were cooking near the dairy at the time the milk was put to stand for cream. This facility to acquire unpleasant odors and flavors will account for a vast deal of ill-flavored butter, which occurs to the disappointment of those who take a great deal of pains, but overlook or are ignorant of this important fact.

The cream should be stirred whenever it is necessary to keep it long in the pot or jar, so that it shall have a uniform consistency and be uniformly exposed to the influences of the atmosphere. After the cream has acquired a slight degree of acidity the sooner it is churned the better.

The thermometer churn is the best we know of; indeed the only really philosophical churn is one which enables us to regulate accurately the temperature of the cream. Modes of agitation, etc., however important, are of a secondary consideration. Cream should be of a temperature not below 55° Fahrenheit, when the churning begins, nor should it be much above that, for the heat increases as the churning proceeds, and when the butter has come it will be near 60°, and ought not to be above 65° on any account. When the butter has come, the churn should be opened and the sides, top and all parts where cream or butter may collect scraped down. After "gathering," the buttermilk should be drawn off and, according to one process, the butter washed—as much spring water at 60° being put in as there was milk. When this is churned in contact with the butter for a minute or two, it is drawn off and more added. Two or three washings like this will free the butter from buttermilk so effectually that after it is thoroughly

worked with wooden ladles or "spatters" to get the water out with the last traces of buttermilk, the salt may be worked in and the butter considered made, except what working and compacting it gets in balling up, at which time every drop of moisture that can be extracted is clear gain. The hand should never touch the cream or the butter from first to last. If specks be seen, remove them with the point of a knife, or a stick made for the purpose. The dairy-woman should educate her own mind to feel that though she knows her own hands are perfectly clean, and that they have not touched her head or her clothes, or any thing else, still the handling or touching the butter with bare hands is unworthy a good dairy-woman, and must never be done.

The vessels and implements used in butter-making should not only be clean, but they should be scalded and then rinsed off in cold water every time just before they are used. The best table for working butter on is one of marble, with a groove all round, an inch and a half from the edge. Beach is the best wood for the ladles and "spatters." A common pastry rolling pin, or one that has shallow longitudinal flutings in it, is a capital thing to work butter with; and a soft sponge covered with a fine linen cloth, kept constantly wet and clean by dipping it in cold, pure water, and wringing it out, is excellent to take up the buttermilk which is brought to light by the rolling. This is a very neat, expeditious and easy process.

Well worked butter does not require much salt; half an ounce to the pound is enough for that which is to be consumed at once or marketed, unless the market demands a salter article, and for the real butter lover no salt at all is decidedly preferable. Butter to be packed in firkins requires more salt, and should be worked again after salting, which reduces the quantity somewhat, and should finally contain not more than one ounce of salt to the pound. The firkins should be prepared by first tightening the hoops, then filling with boiling hot water, and letting them soak half a day, and repeating the operation, and finally, after they have become partially dry, scalding them out with hot brine and letting them dry without wiping. This takes out the taste of the wood. There is no object in using large quantities of salt between the layers of butter and upon the top, but on the contrary it is injurious. Every part of the firkin should be filled with butter, so that no air can penetrate; a thin film of fine salt, however, should line the sides and bottom, and cover the top.

Onions in a Hygienic Point of View.

In a medicinal point of view, the garden onion is of more importance than any other of our esculent vegetables. It is a powerful diuretic, and is said as such to have been successfully used as a specific in dropsy, gout, gravel, lumbago, and generally in all affections of the kidneys and urinary organs. As an instance of its efficacy in dropsy, we shall relate a circumstance which came within our own observation a few years since. We were traveling through one of the middle departments of France in company with a very eminent connsellor, and member of the Parisian Bar, who had turned his attention to discovering the various medicinal properties of simples, in illustration of a favorite theory of his, that all the ailments which afflict mankind may be removed by remedies from the vegetable kingdom, to the utter exclusion of all mineral substances.

One day we stopped and claimed the privileges of hospitality at a beautiful "chateau" belonging to a distant relative of our friend. We were most kindly received by the lord of the manslon, a fine looking middle aged man, who, with tears in his eyes, informed us that his lady, whom our friend described as a most gentle, kind-hearted, and noble-minded dame, was dying of the dropsy, all the medical men in the neighborhood having stated that nothing more could be done for her. "That remains to be seen," said our friend hastily, "I must see her forthwith," and he proceeded to her bedroom, dragging us with him—a circumstance which will create no surprise in those acquainted with the manners of the French. The lady was alarmingly ill, and had swollen to an enormous size; she had been tapped once before, but on the present occasion had obstinately refused such a mode of relief. The Parisian lawyer, nothing daunted, called for some *white onions*. Having peeled a sufficient quantity, he filled with them a pipkin, or coarse earthen mug, holding about three pints. Having stuffed in as many peeled onions as the vessel would contain, he filled this with cold water, covered it, and set it in the midst of the warm embers, where the water would simmer with very little ebullition. He let the onions stew until they were reduced to a pap, and the water to half of the original quantity—a process which required three or four hours, as the vessel was kept closely covered, and the fire slow. He strained the liquor through a linen bag, carefully expressing every drop of juice from the onion pulp which had melted in the liquor. Having extracted this latter, he carefully weighed it, and then, gently over the fire, but without boiling, dissolved in it its own weight of coarse brown sugar. Of this syrup he gave his patient two tablespoonfuls every two hours, a fresh quantity being made so as to keep up a constant supply. In a day or two the lady felt better, and in about six weeks, during which time we remained at the chateau as guests, she was able to walk with us about the grounds. We had occasion to visit our kind host about six months after our former visit, and found his lady enjoying excellent health, and valuing her cousin's onion syrup as a specific for all the complaints "that flesh is heir to."—*Mag. Domestic Economy*, (Eng).

For the American Agriculturist.

About Pickles, etc.

Allow me to add to your list of "Material for Pickles," and your recipes for pickling, one or two which are very palatable, and entirely economical:

OTHER TOMATO PICKLES.

Use the multitudes of tomatoes of all sizes, which remain green on the vines when Jack Frost is drawing near, in this manner: Chop them to about the size of dice, place them in colanders with a little salt, and let them drain one day; then put them in jars, and cover them with hot vinegar well spiced, and set them away. They require no further care, and have very much the relish of mangoes.

A kind of *mango* can be made of the very large tomatoes which remain green. Cut out with the stem enough of the tomato to permit the scooping out of the seeds, and then fill with chopped cabbage, chopped onions, with mustard seed and spices, or any thing which is preferred. Secure the piece cut out, as you would in making melon mangoes, and then throw the tomatoes with your other pickles into vinegar.

BOILED QUINCES FOR THE DESSERT.

You furnish also a recipe for "baked quinces." I assure you that quinces not pared, simply boiled in fair water till tender, and eaten with butter and sugar, like dumplings, form a delicious dessert for the dinner table. They should be taken upon the plate and crushed with the fork, and simply buttered and sugared. As to beauty, nothing can surpass them; they retain their form, and are as bright as a dish of oranges. LETTY ERMIN.

Preserving Peaches.

It may be done either with or without sugar, with much or with little. The question may well be considered, will sugar be cheaper next Winter and Spring than now, and we may act accordingly. Pecl and cut in quarters, put them directly into the bottles, with a *very* little water, put the bottles in a wash-boller, or similar vessel, filled with water to within two inches of the tops of the jars; bring the water to a boil, and boil it 15 minutes. Have prepared a syrup with 1 pound of sugar to a pint of water, or 1 pound to 2 quarts, just as you choose—the former usually preferable—pour this, boiling hot, into the bottles, as soon as they are removed from the water, and close them immediately, as directed on page 182, *Agriculturist* for June, 1862.

Hints About Cooking, etc.

Pea Soup.—People who despise soups had better try either of the following recipes. The first is an old family recipe; the other is from Soyer, who has furnished *the people* so many good recipes.

Split Pea Soup.—Take a quart of peas; soak the peas over night in a quart of water; in the morning boil them an hour in this water; 10 minutes before the hour expires, put in a teaspoonful of saleratus; at the expiration of the hour, change them to fresh water; put in a pound of salt pork, and boil three or four hours. Serve with a slice or two of bread, cut in small cubes and fried brown.

Cheap Pea Soup.—Put into the iron pot two ounces of drippings, one quarter of a pound of bacon, cut into dice, two good onions sliced; fry them gently until brownish, then add one large or two small turnips, the same of carrots, one leek, and one head of celery, all cut thin and slanting (if all these can not be obtained, use any of them, but about the same amount); fry for ten minutes more, and then add seven quarts of water; boil up, and add one pound and a half of split peas; simmer for two or three hours, until reduced to a pulp, which depends on the quality of the peas; then add two tablespoonfuls of salt, one of sugar, one of dried mint; mix half a pound of flour smooth in a pint of water, stir it well, pour in the soup, boil thirty minutes, and serve.

Green Pickles.—To give pickles a lively green color, it is recommended to put grape leaves into the vinegar—a very simple way if it is effective.

Corn Oysters.—Half a dozen ears of boiled corn; three eggs; a tablespoonful and a-half of flour. Beat the yolks very thick; cut the corn off the cob; season it with pepper and salt; mix it with the yolks, and add the flour. Whisk the whites to a stiff froth; stir them in with the corn and yolks; put a dessert spoonful at a time in a pan of hot butter, and fry to a light brown on both sides.

Biscuit Fritters.—Take some light biscuits or rusks; split them in halves; saturate them with custard made with six eggs to a quart of milk, omitting sugar (if the cakes are sweet); then fry them in hot lard to a light brown, and eat with wine sauce.

To Candy Fruits.—Take one pound of the best loaf sugar; dip each lump into a bowl of water, and put the sugar into your preserving kettle. Boil it down and skim it until perfectly clear, and in a candying state. When sufficiently boiled, have ready the fruits you wish to preserve. Large white grapes, oranges separated into small pieces, or preserved fruits, taken out of their syrup and dried, are very nice. Dip the fruits into the prepared sugar while it is hot; put them in a cold place; they soon become hard.

Pineapple Jam.—Pare the pineapples, and grate or shred them fine with a silver fork. To every 5 pounds of fruit add 3 pounds of loaf sugar. Put the whole on the fire, and boil it three-quarters of an hour, stirring it all the while. When cold, put it in jars with brandy paper on the top, and tie them close, or paste paper over, and keep in a dry, cool place.

Sweet Apples Baked and Dried.—Bake as for the table; then dry by fire heat. The old-fashioned, large brick oven is the best place. When wanted for the table they may be soaked in water and heated, and finally the water dried away. The apples return to very nearly the condition of fresh baked apples. If they are stewed in a syrup they make a rich sauce, far preferable to that of the common dried apples. A FARMER'S WIFE.
Licking Co., Ohio.

To Destroy Moths in Carpets.—Remove the furniture and whip the edges of the carpet repeatedly with a strong whip, (a good rawhide.) A good housekeeper writes that she has tried this method with success.

RAMBLES AMONG THE MOUNTAINS

Engraved for the American Agriculturist.

Some of our young readers live by the Sea-shore, where the great waves of the Atlantic, or of the Pacific, come rolling in, thundering upon the beach with a hollow, rumbling sound, which at a little distance fills the ear with a strange, solemn melody. Many others see the waving grain and grass of the gently rolling or level prairies, which, like the ocean, stretch for miles away, so far as the eye can reach—no rocks, no hills, no mountains and forests; but beautiful corn and fine herds of cattle and sheep cover the prairies. Others live upon the mountains, where huge rocky bluffs and peaks stand up and take the brunt of the storms and tempest, or cool the hot winds of summer-time. Here the dew falls early, and the breezes blow cool, and here grow sweet, short grasses whereon the sheep and goats thrive so well, and fed upon which the cows give such rich milk and sweet butter. We have here a picture of a wild mountain scene; and in the hot days of the past month we think many of our city readers would gladly have changed places with this little girl in her rambles among the wild flowers, the rocks and the flocks of the cool mountains.

The Editor with his Young Readers.

LETTERS FROM MR. JUDD.... NO. II.

LONDON, *England, July 9th*, 1862.

DEAR YOUNG READERS:—I am just leaving this City for a trip on the Continent, but will send you a few notes, which must be dispatched thus early, in order to cross the Atlantic in time for the inside sheet of the September *Agriculturist*.—My last letter closed up at Belfast, Ireland. From there we went by steamboat about 160 miles, passing up the river Clyde, to Glasgow, Scotland. Along this river are very extensive ship-yards, where iron-clad and other vessels are being built. At one point we saw the west end of "*Antonine' Wall*," or "Graham's Dyke," a great embankment built clear across Scotland when the Romans occupied England, many hundreds of years ago. Neither the Romans nor the English were ever able to penetrate to the extreme north of Scotland. The Scotch people boast, and I believe truly, that their country has never been entirely occupied or conquered by any other people. No other European nation can make a similar boast. (The union of Scotland and England was brought about by marriage and inheritance among the Royal families.)—Glasgow is a fine city. The Clyde has been *made* navigable up to this city by digging out and straightening the channels, and building up artificial banks. The "*Broomielaw*" or harbor, is an artificial basin, upwards of a mile in length, and more than 400 feet wide, and contains over *fifty acres* of water in which ships float. Glasgow contains about 400,000 inhabitants, or about 450,000 including the suburbs. The illustrious James Watt began his memorable experiments upon steam engines at Glasgow, in 1763, or 100 years ago. The first steamboat successfully run in Europe plied between Glasgow and Greenock, a town at the mouth of the Clyde, commencing her trip Jan. 18, 1812, the first year of our last war with England. The engine of this little steamboat, called the "Comet," was only 3-horse-power. (Please get out your maps and hunt up the Clyde River and Firth, and note the location of Ayr, and of Edinburgh.) Glasgow is largely engaged in commerce with all parts of the world. The city is well laid out, cleanly, and the houses high, in good taste, and all of light-colored stone.

I could not resist the desire to visit the birth place of Robert Burns, near the village of Ayr, 40 miles southwest of Glasgow. When I was a boy upon the old farm, several Scotch laborers were employed, and they often sat for hours in the evening playing the flute and singing "Bonny Doon," the "Banks of Ayr," etc. The big tears coursed down their cheeks as they sung and talked of their loved native land. The little boy who then listened to them and even wept with them, little dreamed that more than 30 years afterwards he would ramble along the banks of the Ayr and Doon rivers, and enter the low, straw-thatched cottage where the poet Burns was born, visit the "Auld Kirk," and the tomb of the poet, and take a run over "Tam O'Shanter's" Bridge. But such was my privilege on June 14th, 1862, and the scenes will never be forgotten, more than will the earlier boyhood days and the kindly Scotchmen who sung to me those plaintive songs. The country around Ayr, and between there and Glasgow, is finely cultivated, resembling some of the best agricultural regions in our own country.

EDINBURGH, (pronounced "Ed-in-bo-ro") is a city of nearly 200,000 inhabitants, situated on or near the Firth (bay) of Forth. In the southeast part of Scotland. Taken altogether, it is the finest city I have ever seen. A high hill near the center of the city is capped by a large, old castle, strongly built, and only to be entered by means of a drawbridge over a deep ditch. Along the south of this is the old city; the streets narrow, the stone houses many stories high. A high wall, yet partly remaining, enclosed the ancient city, and the space being limited the houses were built very high, to save ground room. Many of them run up 10 to 12 stories; one or more families occupy each story.——The new city extends all round outside of the old walls, but mainly northward, running to Leith, the harbor of the city. The streets of the new city are wide, very clean, and the houses in excellent (modern) style. There are many buildings and objects of interest, but I can not stop to describe them particularly, as I have *many* notes of other interesting localities to draw upon. It is worth a pilgrimage to go upon the top of "Arthur's Seat," a very high hill a little way southeast of Edinburgh, and look down upon the city, the Firth, the beautiful Lothian Farms for dozens of miles to the South, etc. From its summit we can also see the Grampian Hills far north of the Firth of Forth, also Ben Lomond away northwest of Glasgow on the western coast of Scotland.

Long Days.—In my note-book is this memorandum. "Edinburgh, June 14th, 10¾ P. M. I am writing by *daylight!* In these high latitudes (56° North) the sun shines round the northern side of the earth, so to speak, and we have daylight bright enough to read from 2¾ A. M., to 10¼ P. M., at this season of the year. A dozen degrees further north, the sun shines clear over the North Pole at all hours, affording perpetual day when the sun is at the 'Summer Solstice.' Even here in London (lat. 51½°), it is light enough to read after 9 o'clock P. M. (July 9th)."

EDINBURGH TO LONDON.

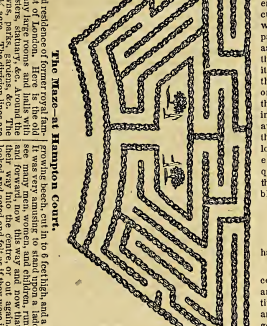
Size of England.—In all the maps used in our own country, England occupies so small a place in an upper corner, that we are accustomed from early childhood to think of it as a diminutive island. I suspect that most people insensibly allot about as much space to some of our smaller States as they do to all of England, owing to the little space it occupies on *our* common maps. This is a false impression. Such a ride as I took, of 400 *miles* (or just 300¾ miles) through the country from Edinburgh to London, is well calculated to do away with such early geographical impressions. Our route, of course, was not a straight line, yet the most direct one by railway. We first went southeast 57 miles to Berwick, thence south 67 miles to New-Castle-upon-Tyne, thence 94 miles to York, then 115 miles to Peterboro, and 76 miles to London, which is still about 75 miles North of the English Channel.——England alone contains 50,922 square miles. The Great Empire State (New-York) contains 50,519 square miles—a difference of barely 403 square miles. Wales, which is really a part of England, contains 7,398 square miles, or about the same as the State of Massachusetts. Ireland contains 32,508 square miles, or nearly as much as the State of Indiana. Scotland (including 500 miles in its islands) contains 31,324 square miles, or nearly as much as the State of Maine. The total area of Great Britain and Ireland is therefore **122,152** square miles, or about the same as the combined States of New-York, Maine, Massachusetts, and Indiana, or a little more than the whole of New-England, New-York, and New-Jersey.——(The entire territory of the United States is 3,200,000 square miles, or *twenty-six* times that of all Great Britain.) The population of Great Britain is at present not far from Thirty Millions, or a little less than half of the United States. With a territory so large, and so highly cultivated, it is not so much to be wondered at, that in very plenteous years Great Britain should produce almost food enough to sustain her own population, though in ordinary years from fifty to seventy-five million bushels of grain are imported. If all the great landed estates, the wooded hunting grounds, and the imperfectly cultivated lands of Ireland were under the best tillage, and the grain consumed in producing *beer* were used as food, Great Britain would readily feed her whole population from her own soil. Taken as a whole, the *proportion* of good soil is no greater in Great Britain than in the United States. What will be the feeding capacity of *our* entire country when it is all brought into the highest and most productive cultivation! You, boys, are to have a hand in the tillage of our broad territory. Every acre of our good soils is a mine of wealth. You should prepare yourselves by study, by reading, and by observation, to enter well upon your future work; you will soon be *directors* of our farming and other pursuits.

The whole eastern part of the country, from Edinburgh to London, is one vast cultivated field, with the exception of here and there a reserved hunting forest, a few hilly spots, some barren heaths, and a few few swampy bogs. In some places, as around New-Castle, the fields are much broken up by the openings to the coal beds we know underlie the surface. Scarcely a wooden fence is to be seen, and very few iron ones. The farms and fields are divided by green hawthorn hedges. (The same thing is seen in Ireland, and more or less in Scotland.) These "living fences" add much to the beauty of the landscape in Summer, yet for profit and convenience these hedges are far too abundant. We shall not find them on the Continent of Europe. They occupy much ground, and are the fruitful nests of foul weeds and vermin. We shall probably come to hedges in America, if our climate does not prove too hot and dry for them; but we shall scarcely commit the error of cutting up our fields into plots of one to five acres, by hedges and ditches. English farmers are fast diminishing the division lines, even where the large estates are being cut up into small freehold farms. (Much of the soil of England is owned by great land holders who let it to tenants by the acre. We conversed with one farmer who cultivates 2,500 acres, for which he pays an annual rent of $3 to $16 an acre

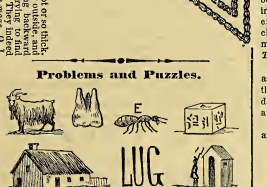
My letter is already too long, to leave room to say any thing about the city of London, the great International Exhibition, &c. I will enclose in this a sketch of a place I visited last week, called

The Maze--at Hampton Court.

—Hampton Court is the old residence of former royal families. It is situated on the River Thames, about 12 miles from London. Here is the old Palace, and the Parks, and Gardens, and Pleasure Grounds, filled with statuary and paintings by the great masters. Among the latter is the celebrated cartoons of Raphael. The Maze, or Labyrinth, contains perhaps 1 acre. The division lines are formed by a hedge of evergreen trees, about 6 feet high, and so close and thick that it is impossible to see through them. The hedge is trimmed with shears, and looks as neat and even as if it were a mere wall. Of course, the only way to find the centre is to find the way. The way is not difficult, as there is but one path, and that winds around and around, and forward, now this way and now that, trying to find the way. Many persons, however, get lost in the Maze, and are unable to find the way out for hours. Sometimes they call for help, and are assisted out by the gardeners, who are stationed at the entrance for that purpose. Many persons, however, prefer to get lost, and wander about for hours, rather than call for help. The engraving below represents a portion of the Maze, with a person in the centre, who has evidently got lost, and is looking around for the way out. The trees are about 20 feet high, and a foot or so thick. The hedge is 6 feet high, and 6 feet thick. The ground is level, and the trees grow in a straight line. The engraving below represents a portion of the Maze, with a person in the centre, who has evidently got lost, and is looking around for the way out. The trees are about 20 feet high, and a foot or so thick. The hedge is 6 feet high, and 6 feet or so thick.

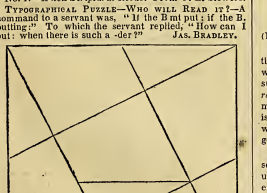


Problems and Puzzles.



No. 17—*A new Scriptural Rebus.* From C. L. Siewers.

TYPOGRAPHICAL PUZZLE—WHO WILL READ IT?—A command to a servant was, "If the B mt put; if the B. putting:" To which the servant replied, "How can I put: when there is such a -der?" JAS. BRADLEY.



Answer to Block Puzzle No. 16 (page 249, August):

Answer to the Rebus No. 12 (page 217, July) :—"Oft repeated sin deadens conscience."

Answer to the Rebus No. 13 (page 217, July) :—"A Cat in gloves catches no mice," thus;—Cat inn gloves cat cheese no mice *(none in the trap).*

Answer to the Rebus No. 15: (page 249, August)—"A people intent on being ruled by a king, need not complain if monarchs arrogate their ability to overrule opinions," thus:——A *people in tent on bee* in G ruled by *a king have* d *knot* com *play* n if m on *arcs arrow gate* their *a bill* tly 2 over rule *o pinions.*

The Quill and Card Experiment.

One of the prettiest of those little philosophical experiments which everybody may make, is the following: Take two pieces of light card or stiff paper, and cut them out circular and exactly of a size—about 3 inches or less in diameter; in the middle of one of them make a hole and insert a goose quill or other similar tube. The end of the quill must be cut off square and even with the card. It may be pasted or gummed so as to stick—now blow through the quill holding it in the mouth, and place the other card against the one attached to the quill: the result will be that, instead of being blown away it will be drawn up tightly to the quill-card, and the harder you blow the tighter it will stick. The philosophy of this is very *evident* and simple to explain, however difficult to demonstrate. The cut shows how the quill is inserted. Let some of our young readers make the experiment and see if they can tell why they can not blow the card away.

A Constant Exhibition.

The Tables at the Office of the *American Agriculturist* have constantly during the season novel and interesting

FRUITS, FLOWERS, GRAINS, VEGETABLES, ETC.,

contributed by SUBSCRIBERS, NURSERYMEN, GARDENERS and others, and almost uniformly present a very attractive and instructive exhibition. The daily show of fruits and flowers is now large and interesting. It has been suggested by horticultural gentlemen of this city and neighborhood that we have a WEEKLY EXHIBITION, appointing a *certain day* whereon our friends may come with the expectation of seeing one another, and talking over their choice fruits, etc. This is a good idea, and while we are most happy to receive contributions to our *Exhibition Tables* EVERY DAY, we name

THURSDAY OF EACH WEEK

as a convenient day for a special show of FRUITS during this and the following two or three months; on which days we shall be especially happy to see our friends, who are at all times most heartily welcome.

Our tables are spacious, and the Office large and airy, and the best care will be taken of the articles contributed.

PREMIUM LIST,

For 1863---Volume XXII.

New Subscribers get the Rest of this Year Without Charge. (*See page* 288.)

Good Pay to Voluntary Agents who attend to Collecting and forwarding Clubs of Subscribers to the American Agriculturist.

(Premiums open to all who Desire them.)

Every subscriber is invited to renew his own subscription, and to solicit others to subscribe. But to all those who will take the trouble to collect and forward CLUBS of subscribers, we offer a remuneration in the form of *first-rate* articles, as named below. The pay thus offered is much larger than we could pay in cash, though no article is proposed which is not of the best quality, and fully worth the price asked. (We get these articles on extra good terms *when for premiums.*)

Part of the Premium articles announced this month are selected from the best prizes last year, those which gave universal satisfaction. They are such as will *pay* for the effort to obtain them.

☞ WE WISH IT DISTINCTLY UNDERSTOOD *that these premiums are offered in good faith—no cheap, trashy, imperfect, poorly made, or second-hand thing, will be sent out, but each article offered, is the best of its kind, and every one will be selected by the publisher from the very best manufactured. They will be the best sold in the market at the prices named.*

☞ We offer nothing *for competition.* Each premium is for a specified number of subscribers, and no one's remuneration will depend upon what other unknown persons are doing; every one knows just what he or she is working for.

☞ *We make no distinction between new and old subscribers,* but it is expected that every canvasser will not only gather up the names of old subscribers, but also secure a large number of new names.

☞ Every person collecting names for premiums, should send two copies of each list of names—one of them marked "For Premiums," and also with the name of the sender.

☞ Every person collecting names for premiums, should send the names with the money as fast as obtained, so that the subscribers may begin to receive their papers; but if designed for premiums, two copies of each list of names should be sent—one of them marked at the top "For Premiums," and also with the name of the sender.

☞ The premiums are offered for subscribers for Volume XXII (1863), *whenever received.* Canvassers will have time for completing their lists, but the premium will be paid as soon as any club is made up—if duplicate lists are sent.

☞ Any person who has commenced sending in names at 80c. and finally falls to get the higher number of names, can fall back upon the smaller number, by remitting the 20 cents extra on each of the smaller number of names required.

☞ Clubs need not be all confined to one Post Office.

Table of Premiums for 1863.

Names of Premium Articles.	Price of Premium.	Names at $1 each.	Names at 80c. each
1—Goop BOOKS—*See terms below*.....			
2—Best Family Clothes Wringer.....	$7 50	18	37
3—Nonpareil Washing Machine.....	$14 00	30	70
4—Sewing Machine, (Wheeler & Wilson).....	$45 00	90	139
5—Sewing Machine, (Wilcox & Gibbs).....	$50 00	96	168
6—Aneroid Barometer.....	$7 50	19	44
7—The Aquarium.....	$10 00	25	47
8—Five octave Melodeon (best).....	$75 00	125	257
9—Six Octave Melodeon (best).....	$90 00	194	382

DESCRIPTION OF THE PREMIUMS.

Premium No. 1—Good Books.

This premium will meet the wants of a great number of persons. On page 285 is a list of 92 books, many of them on topics connected with the Farm, Garden, and Household, and a portion of them the very best published. (See remarks at the head of the list.) Any person sending in 16 or more subscribers, may select any of the books in that list, (page 285,) to the amount of 12½ *cents for each name, at the club price of* 80 *cents, or to the amount of* 33½ *cents for each name, at* $1 *each.* Many farmers' clubs have, during the last year, joined together and obtained a considerable library through these premiums. N. B.—The books will be *delivered* to the recipients (by mail or express, *free of all cost.*

No. 2—Family Clothes-Wringer.

This is a first-rate household implement—a great saver of garments, and a saver of hard work. Every woman knows that wringing by hand is not only the hardest, wrenching work of washing-day, but that the twisting by hand-wringing breaks more of the fibres of the garments than the washing and ordinary wear. With this machine set upon the edge of the wash-tub, the garments are easily and rapidly passed between two India-rubber rollers, the water falling back into the tub, and the garments dropping into a basket, in a drier condition than they can be wrung by hand, and therefore more quickly dried on the line. A child can in a few minutes wring out a tubful of clothes. The machine will save its cost several times in a year, simply in the saving of garments. We have had one of the first machines made in constant use in a family for nearly three years, and it is still as good as new. The machines now manufactured are still better, several improvements having been made. The machine figured, No. 2, is just the thing for family use. It is provided with cogs to move the rollers together, so that it is not possible to tear garments, as is the case with cheaper Wringers not provided with cogs. We present one of these No. 2 Wringers to any person procuring and forwarding 18 subscribers, at $1 each, or 37 at the lowest club price, (80 cents each.)

Premium No. 3—Best Washing Machine.

Many ladies have asked us, for years past, to introduce a good Washing Machine among our Premium articles, but we have uniformly declined doing so, for want of the right kind of machine. We have now, however, found a machine worthy of a place in the premium list, in which we mean to put none but those known to be first-rate articles. The **Nonpareil Washing Machine** we have had in use in our family for nearly a year past, and it has not only driven out half-a-dozen placed there on trial, but has really given excellent satisfaction. It is the only machine, out of twenty we have tried, which the "help" cheerfully use without compulsion. It is a labor-saver and a clothes-saver—two important considerations. (See descriptive cut, and advertisement on page 287.) The clothes are put in, in quantity, and quickly washed by simply turning a crank. The balance-wheel adjusts the force required, so as to make the turning easy. Take it all in all, it is the best Washing Machine we know of, and is worthy of a place in every family. They are of three sizes; we select No. 2, as the best size for common family use. The price of No. 2 is $14. This machine we will present to any one for warding 30 subscribers at the regular price, ($1 each,) or 70 subscribers at the lowest club price, (80 cents.) The machine can be sent to any point as freight, or by express, and will be forwarded, free of all expense, except the freight after leaving the city.

Premium No. 4—Sewing Machine.

90 Subscribers at $1 each, (or **130** at 80 cents each,) will entitle the person sending them to *Wheeler & Wilson's* best **$45 Sewing Machine,** (including **Hemmer**), new from the factory, and of the very best make. There is no better family machine than this made, as we have proved by nearly *five* years' use in our own family, in connection with other machines. We want no better. The fact that more of the Wheeler & Wilson machines are sold than of all others combined, is perhaps the best testimony in their favor. The terms on which it is offered above, will enable many families to secure one without direct outlay of money. The Premium Machines will be selected new at the manufactory, and will be forwarded, well boxed, with full directions for setting up and using, and with no expense, except for freight, after leaving the city.

Premium No. 5—Sewing Machine.

60 Subscribers at $1 each, (or **98** at 80 cents each,) will entitle the person procuring them to *Wilcox & Gibbs'* **$35 Sewing Machine,** including a set of **Hemmers.** This is the best machine of its kind, (sewing with one thread,) and has several points superior to other machines. It is neat, well made, simple in its operation; and having tested one in our own family for more than two years, we think highly of it, and can recommend it to those who can not afford to buy the higher priced double-thread machines. Most of our neighbors think this machine ahead of all others. Premium 5 will be selected and sent the same as No. 4.

Premium No. 6—Barometer.

19 Subscribers at $1 each, (or **44** at 80 cents each,) will entitle the person getting up the club to one of *Kendall's* **Aneroid Barometers,** (Price $15.) This is a good, portable instrument, and valuable to every person as a weather guide, as well as for scientific purposes. We have had one in use for nearly three years, and find it not only accurate, but an admirable weather prophet. Scarcely a rain storm or gale of wind has occurred, that has not been heralded by our barometer. It will save to any farmer and others many times its cost, as a weather-indicator. These instruments resemble a large watch, 5 inches in diameter, and 2 inches thick. Each one is in a neat leather case, and when sent to a distance, this is packed in cotton, in a wooden box 4¼ by 8 inches, and can go anywhere, by express or otherwise, with perfect safety.

Premium No. 7—The Aquarius.

This is a capital instrument, valuable to have in every house. It is a portable hand force-pump, which any one can catch up at a moment's warning, and throw from a pail or other vessel a steady stream of water upon a fire in a house, or elsewhere. It is supplied with both a jet-pipe and a rose, or sprinkler, and can be used for washing windows, carriages, &c.; for sprinkling trees, plants, destroying insects, &c., &c. With it, it is easy to wash the second and third story windows, and to sprinkle the roof of a house without standing upon the ground. Such an apparatus will often enable a person to so use a bucket or two of water as to extinguish a fire breaking out where it could not be reached by engines from the street. The Aquarius is supplied with suction and injection India-rubber pipes, and with air-chambers to keep up a constant stream. The weight is 8 lbs., and it can be sent anywhere as freight, or by express. We substitute this for the Hydropult, as being cheaper, and quite as good, (Price $10.) We will present an **Aquarius** complete to any one forwarding a club of **22** subscribers at $1 each, (or **47** at 80 cents each.) N. B.—Further particulars can be obtained by sending for a descriptive circular to the manufacturers, W. & B. Douglas, Middletown, Conn.

Premium No. 8—Melodeon.

125 Subscribers at $1 each, (or **237** at 80 cents each,) will entitle the person getting up the club to one of *Geo. A. Prince & Co.'s* **$75 Melodeons** (5 octaves). These Melodeons are of very superior tone and finish. We have ourselves used one for three years past, and it has given the highest satisfaction, and is considered by all who have heard it, as one of the very best. The different priced instruments are of equally good tone—the price varying with the size and style of finish. The size, prices, etc., of these instruments can be learned particularly, by sending a stamp to Geo. A. Prince & Co., Buffalo, N. Y., for an illustrated descriptive circular. The instruments will, as a Premium, only be sent new directly from the factory at Buffalo, ready boxed, and without expense to the recipient, except for freight. Schools and churches can frequently combine their efforts and secure one of these instruments. This has been frequently done. See "N. B." under Premium No. 10.

Premium No. 9—Melodeon.

108 Subscribers at $1 each, (or **183** at 80 cents each) will entitle the person getting up the club to one of *Geo. A. Prince & Co.'s* **$60 Melodeons** (4½ octaves.) See No. 8

Premium No. 10—Melodeon.

90 Subscribers at $1 each, (or **130** at 80 cents each,) will entitle the person getting up the club to one of *Geo. A. Prince & Co.'s* **$50 Melodeons** (4 octaves.) See remarks above. **N. B.**—Higher or lower priced Melodeons will be given for larger lists, in the same proportion.

Premium No. 11—New Cyclopedia—A Splendid and Very Valuable Work.

96 Subscribers at $1 each, (or **140** at 80 cents each,) will entitle the person getting up the club to a set of *Appleton's* **New American Cyclopedia**, now in course of publication, consisting of *sixteen large volumes* of about **770** *pages each. This is a magnificent work for those using a whole library embracing every topic of human knowledge.* Fourteen volumes are now ready, and the remaining two will be furnished as soon as issued. We recommend it to every one, whether they procure it as a premium or not. The work is sold at $5 per volume, or $48 for the entire set. To no better purpose could any one devote the Winter evenings than in raising a club of subscribers to secure this for himself and family. Several schools have received it, through the combined efforts of the scholars in raising clubs of subscribers. Boys have also secured it by their individual efforts.

Premium No. 12—Best Dictionary.

18 Subscribers at $1 each, (or **40** at 80 cts. each,) will entitle the person getting up the club to a copy of the *large Pictorial Unabridged Edition of* **Worcester's Dictionary,** (Price $7.50.) This now stands confessedly the most valuable Standard Dictionary published. It contains **1854** pages of 3 columns each, giving the spelling and pronunciation, with the definitions, of every word in the English Language, and as a source of general information on all subjects, stands next to the Cyclopedia. The Dictionary can be called for at our Office, or be sent by Express or otherwise, to any part of the country.

Premiums Nos. 13 to 18—Back Volumes—A First-rate Library.

These premiums (13 to 18,) will enable any one to secure the previous excellent volumes of the *American Agriculturist*, as far back as Volume XVI. We have stereotype plates and can print any number desired of the English Volumes 16, 17, 18, 19, 20, and 21, and of the German Volumes 18, 19, 20, and 21. These will be sent in clean, new numbers, each volume by itself, with index and contents, **one volume** *at a time, postpaid.* The whole five can be taken together, or one or more copies of any particular volume be selected, as desired. They will be presented as to the table above, viz.: for **30** Subscribers at $1 each, (or 36 at 80 cents each,) we will present **six volumes.** For 16 Subscribers at $1 each, (or 20 at 80 cents each,) we will present **five volumes.**—For **13** Subscribers at $1 each, (or 26 at 80 cents each,) **four volumes.**—For **10** Subscribers at $1 each, (or 20 at 80 cents each,) **three volumes.**—For 7 Subscribers at $1 each, (or 14 at 80 cents each, **two volumes.**—For **10** Subscribers at 80 cents each, **one volume.**—Let every one selecting these premiums be careful to name *just which* back volumes are desired.

Premium No. 19—Best File for Agriculturist.

Jacobs' Portfolio File, made just to fit the *Agriculturist*—the name printed on. This is a leather cover or portfolio, so arranged that successive numbers of the paper can be inserted in a minute, and be properly preserved in book form when ready. When one volume is completed, the sheets can be removed and stitched, and a new volume inserted. A single cover will answer for a dozen successive volumes. It is a very handy and complete file for ready reference. Price $1, and the postage 23 cents. We will forward it, postpaid, to any one sending *eleven* subscribers, at the lowest club price, (80 cents each.)

Premium No. 20—Paints.

20 Subscribers at 80 cents each, will entitle the person getting up the club to an assortment of *Windsor & Newton's* **Water Color Cakes**—consisting of 12 colors, put up in a neat mahogany case, with brushes, etc. These Paints are imported from London, and are by all considered the best in the world. They are adapted to the finest work, and will make and appropriate present to any of our younger readers. They will be sent post-paid only where in the United States within 3000 miles.

Premium No. 21—Paints.

15 Subscribers at 80 cents each, will entitle the person getting up the club to an Assortment of *Osborne & Hodgkinson's* **Water Color Paints,** consisting of 24 colors or shades, put up in a neat mahogany case, with brushes, etc. These are of American manufacture, and though not so fine as the above, will answer for ordinary practice by children or beginners, and for common sketching. Sent same as No. 20.

Premiums Nos. 23 to 26.

We have not room left to describe these particularly, this month. The Cylinder Plow was described in this journal last year. It is undoubtedly a great improvement. The Eagle Plow is well known, and so is the Hay and Straw Cutter, and the Steel-toothed Cultivator, one of the most useful implements on the farm. The Lard and Wine Press is a very convenient machine for pressing out lard or tallow, the juice of grapes, currants, berries, &c. For the prices, and subscribers required, see the table above.

Reports on Crops, August 10, 1862.

(*See General Remarks and Reports on Special Crops on page* 264.)

NOTE TO REPORTERS.—It is very important that a large number of the reports be mailed earlier than heretofore. It is useless to put two rows of figures, *for we are* obliged to average them after each month. It is also perplexing to have the words *fair, good, pretty good, poor*, etc., used instead of figures. After a crop is harvested, please estimate it, and mark figures as usual.

EXPLANATIONS TO THE READER. (Full details are given on the Blank Forms furnished to Reporters.)

The First Column gives the Counties from which the reports come. In many cases the territory reported upon extends over adjacent counties, and the figures apply to a larger territory than the county name indicates. It is not sometimes to single townships only.

The Second Column gives the number of persons in each county or locality, the average of whose opinions are embraced in the single rows of figures, standing opposite in the same line. In several cases a whole County is represented by an officer of the Agricultural Society, who gives the summary of reports from assistants in each of the towns. An indication that a large but indefinite number of persons joined in making the report.

The Third Column gives the names of the persons who received and distributed blanks, and collected and forwarded returns.

☞ *In all the reports the numeral* **10** *is taken as the standard for comparison*, thus :

Column A—10 means that the weather for a month previous to the date of the report was about as good as the average for other years, that is for growing crops and for general farm operations. Figures above or below **10** indicate the comparative propitiousness or unfavorableness of the weather.

Columns—B—E—H—In these **10** indicates that the amount of surface growing is about the same as *last year*. Each figure (or unit) above **10** means a tenth more of surface, and each unit below **10**, means one-tenth less. Thus, **5** means one-half of average surface—**15** means one and a half—**20** means double, and so on.

Columns C—F—I—L—N—P—S—In these columns **10** means that the average surface sown or planted or growing is about the same as the average for five years past. Each unit above or below **10** stands for an increase or decrease of one-tenth in the surface.

Columns D—G—K—M—O—R—T—U—V—In these columns **10** means that the *condition* and *prospect* at the date of Report, indicated an *average yield per acre*. Here also each unit above or below ten indicates the prospect of a yield a tenth above or below the average ; thus, a half crop is indicated by **5**—a double crop by **20.** Some report fruit prospects at **100** to **150**, meaning that the promise is for ten to fifteen times the average.

Blanks left in a column indicate that little or none of the crop is grown, or that it is too early to report upon it, or that the reporter could not estimate satisfactorily to himself. No reports have been received from some whose names are in the list, and who furnished reports last month.—For commeuts and reports on other crops see page 264.

The business in Breadstuffs, during the past month, has been vigorous on the whole, and quite encouraging. The fluctuations in the value of gold, and of Sterling Exchange Bills, have been generally unfavorable to the export trade ; yet extensive foreign orders have been received and executed, giving a very satisfactory exhibit in the Custom House returns, of the month's shipments of Flour and Grain to Europe, especially to Great Britain. Private letters from the Old World are explicit in their representations of the deficiency of the crops, and the probable wants of Western Europe, making it reasonably certain that our own country will be called upon to furnish liberal supplies, and that, too, at prices, which (thanks to a benign Providence and the unusual fullness of our harvests) will enable us to defy all competition. The rate of exchange is still decidedly in our favor ; while it is as decidedly against Russia, our only serious rival in the production of food, for export ; and this circumstance gives us an important advantage. Our receipts from the interior continue on a large scale ; but much of the grain coming forward is damp, dirty, and unfit to ship, and on this account, the principal foreign buyers are somewhat embarrassed in the execution of orders for desirable lots of Wheat and Corn, particularly the former. There is very little other than mixed Corn arriving—yellow and white being quite scarce. The condition of the Rye now coming to market, especially from the North-west, is very poor indeed, and shippers are reluctant to make free purchases. Barley is quite nominal in value, as there is no demand for it. The market generally, in fact, closes stiffly at the improved prices quoted in our accompanying tables, the tendency being towards a higher range. The last steamer brought somewhat more favorable *weather* reports from England and France ; but the letters received in the same mail, can not be said to present any more encouragement in regard to the probable yield of the harvests in those countries....Cotton has been less active, and has been depressed, the market closing heavily. The receipts have been comparatively liberal, and buyers have been less eager to purchase in advance of their actual wants....There has been rather more activity in Provisions at slightly improved prices for the principal articles....Rice has been in moderate supply and demand ; the bulk of the sales being composed of East India, in the absence of Carolina, which has been out of market for some weeks....The inquiry for Hay and Hops has been good, for the season, and prices of the former have advanced....Tobacco has been in fair request at firmer rates....Wool has been freely purchased, chiefly by manufacturers, at higher quotations, the market closing quite buoyantly, particularly for domestic, the receipts of which have been very moderate, not only here, but at all the sea-board markets....The transactions in other agricultural products have been on a moderate scale. The table of prices show the changes and present rates.

N. Y. Live Stock Markets.—THE CATTLE MARKETS have been abundantly supplied during the past five weeks, the average being 4,535 per week. July 22, the large number of 5,582 were offered. Prices declined ¼c., and 250 were left unsold.—July 29, there were 3,887 head, with no change in prices. August 5, receipts 4,629 head, and ½c. decline. August 12, 4,448 head, and a further decline of ¼c. To-day, (August 19.) with 4,130 bullocks on sale, trade has been very lively, and all the cattle were sold at an early hour at ½c. advance. or 8¼c. @8½c. ℔ lb., estimated dressed weight, for prime beeves ; 7¾c.@8c. for good ; 6½c.@7c. for poor ; average 7½c.

Veal Calves.—Receipts are light, (530 per week,) but sufficient for the demand of hot Summer weather, though they are ½c. higher than they were 5 weeks ago. The best calves sell at 5½c. ℔ lb live weight, and ordinary veals 4c.@4½c.

Sheep and Lambs.—Receeipts are on the increase, but do not keep pace with the demand, and prices have gradually advanced during the past few weeks. Good sheep now sell at prices equivalent to 4½c. ℔ lb., live weight, and fat lambs at 5c.@5½c. The weekly average has been 11,176 since last reported.

Live Hogs have been coming forward very freely, the average for the past 5 weeks amounting to 12,040 ℔ week. Prices have been pretty good, except for week ending August 12th, when near 15,000 hogs produced a glut, and carried prices to 3¾c.@3½c- for fat corn-fed hogs. They are now worth 3½c.@3¾c. ℔ lb., live weight, and a good demand has used up all the stock.

Thermometer at 6 A. M., New-York.

[Observations carefully made upon a standard Thermometer (Fahrenheit.)—*r* indicates rain—*s*, snow.]

The Weather has, for the most part, been warm, with just sufficient rain to keep vegetation in a good healthy and rapid-growing condition. The hay and grain crops were gathered in good order, and corn and other field and orchard crops are coming on finely, with every prospect of a bountiful harvest, as shown by our crop reports, page 282. OUR DAILY NOTES, condensed, read :——July 19, clear, fine—20, cloudy, light rain P. M.—21, 22, cloudy—23, cloudy, heavy N. E. rain-storm at night, continuing lightly 24th—25th, cloudy A. M., clear P. An American Exhibition
OF
Pumpkins, Squashes, and Ornamental Gourds.

There will be a Public Exhibition of **Pumpkins, Squashes, and Ornamental Gourds,** at the office of the *American Agriculturist*, 41 Park Row, New York City, opening on Wednesday, Nov. 5th, 1862, at which the following prizes will be paid by the Publisher, upon the official award of competent Committees.

CASH PREMIUMS.

I.	For the *Heaviest* Pumpkin or Squash...	$20.00
II.	For the 2nd do. do.......	10.00
III.	For the 3d do. do......	5.00
IV.	For the Best do. do. for cooking..	10.00
V.	For the 2nd Best do. do. do. ...	5.00
VI.	For the largest yield on a single Vine.*...	10.00
VII.	For the 2nd do. do. *..	5.00
VIII.	For the largest and finest collection of Fancy or Ornamental Gourds*......	10.00
IX.	For the 2nd do. do. *......	5.00

* All to be grown by one person and to be accompanied by an affirmed statement from the grower, and two disinterested persons who assist in gathering the specimens.

Note 1.—The specimens receiving the Prizes will remain on Public Exhibition at the pleasure of the Publisher who offers the prizes. The other specimens will be subject to the order of the exhibitors, or they will be sold at Auction or otherwise disposed of, for their benefit.

Note 2.—All Exhibitors must notify us of their intentions by Oct. 10th, and deliver specimens for competition on or before Nov. 3d. Specimens to be delivered free of charge.

$100 IN PREMIUMS
FOR
NORTHERN GROWN COTTON.
Another Interesting Exhibition
AT THE OFFICE OF THE
American Agriculturist, 41 Park-Row.

One Hundred Dollars are offered for the best five specimens of cotton grown above latitudes 38° and 40°, the present year, as follows : For 10 lbs., (unginned,) grown north of latitude 40°, 1st prem., $30 ; 2d $20 ; 3d $10. For 10 lbs., (unginned,) grown north of latitude 38° and south of 40°, 1st prem., $25 ; 2d $15. The samples on which premiums shall have been awarded, will be retained on our exhibition tables for the inspection of the public. All others will be subject to the direction of the exhibitors, at the close of the Exhibition. For particulars see February number *American Agriculturist*, page 64.

The Postage on the Agriculturist is positively only Six Cents a Year.

We hear that several Post Masters are charging 12, 18, 36, and even 72 cents a year on the *Agriculturist*. This is wrong. The law expressly says that a Periodical issued at stated periods, and not weighing over 3 ounces avoirdupois, shall be charged *one cent* per number, and only *half* this sum if paid quarterly in advance. The paper for the *Agriculturist* is purposely manufactured so that it shall weigh a little *less than three ounces.*

American Agriculturist in German.

The AMERICAN AGRICULTURIST is published in both the English and German Languages. Both Editions are of the same size, and contain, as nearly as possible, the same Articles and Illustrations. The German Edition is furnished at the same rates as the English, singly or in clubs. A club may be part English, and part German.

Bound Volumes—Binding—Covers.

We have complete sets of Vols. 16, 17, 18, 19, and 20, both unbound, and bound separately in neat covers with gilt lettered backs.

PRICES AT THE OFFICE.

Volumes 16, 17, 18, 19, and 20, *unbound*..............$1,00 each.
Volumes 16, 17, 18, 19, and 20, *bound*..................$1.50 each.

PRICES WHEN SENT POST-PAID BY MAIL.
(*They can not go unpaid.*)

Volumes 16, 17, 18, 19, or 20, *unbound*..............$1.12 each.
Volumes 16, 17, 18, 19, or 20, *bound*..................$2.00 each.

BINDING.—Sets of numbers brought to the office will be bound up neatly (in our regular style of binding the *Agriculturist*) for 50 cents a volume.

PREPARED COVERS.—Covers for binding, neatly made, with title, etc., gilt upon the back, ready for the insertion of the sheets by any bookbinder; can be furnished for Vols. 12, to 20 inclusive, at 25 cents per cover. *Covers can not go by mail.*

Advertisements.

Advertisements to be sure of insertion must be received at latest by the 15th of the preceding month.

TERMS—(invariably cash before insertion):

FOR THE ENGLISH EDITION ONLY.

Fifty cents per line of *nonpa*reil for each insertion.
One whole column (145 lines), or more, $20 per column.
☞ Business Notices, *Eighty cents* per line of space.

Flushing Institute,
A Boarding School for Boys at Flushing, L. I.
E. A. FAIRCHILD.

Hop-Yard and Farm for Sale.
A beautifully situated and highly cultivated farm, with extensive Hop-Yard, fine garden and orchard, barns, stalls, icehouse, and a fine residence, 22 miles from Chicago, Ill., for sale cheap. Enquire of KOUP, SATTLEE & CO.,
38 Broad-st., New-York.

TEETH
UPON ALLEN'S SYSTEM
CAN BE OBTAINED AT
22 Bond-st., New-York.
By this method the TEETH, GUMS, ROOF, and RUGÆ of the MOUTH are so faithfully represented, reflecting those delicate tints, shades, and forms peculiar to the natural organs, thus concealing from the observer the human agency in forming them. This we do positively accomplish, as evidenced by our numerous patrons. The natural expression of the mouth, and original contour of the face can also be restored, while refunwasting the sinking cheek.
A descriptive pamphlet may be obtained by addressing DRS. J. ALLEN & SON, as above.

GLASS FRUIT JARS WITH A SHOULDER.
Quart Jars with Corks and Tin Covers, $1.50 per Dozen.
Flat Jars do. 1.10 do.
THE AQUARIUS. Price $8.
HARVEY B. LANE,

Treatise on Sorghum Wine,
WITH
A RECIPE FOR MAKING IT,

Now offered for sale. I will dispose of Individual, Manufacturer's, County and State Rights.

Sorghum wine has taken the country by surprise, not only on account of its production from this plant, but of its superior quality. It has been awarded at the State Sorghum Convention of Ohio, January 7, 1863, and highly commended. It has been exhibited to wine connoisseurs in Columbus, Cincinnati, Springfield, Cleveland, New-York, Philadelphia, Baltimore and Washington. It has not only surprised them but received their unqualified commendation. It has been used by Physicians in cases of sickness with entire satisfaction, because of its purity and healthfulness. And dyspeptics, some of whom have been restored to health by the use of a few gallons, have given harmonious testimony of its beneficial effects.

RECOMMENDATIONS.

From Hon. William B. Hubbard, of Columbus, O., President U. S. Agricultural Society.

Columbus, March 31, 1862.

Rev. A. Myers—Dear Sir: The sample of Sorghum Wine, left by you with me, has been submitted to several good wine judges, who have visited my house, and, without exception, has met with decided commendation. Most of them pronounce the aroma, or fragrance, of your Wine that of the Sherry, the minority that of the Madeira. It is certainly a fair wine, and deserves, and no doubt from the ease and cheapness of its manufacture to become an item of note to the manufacturer and cultivator. Yours truly,

W. B. HUBBARD.

From Mr. D. M. Cook, of Mansfield, O., Patentee of Cook's Portable Evaporator.

Mansfield, O., March 15, 1862.

Rev. A. Myers—Dear Sir: I have used your Wine, made from the Sorghum juice, and I have no hesitation in the fact that your Sorghum Wine is most delicious, and that it would be difficult to distinguish it from the best Madeira Wines.

Hoping that you will not fail to introduce your work on Sorghum, as also your Wine to the public, I am truly your most obedient, D. M. COOK.

THIS WINE IS A MILD STIMULANT AND STRONG TONIC.

1. An *Individual Right* embraces the privilege of manufacturing all wine desires for his own family. Price $100.

2. A *Manufacturer's Right* embraces the privilege to manufacture all a manufacturer of Sorghum Syrup can while he is manufacturing Syrup, from the vintage of his own farm, and imbrace Syrup for his own use and for sale. Price from $5.00 to $25.00.

3. A *Township, County or State Right* embraces the exclusive privilege of manufacturing and selling Recipes in said limits.

REFERENCES.—As a guarantee of honesty and ability to perform all I agree, I refer to the President and Professors of Wittenberg College, Springfield, O.; any of the citizens of this city, or Bucyrus, O., and all the English Lutheran Ministers in the State of Ohio, especially those of the Miami and Wittenberg Synods.

Persons desiring the use of this recipe, and indicating the privilege they desire, and sending the amounts to me by mail, or when the sum exceeds $5.00, by Express or draft, will receive by return mail receipt for the right, and about the first of Sept. the recipe. Every subscriber will be required to sign an obligation of secrecy which they will receive with the certificate of right to be returned to me when signed. This is required to secure to me my rights in the matter. Honest men will not hesitate to comply, and with dishonest ones I wish to have no dealings. Persons well known in my community making up a club of Ten or more subscribers will be suitably rewarded. Address A. MYERS,

Springfield, Ohio.

ONION CULTURE—Third (new) Edition.

This work comprises in 32 pages all the particulars for successful Onion Culture, from Selection of Seed to Marketing the Crop—being the practical directions given by *seventeen experienced* Onion Growers, residing in different parts of the country. Price 25 cents (or 7 stamps), sent post-paid. Address Publisher of *Agriculturist*.

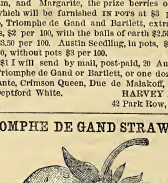
TRIOMPHE DE GAND STRAWBERRY.



This unrivalled strawberry has fully sustained its reputation the present season. Our stock of GENUINE plants is unequalled any where.

Send for Circular.

J. KNOX,
Box 155, Pittsburgh, Pa.

New and Splendid Varieties of Strawberries.

Empress Eugenie, Margarite, Prince Frederick William, and Victory.

The last is an American Seedling. Fruit of immense size. The other three are the prize varieties of Europe for 1861. Fruit of extraordinary size, weighing from one to two ounces each. The above at $2.00 per dozen, or the four, one dozen each, for $7.00.

The following are new and fine varieties, La Constante, Wizard of the North, Wonderful, Oscar, Duc de Berband, Prince of Wales, Honneur de Belgique, Filbert Pine, Crimson Queen, Prince Imperial, Surpass Triomphe, Deptford White, and Austin Seedling, at $1.00 per dozen; a selection of six for $4.00, or the thirteen varieties for $7.00.

La Constante can be furnished by the hundred for $4.00 This magnificent berry, after two years trial, has proved to be of great value as a market berry. Fruit very large, fine color, and very productive. A special prize was awarded this variety at the exhibition in Boston last year.

Triomphe de Gand, Bartlett, Downer's Prolific, Jenny Lind, True Chili, and Athlete, at $1.50 per hundred, or $10.00 per thousand. Downer's Prolific is a fine market berry; it is more productive than the Wilson. Fruit large and a beautiful scarlet color.

Great Austin Shaker Seedling, 50 plants $1.00; $2 per 100; $15.00 per 1000. Not less than one dozen sold of any variety. All orders addressed to

WM. S. CARPENTER, 329 Greenwich-st., N. Y.

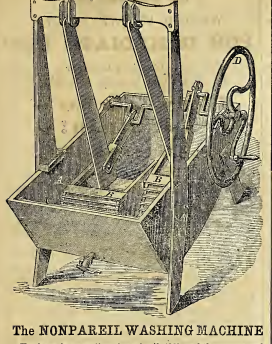
will send their priced Catalogues to applicants who enclose stamps. Select Strawberries, 200 varieties, comprising every estimable kind, at lowest prices. Grapes and all other Small Fruits. Bulbous Roots and Peonies. Fruit and Ornamental Trees, Flowering Plants, &c.



The NONPAREIL WASHING MACHINE

Has been in operation since April, 1861, and the severe and varied tests, to which it has been subjected, in country and city families and laundries, demonstrate that two-thirds the labor and time, and half the soap required in hand washing, are saved by its use; and no injury can possibly result to the most delicate fabric from its action. It is a squeezing machine, and it washes with equal effectiveness a cambric handkerchief, or a bed quilt.

The machine is carefully made of the best materials, and its strength and durability will be found in keeping with its extreme simplicity. There is nothing in its construction liable to get out of order; and no training is required to enable the least skilful person to work it satisfactorily. A girl twelve years old can operate it.

Three sizes of family machines are made, their capacity being about the bulk of five, eight, and twelve shirts respectively. Prices: No. 1, $10; No. 2, $14; No. 3, $17.

Machines to go by Power are manufactured for the use of Hotels and Laundries.

Circulars, giving full descriptions, will be forwarded by OAKLEY & KEATING, 73 South-st., New-York.

OUR "EXCELSIOR BURR STONE MILLS," AND ANTI-FRICTION HORSE POWERS.

Have taken the HIGHEST PREMIUMS WHEREVER EXHIBITED; NINE FIRST PREMIUMS being received from WESTERN STATE FAIRS last year.

THE MILL may be driven by *horse, water,* or *steam power,* does its work equally as well as the best flat stone mills in milling establishments, and requires but *one-half the power* to do the same amount of work. They are made in the best manner, and will last *thirty years,* and cost *nothing for repairs.*

THE HORSE-POWER runs upon iron balls, and requires but TWO AND A HALF POUNDS DRAUGHT to keep it in motion. With the same number of horses it will do TWENTY-FIVE PER CENT more work than ANY OTHER POWER IN USE.

Price of Power for 1, 2, 3, or 4 horses.....$125
Price of Power for 1 to 8 horses.....175

THE SIZE POWER WILL DRIVE ANY THRASHING MACHINE, and was awarded the first premiums OVER THE BEST 8 AND 10 HORSE POWERS at the State Fairs last Fall.

☞ EVERY MACHINE IS GUARANTEED TO GIVE SATISFACTION, OR THE MONEY WILL BE REFUNDED. ☜

Lady Volunteers!

Wanted a hundred regiments of them, to go to Grocery Stores and ask for and insist upon having, as a necessity in domestic economy,

Pyle's Saleratus and O. K. Soap,

Thus necessitate dealers to keep before the public, and for the good of all, the two best articles of the kind ever invented.

The Aquarius.

The Aquarius.

A NEW and most invaluable article for which the Subscribers have received LETTERS PATENT from the United States, and is offered to the public as the most complete and perfect hand apparatus ever invented for throwing water.

It will throw about EIGHT GALLONS of water per minute fifty feet high with the power of only one hand applied. Being a most invaluable article for WASHING WINDOWS, WASHING CARRIAGES, WATERING GARDENS, SPRINKLING STREETS, Throwing on Liquid COMPOSITION, such as WHALE OIL SOAP SUDS, TOBACCO WATER, &c.; for DESTROYING INSECTS on TREES, ROSES, and other PLANTS, PUMPING WATER from the HOLDS of VESSELS, SMALL BOATS, CELLARS, &c.; WETTING SAILS, WASHING DECKS, STARTING AGUE DUCTS.—Also, for INVALIDS it is a most valuable SPRAY or SHOWER BATH. It is most invaluable for EXTINGUISHING FIRES, and for WETTING ROOFS near Fires. In hundreds of cases GREAT CONFLAGRATIONS might be avoided by the use of this simple apparatus. It is so portable that it can be used where no other article could be readily brought to bear.

All who have seen and used the article speak in the most unbounded terms of praise and commendation of its valuable qualities and perfect and BEAUTIFUL OPERATION. No DWELLING, FACTORY, STORE, SCHOOL HOUSE, STABLE, BARN, BOX HOUSE, VESSEL, or BOAT, should be without this invaluable WATER THROWER.

It is very COMPACT and WEIGHS ONLY about EIGHT POUNDS.

☞ Orders respectfully solicited.

Tarrytown, Westchester Co., N. Y.,
Or Newark, N. J.

LODI PHOSPHATE.

Composed of raw bones dissolved in sulphuric acid, night soil, guano, and wood ashes, made by the

Lodi Manufacturing Co.

expressly for Winter Grain and Grass Lands. This article will be warranted to contain no other material than those mentioned above, is pronounced by the very best manure in market from its composition, and will be sold at the low price of $45 per ton, packed in barrels of 200 lbs. each, net weight, delivered free on board of vessel or railroad in New-York City.

Pondrette of first quality for sale at usual rates. Apply to
THE LODI MANUFACTURING CO.,
60 Cortlandt-st., New-York.

PROVIDENCE COMPANY'S CONCENTRATED BONE FERTILIZER.

The best and cheapest Fertilizer for
CORN, GRASS,
GRAIN, BUCKWHEAT,
TURNIPS, CARROTS, &c.

It acts quick, enriches the soil, and insures large crops. It is packed in barrels and sold at the following prices, viz.: for one barrel, $2; two, $3.50; three, $5; four, $6.50; five, $8; six, $9.50; seven and over, $1.50 per barrel.

GRIFFING, BROTHER & CO.,
Sole Agents for the United States.
No. 60 Courtlandt-st., New-York.

FERTILIZERS.

COE'S SUPERPHOSPHATE OF LIME.
PURE GROUND BONE.
MANIPULATED GUANO.
NO. 1 PERUVIAN GUANO.
PONDRETTE, LAND PLASTER, &c.
R. H. ALLEN & CO., 189 and 191 Water-st., New-York.

TO FARMERS.

We have arranged for a large supply of
PURE GROUND BONES,
the cheapest and best fertilizer that a farmer can use. We are selling at the low prices of $30 to $35 per ton, packed in good flour barrels, free of charge.

CLUBS

Can at any time be increased, by remitting for each addition, the price paid by the original members—provided the subscriptions all date back to the same starting point. The back numbers will of course be sent to added names.

HO! FOR A
'Vigorous Campaign.'

Though not liable to military duty, we have sent a good substitute to the war in behalf of our country, and a part of our usual office force have also gone. But we have supplied all deficiencies, with "exempts"—good men and true—and as Commander of the regiment we purpose to wage a vigorous war upon ignorance in general, and upon poor, non-paying crops in particular. Nearly half the agricultural papers have succumbed, or are about yielding to the pressure of the times, but thanks to the kind appreciation and the efforts on the part of our readers, the *Agriculturist* is still as prosperous as ever. It will continue on in its old course, but with sundry improvements—such improvements as will, we trust, make it more acceptable and more useful than ever.

Many more of our present patrons will of course go to the war, and we desire to ask the aid of those who do not, in securing new names to fill up the subscription lists. We mean to make the paper eminently *useful* to every one who cultivates a rod of ground, as well as to every housekeeper, and to every child. To those who get up clubs, we offer the best remuneration we can. See list of valuable premiums on page 281.

We desire an ARMY of new readers to *see* this journal before January, for each one who does so, will, we think, help secure *others* to begin the next volume.

Therefore

We offer the rest of this year *free*, that is, **15 Months** for the price of 12, to every *new* subscriber for 1863 (Vol. 22, complete) whose name is received now, or before September 30th.—[Very distant subscribers will have time after Sept. 30, to respond to this offer.]

N. B.—The above extra 3 months are offered to *all* new subscribers received this month—single, or in clubs, or on premium lists, or from Agricultural Societies.

3 Month's Papers Free.

(See above.)

For September Only.

WHO WANTS
GOOD STRAWBERRIES
FREE?

Here is a chance to get some of the best plants **NOW.** There are several new sorts that have proved good in a single locality, and which *may* prove to be superior when transferred elsewhere. But the **Triumph de Gand** has turned out well almost everywhere throughout the entire country. Indeed, no other variety has given such universal satisfaction, as a free grower, an **abundant bearer,** and a large **delicious berry,** good for the **table** and for **market.** We have had a large stock of excellent plants grown specially to distribute among our subscribers, as Premiums. A portion of these have been already called for, and will be sent out as soon as the weather will permit. We shall have a few thousands more, which will be distributed during September, if called for early, on the following

CONDITIONS:

To any person forwarding now, (or before Sept. 25,) **One** new Subscriber to the *Agriculturist* for 1863, including also the rest of this year, at $1, we will send, post-paid, **Ten Plants** of the **Triumph de Gand Strawberry.**——For **Two** Subscribers, as above, **Twenty-five Plants.**——For **Three** or **More** Subscribers, as above, **Fifteen Plants** for **each name.**

☞ The plants will be put up in the best manner, and sent free of expense. They will start into growth this Fall, and yield some fruit next season, and also plants enough to supply one or more **large** gardens. With a little care, 10 plants may be multiplied to many hundreds in less than a year from the first setting out. Get the plants **now,** and save a whole year in time.

For September Only.

WANTED BY EVERYBODY!!

FOR IMMEDIATE USE!

And can be obtained by Every Subscriber to the American Agriculturist by a few minutes' work.

Lloyd's Great Map of Virginia!

Size 30 by 50 Inches,

Or more than **TEN SQUARE FEET** of surface, giving even the smallest towns and localities.

The greatest War movements of the present age are transpiring and about to transpire in Virginia. The above Map, beautifully colored, shows every town, stream, mountain and hill, so that all the movements of the Armies can be readily followed. To meet the demand at this juncture, the Publisher of the *American Agriculturist* has arranged to send a copy of this Map (*post-paid*), to every one now sending in a subscription for 1863, (Vol. XXII) at $1. (New subscribers for next year will also receive the remaining three numbers of the *Agriculturist* for this year, without extra charge.)

This Map is engraved from the costly surveys made by the State of Virginia, which fell into the hands of the Union soldiers. It will be of great value in the future, as well as in the present time. It is alone really worth more than the dollar, but having been engraved by a new process, and worked upon a power press instead of by the usual slow method, it is printed so cheaply that the Publisher is enabled to make the above liberal offer.

Or, Instead of the Above,

A large Map of the Southern States, including Missouri, Kentucky, Virginia, Maryland, and Delaware, and all South of them. The States are Colored, the Counties all indicated, together with the towns, rivers, etc., etc. This Map is 3¼ by 4¾ feet, and contains about **15** square feet of surface. It is specially valuable at this time.

For Two Subscribers at $1 Each,

We will send (post-paid,) Lloyd's great MAP of all the

United States, Canadas & New Brunswick,

with every County colored separately.

This is a splendid, large Map, 3½ by 4½ feet, or nearly **15** square feet of surface. It is very valuable at any time, and especially now, when every one is daily studying the geography of our country. ☞ These Maps of course exclude all other premiums on the *same name*, and are *only sold for September*, except to persons too distant to send in this month.

American Agriculturist.

For the Farm, Garden, and Household.

A THOROUGH-GOING, RELIABLE, and PRACTICAL Journal, devoted to the different departments of SOIL CULTURE—such as growing FIELD CROPS; ORCHARD and GARDEN FRUITS; GARDEN VEGETABLES and FLOWERS; TREES, PLANTS, and FLOWERS for the LAWN or YARD; care of DOMESTIC ANIMALS, &c., &c., and to HOUSEHOLD LABORS. It has also an interesting and instructive department for CHILDREN and YOUTH.

A full CALENDAR OF OPERATIONS every month.

THREE to FOUR HUNDRED, or more, ILLUSTRATIVE ENGRAVINGS appear in each volume.

Over TWELVE HUNDRED PLAIN, PRACTICAL, instructive articles and useful items, are given every year.

The Editors and Contributors are all PRACTICAL WORKING MEN.

The teachings of the AGRICULTURIST *are confined to no State or Territory, but are adapted to the wants of all sections of the country—it is, as its name indicates, for the whole* AMERICAN CONTINENT.

TERMS—INVARIABLY IN ADVANCE,
(For either the English or German Edition.)

One copy, one year.....	$1 00
Six copies, one year.....	5 00

Ten or more copies one year.....80 cents each.

☞ Add to the above rates: Postage to Canada, 6 cents; to England and France, 24 cents; to Germany, 36 cents.

Postage anywhere in the United States and Territories must be paid by the subscriber, and is *only six cents a year*, if paid in advance at the office where received.

All business and other communications should be addressed to the Editor and Proprietor,

ORANGE JUDD, 41 Park-Row, New York City.

FROM THE STEAM PRESSES OF JOHN A. GRAY.

AMERICAN AGRICULTURIST,

Farm, Garden, and Household.

"AGRICULTURE IS THE MOST HEALTHFUL, MOST USEFUL, AND MOST NOBLE EMPLOYMENT OF MAN."—WASHINGTON.

ORANGE JUDD, A.M., EDITOR AND PROPRIETOR. Office, 41 Park Row, (Times Buildings.)

ESTABLISHED IN 1842. Published both in English and German.

$1.00 PER ANNUM, IN ADVANCE. SINGLE NUMBER, 10 CENTS. For Contents, Terms, etc., see page 320.

VOLUME XXI—No. 10. NEW-YORK, OCTOBER, 1862. NEW SERIES—No. 189.

Entered according to act of Congress in the year 1862, by ORANGE JUDD, in the Clerk's Office of the District Court of the United States for the Southern District of New-York. ☞ Other Journals are invited to copy desirable articles freely, if each article be credited to *American Agriculturist.*

☞ See the Last Page, this month.

October.

"What though the fruit tree rival not the worth
Of Artcanian products? Yet her freight
Is not contemned; yet her wide branching arms
Best screen thy mansion from the fervent day
Adverse to life; the wintry hurricanes
In vain employ their roar; her trunk unmoved
Breaks the strong onset, and controls their rage.
Chiefly the Roxbury, whose large increase,
Annual, in sumptuous banquets claims applause.
Thrice acceptable beverage! could but art
Subdue the floating lee, Pomona's self
Would dread thy praise, and shun the dubious strife."
PHILIPS.

If the apple is the fruit for the million, the pear is the fruit for the amateur. If the one should be planted in large orchards, the other should find its home in the garden and fruit yard about the dwelling. There is a reason for the enthusiasm with which this fruit is regarded by all pomologists, aside from the profits which it yields to nurserymen and to those who grow it for market. Though something called pears were known to the ancients, the delicious dessert fruit, now known by that name, is a modern 'invention.' We read of pears in Virgil and Pliny, and other old Roman writers. What the fruit was, is readily inferred from the confession of the latter author, "all pears whatsoever are but a heavy meat, unless they are well boiled or baked." It was not until the seventeenth century, that pears made much progress. What that progress is any one can decide, who tastes a crabbed perry and a Seckel, and compares the juices. If the one gripes his throat and compels wry faces, the other leaves behind an aromatic sweetness, suggestive of the food of the gods. A fruit so capable of improvement in size and quality, very naturally awakens the enthusiasm of cultivators—orchardists and amateurs. It unquestionably requires more skill, at least in the older States, to grow good pears, than good apples. The latter will flourish with little care after being once established. The former, especially if dwarfed upon the quince, must have a good soil and skillful cultivation to make it reward the planter. It pays abundantly for generous feeding and skillful handling, and perhaps it is owing in part to this fact that it is the special pet of some of our distinguished pomologists. It heralds the fame of the fruit grower, and a man becomes distinguished according to the number of varieties and the size of the specimens of this fruit which he exhibits at the fairs, as in the olden time he became famous according as he lifted up the ax against the thick trees of the wood. Tree-slaying has become infamous, and he that would shine in fairs in modern times, must not only know how to select, but how to plant and prune, and feed pear trees.

The rareness of fine varieties of this fruit has made it an object of special desire to the cultivated and refined. It is somewhat a badge of social distinction, like diamonds and rare wines. Not one family in a thousand in this land of plenty has ever had a dish of this fruit at its best estate served for dessert. Virgalieus and Seckels are even rarer than wine, though our nurseries have sent forth trees by the thousand and tens of thousands, for the last score of years. Every genteel family living pernanently in the country, or residing there for the Summer, plants dwarf and standard pears of approved varieties. Madam covets the fruit dish loaded with Bartletts, or Flemish Beauties, as she would splendid silver for her table. The silver is much more common at dinner than fine pears. It is a social triumph when our dwarfs are a success, and the pets of the fruit yard furnish a supply of melting pears for Summer guests.

Whatever the cause, the pear has a popularity beyond any other of the larger fruits. Downing glories in it, in prose more eloquent than song, and the discussions of highest interest in the meetings of our Pomological Societies are upon this fruit. With failures more numerous than successes, in planting dwarfs, people keep planting them, determining with resolute Anglo Saxon courage to educate themselves into success. In its natural state, the pear is more hardy and long lived than the apple, reaching in rare cases the age of four hundred years. Though an exotic in this country, it is probably as vigorous and healthful here as in its native clime. The Stuyvesant pear tree still fruitful after two hundred years of bearing, is a good witness of the hardiness and the long life of this fruit.

The causes of failure, especially with the dwarfs, are easily pointed out. More of them are from improper planting and from neglect than from all other causes. They are often set out upon land too poor to nourish them. They live, but make no new wood. They are thrown prematurely into bearing by transplanting, and the cultivator, pleased with the early fruitfulness, lets them bear all they will. The whole force of the tree is thrown into fruit, and after a few years it is exhausted and dies. Sometimes the tree is planted too high, the quince stock being three or four inches above ground, instead of beneath, as it should be. The borer attacks the quince, and if neglected, soon destroys it. We have frequently seen them planted in green sward, the grass taking all the strength of the soil, and the trees looking much like walking canes, years after planting. Sometimes they are not manured at all. The demand is for abundant compost manuring every fall. Again, they are trimmed up as high as one's head, before they are suffered to make limbs. With the comparatively weak roots of the quince, this gives the wiuds a great purchase upon the tops of the trees, and unless they are staked up they are soon broken off. The demand is for limbs near the ground, forming a pyramidal base, to rise not more than a foot a year until the structure gets beyond the reach of the pruning knife.

The well-trained dwarf is a creation of human skill, as much so as any work of the architect. If a man does not know how to build, or can not take the time to learn, let him eschew dwarfs as too small business for him. Standards are more easily reared and much longer lived. They pay quite as well for good soil and cultivation. They are much longer in coming into bearing, some varieties requiring fifteen years of good cultivation before they will give forth their treasures. But when once they break into fruit, they make up for lost time, and are a fountain of delight to the fruit grower, for the rest of his life, and a monument to his memory when he is dead. As the season of planting again returns, we throw out these few hints in regard to the favorite fruit of modern times. Notwithstanding the war and the duty of thirty per cent., pear trees will continue to be imported and planted. Let the work be well done.

THE WAR AND FEMALE FARMERS.—We are constantly hearing, especially from the West, of instances where farmers have patriotically exchanged the plow for the musket, encouraged to do so by their wives who have cheerfully assumed the care and responsibility of conducting the labors of the fields during their absence. Such noble women deserve not only the good will of their neighbors, but their kindest attention. Let them want in nothing of friendly advice, and oversight against imposition in the sale of their produce, and in the purchase of supplies. See to it that they have the aid of a "husking bee," a wood-cutting gathering, and any other assistance that can be rendered to them. Farmers' Clubs should take such cases under their special care. Our aged correspondent, Diogenes, has a talk about a woman farmer on another page of this month's *American Agriculturist.*

Calendar of Operations for Oct., 1862.

[A glance over notes like the following will generally call to mind some piece of work that would otherwise be forgotten or neglected. The remarks are more especially adapted to places between 38° to 42°, but will be equally applicable further North and South, by allowing for latitude.]

Farm.

But few days will now intervene before the "Advance Guard," of stern Winter will make a descent upon us, and Col. Frost and his Snow Brigade will make fearful "havoc" among the stores of those unprepared for the "raid." Farmers must marshal their forces at once and exercise a watchful care against this invader. They must volunteer their efforts, and not wait to be driven or "drafted" into the contest. Remissness is sure to lead to defeat. "A penny saved is worth two earned," and no season of the year affords the farmer a better opportunity to reap the benefit of this great truth than the early portion of the month of October. In the Northern regions root crops must be gathered and marketed or securely stored; sorghum must be harvested and manufactured into syrup or sugar; corn must at least be cut up and placed into stooks; buildings must be erected, repaired and put in a good state of preservation; implements must be housed for a season of rest, and should be painted and oiled to preserve them from decay and rust; stock must have extra feed to prevent loss of flesh, etc., etc.

Agricultural Exhibitions are still to be held in many localities, and those who read the *Agriculturist*, and consequently raise the best crops and stock, and reap the largest ratio of profits, will not fail to be on hand to exhibit the evidences of their skill, and to obtain hints that will enable themselves to do still better another year. The farmer who never goes to the Fairs usually drives a miserable team, has "bad luck" with his crops and everything else; and "Hard Times" never abed him.

Barns—The suggestions given last month are still applicable, and should not be neglected.

Beans—Shell as soon as well dried, and clean thoroughly. The stalks are good fodder for both sheep and horses.

Beeves require increased care and feed. Pumpkins, immature corn, surplus cabbage leaves, will be acceptable to them, and prepare them for "finishing off."

Buildings—Erecting new, and repairing and painting old, preparatory for winter's storms and frosts, must be attended to promptly. Good shelter for stock pays a large per cent., in the saving of fodder. Food is the fuel which keeps up internal heat; the less exposure, the less the internal heat and consumption of fuel required.

Butter—Lay up a good supply, well made, thoroughly worked, and carefully packed. (See page 278 last month.) Keep up the supply of milk by feeding oil cake, cabbages or carrots to the cows, where pasturage is becoming short.

Cabbages must be taken care of before liable to injury by freezing and thawing. Freezing will not injure them materially, if so enveloped in earth or otherwise that they will remain frozen until wanted for use. They must have a very cool place to prevent decay, and they will not therefore keep well in cellars. Trenches, with a couple of rails laid on the bottom, are best. Place the heads of the cabbages on the rails, with roots up, then put a layer of straw against either side, cover with earth and pack smooth so as to shed rain as much as possible.

Cellars—Cleanse and ventilate as directed last month.

Carrot tops as well as roots are good for milch cows.

Cisterns—Cleanse and repair at once wherever needed.

Corn—The best ears may still be selected for seed, though for earliness the selection should have been attended to when the corn first began to ripen. Cut up, bind and stook for husking, if not ready to husk now.

Draining—Water should not be allowed to stand during winter on grain fields. Underdrain if possible, otherwise (unless the clay substratum can be bored or dug through) surface-drain with furrows or ditches well opened.

Farmers' Clubs—The evenings are lengthening and most farmers will soon have spare time, some of which may well be devoted to meetings for mutual benefit. Let each unit strive for the proud distinction of producing the best crops and stock in the world, or at least in his own neighborhood. Apportion experiments among the members and endeavor to earn for the club the credit of having originated something for the benefit of American Agriculture, as well as for themselves. Well directed and persevering effort often produces wonderful results. Let not the effort be wanting.

Forest leaves are excellent for absorbing liquid manure and for mulching. Gather them freely when available.

Grain—Thrashing, cleaning, storing and marketing must be attended to. Do the cleaning thoroughly. An extra winnowing may greatly increase the market value.

Hogs may be made to answer two purposes, manufacturing manure for the garden, and supplying pork for the table. Give them muck, soda, leaves, straw, etc., for the former, and good cooked food and clean water for the latter. It pays well to give frequent scrubbings to ensure cleanliness and thrifty growth.

Ice Houses rightly constructed and well filled are conducive to profit and comfort. (See remarks on page 297.)

Implements should be carefully secured against accident, rot and rust. Iron and steel will be kept from rust by smearing them with lard and resin melted together.

In-door Work should have the benefit of labor-saving implements—a sewing and a washing machine, wringer, churn, apple-parer, knife and scissors-sharpener, etc. Wives are too often over-tasked. Severe exertion should not be added to the incessant cares and steps of the housewife from early morning until late evening. If a man should be "merciful to his beast," how much more so should he be merciful to his wife! In far too many cases these hints are *needed*, we regret to say.

Manures are the touchstone to profitable farming, (except in very rich new soils) and every available source should be profited by to the fullest extent. Muck, forest leaves, green weeds, straw, etc.—in short, every kind of vegetable matter—composted with animal droppings, are the very best, as well as the most easily obtained. Lime, plaster, salt, guano, etc., are more or less valuable, according to the soil. Bones are always valuable.

Paint wherever preservation can be promoted. (See recipe for cheap paint for out-houses, fences, implements.)

Plow—Turn up an inch or so of subsoil on heavy soils, when the ground is dry, and let Jack Frost have a chance at it. In this manner his services are very valuable.

Potatoes are injured by sunlight, by extreme heat or cold, and by want of ventilation; hence in storing they must have a dark, cool, and well ventilated place, with sufficient protection to prevent the least freezing.

Poultry—See article on page 268, Sept. *Agriculturist*.

Pumpkins—Sound ones may be kept until late in winter if protected from frost, dampness, and heat. Or they may be pared, sliced in rings of half an inch in thickness, hung on a pole in the kitchen or any warm place, and dried. The seeds should be removed from those fed to milch cows, as they are supposed to lessen the flow of milk.

Root Crops for keeping require protection from frost, dampness and warmth (except sweet potatoes). Turnips may be the last gathered, before freezing weather.

Rye may still be sown. (See page 276, last month.)

Schools—See that school houses are in good order, and use all proper efforts to secure good teachers, and a full attendance. A good teacher is cheap at any price; a poor one is dear even if he work for nothing.

Sheep—Keep rams and ewes separate until five months previous to the time you wish lambs dropped. For early lambs, put rams with ewes middle of this month, but as a general thing the middle of March is rather too early for lambs. From first to middle of May is better. Both rams and ewes for breeding should have good pasture now.

Sorghum—Strip off leaves a few days before cutting up the stalks. Cut off two upper joints with seed, as soon as ripe, or before heavy frost, and cut stalks just above lower joint at the same time. Preserve from frost and manufacture into syrup or sugar as fast as possible.

Timber for rails, posts, etc., is better cut now than later.

Orchard and Nursery.

The great yield of most kinds of fruit this season will tend to increase activity in the orchard and nursery business. This will be counterbalanced in some degree by the alarms and demands of war. Still we may expect considerable activity in the fruit-tree trade. We hope to be able to chronicle the realization of these expectations, for there can be no good reason to doubt that fruits are promotive of the health and comfort, as well as the prosperity of our people. Good trees are cheap now.

The falling of the leaves is the signal for transplanting trees, and some do not wait for this, but strip them off by hand. Should frosts be too long delayed, this may be advisable, in order to give the newly-planted trees time to become established in the soil before Winter sets in. Those who contemplate planting an orchard, be it of few trees or many, can not be too well informed as to how it should be done. If anything pays for doing *well*, it is fruit-tree planting. On the manner in which the tree is set out, may depend not only the degree of its thrift and fruitfulness, but its very life. It may be well for those who are not acquainted with this subject, to engage the nurseryman to plant the trees himself, and warrant them two years, where this is practicable. Elsewhere in this number will be found some general directions.

Fall planting is generally advantageous on account of time, which is easier spared in the Fall than in Spring, while all the hardy fruits, including grapes, currants, blackberries, etc., are found to do quite as well planted in the Fall. The soil settles about the roots, and the trees are ready to begin growing as soon as Spring opens.

Gathering fruit is an important item in the orchard labors for October, and its good keeping will depend materially upon the degree of carefulness with which it is handled. It is well to use a good fruit-picker, at least in gathering choice, late-keeping varieties.

Insects—Give them no quarter. Exterminate every vestige of the pests. Look after borers, eggs, nests, etc.

Label every tree, or, what is better, make a map of the orchard and put the name of each tree on the map. It is well to do both. Mice should find no harbor in grass or weeds around the trunks of fruit trees.

Manuring an orchard properly, requires a good deal of discretion. Experiment has proved that the soil for peach trees may be too rich; while on the other hand, pear-trees are gross feeders, and will mature abundantly. A compost of animal droppings, rotten leaves, sods, ashes, night-soil, etc., make a good pear-tree fertilizer, while chip manure and finely pulverized barn-yard manure in moderate quantities are excellent for apple trees. Lime is also almost universally beneficial to apple trees. Spread manures this month, and work them in in Spring.

Seeds and Pits—Plant at once, or store them in moderately dry sand until ready to plant in early Spring.

Stake up all trees liable to injury by winds. Be sure to heed directions for staking on p. 209, July *Agriculturist*.

Taking up nursery trees should be carefully done, to avoid injury to the roots, and those broken should be cut off smoothly and shanling from the under side outward. Immediately immerse in mud the roots of those to be sent to a distance, or for other reasons not to be immediately re-set. Reduce the tops of such as have broken or reduced roots. Damp moss or litter should be well packed and bound on around the roots of those to be sent to a distance.

Under-draining on heavy soils is always advantageous, and where needed no further delay should be suffered.

Kitchen and Fruit Garden.

The season for cessation of labors in the kitchen and fruit garden is near at hand, and what remains to be done should not be put off a single day longer than is absolutely necessary. Besides properly storing such of present crops as can not be used or marketed before frosts, there is much that may be done to enhance next year's profits, the most important of which is annihilating all weeds and turning up new subsoil (on all, and especially on clayey soils) to be amended by the action of frost and air.

Apples for keeping must be most carefully handled, even if very firm. Russets will bear gathering first, and other late-keeping varieties in succession, bearing in mind the liability of the large kinds about ripe, to danger by Fall storms and winds. Common kinds may be stored in a cool, dry room, though it is better to put them carefully into dry barrels. Choice specimens may be wrapped singly in clean paper and packed in dry chaff or bran.

Artichokes need Winter protection of earth or litter, before hard freezing, to be removed early in Spring.

Asparagus is better, and time is gained, if sown or the roots planted out early this Fall. The deeper and richer the bed the better. Set plants one foot apart each way, with the crown or branches below the surface.

Beans—Those unripe at the approach of severe frost should be shelled and dried by the sun or in an oven. Shell Limas and store in cool, dry place. House the poles.

Beets—Cut off tops and dry a little before housing.

Blackberries—New plots of this excellent fruit may be set this month—as soon as the leaves fall from the plants. Enrich soil with a compost of leaves, turf and well rotted manure. Set the large kinds, like the New-Rochelle, 4 feet distant in rows 8 feet apart. Protect the young canes the first year with straw or manure, if liable to much freezing and thawing. Plants may be grown from seed, but the variety will be uncertain.

Cabbages—The hardy kinds may be wintered by simply re-setting close together and covering with a few inches of loose litter. Tenderer kinds should be set in trenches, head down, on a couple of rails, and the roots well covered with straw and earth. Sow seed in cold frames for early Spring plants.

Carrots—See directions for beets. See also "How to Harvest Carrots," page 300. Pies are made by grating raw or stewed carrots, passing the pulp through a sieve, and then proceeding the same as with pumpkin sauce.

Cauliflowers may still be sown in cold frames.

Celery—Remove decaying leaves, and earth up with dry soil before danger from frost. Keep dirt from between the leaves by holding them together. Celery must be kept dry and cool, and protected from frost.

Cold frames may still be made in time for profitable use.

Currants and Gooseberries—Plant out last of month.

Fruit Trees—Transplant last of this month, and take time to do it well.

Grapes—Gainer as fast as ripe, remove all defective berries from those bunches you wish to keep, and pack in a dry, cool place, between layers of cotton batting. For wine-making see page 277, September *Agriculturist*. Set new roots last of this month.

Lettuce—Sow in cold frames. Remove late sown to cold frames before severe weather, or protect with clean litter that will also hold snow.

Onions—Sow in very rich, light soil, in drills a foot apart. Give slight protection of litter. These will start very early in Spring.

Parsneps wanted for Winter use should be dug, topped and buried in sand in the cellar. Leave others where they grew, until Spring. They are improved by freezing.

Pickles—Pack unripe tomatoes, melons, peppers, etc., in salt for pickling.

Rhubarb—Plant new roots and seed, the last of this month.

Salsify or Vegetable Oyster—Treat exactly as directed for parsneps.

Spinach—Thin out young plants and give a slight protection before heavy frosts.

Strawberry Beds—Make new ones immediately and cover before hard freezing. Sprinkle new and old beds with wood ashes, and cover lightly with tan bark, forest leaves or straw.

Sweet Potatoes—Pack in very dry sand and keep in a warm place.

Tomatoes—Fruiting may be prolonged by keeping off frosts with light protection—such as thin cloths, etc.

Trenching—Do this now wherever needed. Few are the gardens in which it will not pay. Deepening—not over-turning—the soil, should be aimed at.

Turnips—Late varieties may be permitted to remain and grow until another month.

Flower Garden and Lawn.

As Winter approaches, the flowering shrubs and plants in bloom become reduced in variety, so that in October dahlias, gladioluses, and chrysanthemums occupy nearly the entire field of hardy plants; yet, with proper care and taste in selecting varieties, removing all decaying leaves and other unsightly objects, and arranging for effect, these may be made quite efficient in gratifying the love of the beautiful. Attending to these, cleaning up flower borders, sowing and transplanting perennials, potting bedded plants, setting bulbs, saving seeds of late bloomers, protecting or removing tender varieties to flower pits, greenhouse, cellar, or window, planting shrubs, trenching and seeding, or turfing lawn, and transplanting ornamental trees, constitute the main labors of October, in the flower garden and lawn department.

Bedded Plants—Take up and pot petunias, verbenas, fuchsias, geraniums, salvias, etc., for winter blooming. Make cuttings, and place in boxes or pots of light sandy soil at once.

Bulbs may be planted at any time from September to December, but are better when put in early. Plant in any good garden soil, covering from two to four inches. (See article on page 273, Sept. *Agriculturist*.)

Chrysanthemums are now in the hight of bloom, and their rich colors and varied and delicate shadings render them very attractive. Keep carefully staked to prevent injury by Autumn winds, and promptly remove all decaying leaves, etc. Mark choice blooms to divide and re-set roots in Spring.

Dahlias and Gladioluses—Treat as directed for Chrysanthemums, except to remove to a cellar or other dry place where they will be protected from freezing.

Frames and Pits—Prepare for the early reception of plants. (See illustrated article on page 273, Sept. *Agriculturist*.)

Perennials—Hollyhocks, wall-flowers, etc., do well if sown first of this month.

Lawn—Trench or subsoil and manure where needed. In turfing, beat sods well down, and fill all crevices with fine soil or sand. Sow early, and roll immediately after sowing, and again just before Winter. Perennial ryegrass is esteemed for lawns, but Kentucky blue-grass suits us best.

Pinks, Carnations, etc.—Pot rooted layers and young plants for removal to pit or green-house before frost.

Shrubs—Plant hardy, early-blooming varieties.

Green and Hot-Houses.

Directions of last month apply in the main to this also. As the exact time of first severe frosts can not be foretold, and *may* occur much earlier than usual, there should be no delay in securing from injury all tender plants which it is desirable to preserve. Guard against sudden changes in temperature, keep the houses well ventilated, and induce a degree of humidity within, by judicious sprinklings or syringings of water. Place the tender plants in the safest locations, with reference to uniform warmth of temperature.

Annuals—Sow a few quick-growing sorts to come into bloom in mid-winter.

Insects should be promptly exterminated upon first appearance.

Apiary in October.

Prepared by M. Quinby—by request.

The bees will add nothing to their stores the present season, except in localities where but few are kept, and the Golden Rod and Wild Aster abound. The brood is mostly matured, and now is the time to decide what to do with each stock. Good stocks contain a strong colony, and plenty of honey, say 25 lbs. When doubtful as to their condition, weigh them. Some judgment is needed to decide about the number of bees. If the hive is very full of honey, the bees will be crowded to the bottom, and will appear to be more numerous than they really are. When combs are full of foul brood, the bees are crowded to the bottom in the same way. But when the combs are ordinarily stored, the bees will be near the bottom, and extend through all of them. Such usually winter best. When stores of honey are a little short, the bees will be further up among the combs, and a large colony may appear quite small. These things should be thought of, that no mistakes be made. If deficient stocks are to be kept, select first such as have bees and combs enough, and supply honey to others. When bees are wasting, there are generally enough of the condemned ones that must be sacrificed, to supply them.

There may be some old stocks found that are yet queenless, with abundant stores. Introduce a good colony with a queen now, if free from worms, and convert it at once into a stock for winter. It does not always make the best, but it is the best use to which such can be applied. If honey from the south, or that from hives containing foul brood is fed, it should be cleansed by scalding, adding a little water to prevent burning. All the feeding should be done quickly, and with especial care to prevent robbing.

The honey market is most active this month and next. Take off all dripping honey from the outside of the boxes with a wet cloth; paste heavy paper, or thin muslin over the bottom holes to cut out insects and dirt. Put up large boxes, that will hold what can be easily handled. Secure it from sliding about, and handle with extreme care. Full prices can not be obtained for broken combs.

Exhibition Tables at the Office of the American Agriculturist.

The following articles have been placed on our tables since the report for last month:

FRUITS.

The largest and finest collection of Apples and Pears by any exhibitor has been shown by Wm. S. Carpenter, of Rye, N. Y. It consists of over 90 varieties, including the choicest of named sorts. Size, color and specimens have been contributed by others, as follows:

Apples.—Gravenstein, Early Strawberry, Garretson's Early, Hawthornden, Melon, Summer Pearmain, Porter, Twenty Ounce, Rhode Island Greening, Sweeting, Golden Sweet, from Parsons & Co., of Flushing, L. I.... Red Astrachan, Summer Queen, Golden Russet, Pine, from Dr. Ward, of Newark, N. J.....Alexander, Nonsuch, from C. P. Russ, of Staten Island....Gravenstein, from T. Whitbeck, of Yaphank, L. I.... Suffolk Beauty, Sweeting, from Edward L. Brown, of Deer-park, L. I.....Primate, from A. M. Halsted, of Rye, N. Y..... Variety for name, from Theo. Van Perg, of Rahway, N. J..... Strawberry, from B. C. Wyckoff, of Bergen, N. J.....Variety for name, from Jas. L. Lockwood, of Stamford, Conn.... Northern Spy, Baldwin, from Matthew Armstrong, of South Bergen, N. J.....Varieties for name, from Jas. Brown, of Morrisania, N. Y.....Alexander the Great, Summer Queen, from Geo. Ludington, of Ludingtonville, N. Y.....Alexander, (one of four grown on tree 8 feet 7 inches high) from C. H. Lillienthal, of Yonkers, N. Y.....Specimens, from Phillip Frank, 530 Broome street, N. Y.....Porter, Primate, 2 varieties for name, and others from E. Williams, of West Bloomfield, N. J.....Sweet Bough, Branch of Siberian Crab, from J. R. Whiting, of Spuyten Duyvil, N. Y.....Bunch of 12 apples, from G. M. Diller, of Port Richmond, Staten Island.....Nonpareil, from E. S. Y. Wright, of Forest Home, N. J.....Sour Bough, from J. C. Hart, of Shrub Oak, N. Y.....Cherry Crab, from Wm. Churchill, of Smithtown, L. I.....Two branches Crab, from A. J. Hall, N. Y.....Varieties for name, from A. J. Caywood, of Modena, N. Y.....Varieties for name, from Wm. Churchill, of Smithtown, L. I.....Variety for name, from Mr. Paterson, of Perth Amboy, N. J.

Pears.—Flemish Beauty, St. Ghislain, Knight's Seedling, Summer Franc Real, Kirkland, Bezi de la Motte, Julienne, Beurre Blanc, Frederick of Wurtemberg, Andrews, Paradise d'Automne, Summer Bergamot, Beurre Chirgean, Brandywine, Moulle Bouche, Golden Beurre, Stevens' Genesee, Beurre Rance, Howell, Henkel, from Parsons & Co., Flushing, L. I.....Sterling, Doyenne Boussock, Bartlett, from Dr. Ward, Newark, N. J.....Belle de Bruxelles, from Theo. Van Perg, of Rahway, N. J.....Church, Partomen, Flemish Beauty, and a variety for name, from D. F. Welch, of Bergen, N. J.... Beurre d'Amaulis, from Mr. Eakin, of Staten Island.....Bartlett, Beurre Chirgean, Seckel, Monsieur Johns, varieties for name, from Mr. Paterson, of Perth Amboy, N. J.....Bartlett, Flemish Beauty, Urbaniste, Andrews, Belle Lucrative, Lawrence, Seckel, Louise Bonne de Jersey, Glout Morceau, Vicar of Winkfield, Maria Louise, from Matthew Armstrong, of South Bergen, N. J.. 5 Bartletts (magnificent, weighing 2 lbs, 4 ozs.), from R. Leavitt, of Flushing, L. I.....Variety for name, from J. L. Worth, of Bayswood, L. I.....Beurre d'Amaulis, from C. Rogers, Enfield, N. J.....Variety for name, from R. J. Dodge, Montclair, N. J.....Dearborn Seedling, Bartlett, from L. C. Hatch, of Scotch Plains, N. J.....Variety for name, from J. Holt, of Havcrstraw, N. Y.....Beurre d'Amaulis, (branch bearing 61 *fine* pears—imported dwarf grafted on standard), Louise Bonne de Jersey, Stevens' Genesee, Flemish Beauty, Church, Belle Lucrative, Bartlett, Water Melon, Seckel, Huntington, Bleeker's Meadow, Pig Pen, Duchess d'Angouleme, Vicar of Winkfield, Beurre Bosc, a variety for name, from A. M. Halsted, of Rye, N. Y. Doyenne Boussock, Sens Pan, variety for name, from L. A. Brush, Long Island.... Washington, from A. B. Fuller, of Brooklyn, L. I.....Varieties for name, from R. Lewis, of Brooklyn, L. I.....Beurre Chirgean, Louise Bonne de Jersey, from Mrs. C. M. Kirtland, N. J.....Dearborn Seedling, Flemish Beauty, Tyson, Bartlett, from Wm. Chorlton, of Staten Island.....Seedling, from E. E. Clarke, of New Haven, Conn.....Variety for name, from Mr. Livingston.....Beurre d'Amaulis, Flemish Beauty, Bartlett, variety for name, from Jos. L. Noble, of Brooklyn, L. I.... Variety for name, from B. Conover, New York.....Stevens' Genesee, Bartlett, Belle Lucrative, New Frederick of Wurtemberg, Andrews, Beurre d'Anjou, varieties for name, from L. Mason, of Orange, N. J.....Andrews, Flemish Beauty, Bartlett, from Mr. Child. New Market, N. J.....Bartlett, Flemish Beauty, Doyenne Boussock, Beurre Chirgean, Surpasse Maria, Belle de Jerseys, Beurre Foughiers, variety for name, from J. K. Gibson, Keyport, N. J.....Specimens, from Thos. B. Stimson.....Varieties for name, from M. M. Hurd, of Brooklyn, L. I.....Bartlett, Seckel, variety for name, from Jacques Van Brunt, of New Utrecht, L. I.....Seckel, from Ed. Humbert, Brooklyn, L. I.....Doyenne Boussock, variety for name, from T. B. Stilman, of Flatnicki, N. J.....Beurre d'Angouleme, New Frederick of Wurtemberg, Flemish Beauty, from C. Reeve, of Southold, L. I.....Virgalieu, variety for name, from Mr. Lawrence, of Hyde Park, N. Y.....Beurre d'Amaulis, from Daniel Coe, New Paltz Landing, N. Y.....Variety for name, from J. Hague, of Bloomfield, N. J.....Bartlett, variety for name, from R. Williams, of West Bloomfield, N. J.....Beurre d'Amaulis, from H. C. Ward, of Newark, N. J.....Bartlett, Seckel, from B. T. Sealey, of South Yonkers, N. Y.....Variety for name, from T. B. Reed, of Flushing, N. J.....Bartlett, from J. R. Whiting, of Spuyten Duyvil, N. Y.....Doyenne Boussock (very fine), from J. R. Rapelye, of Astoria, L. I.....Bartlett, from J. H. Stuart, of Stapleton, N. Y.....New Frederick of Wurtemberg, Doyenne Boussock, Flemish Beauty, Bartlett, Beurre d'Amaulis, varieties for name, from John C. Hart, of Peekskill, N. Y.....Collection of pears for name, from H. L. Terry, of Brooklyn, L. I.....Bartlett, and others, from Thos. Andrews, of West End, N. J.....Variety for name, from Mr. Wyckoff, of Bergen, N. J.....Varieties for name, from Rev. J. Weaver, of Fordham, N. Y. Varieties for name, from Dr. R. Morrison, Spring Valley, N. Y.....Hacsmas, variety for name, from P. L. Bogert, Brooklyn, L. I. .....Variety for name, from C. A. Whitney.....Beurre d'Amaulis, from J. H. Ruptst, of Hudson City, N. J.....Bartlett, from Mr. Ayres, of Astoria, L. I.

Grapes.—De Candolle, Delaware, from Parsons & Co., of Flushing, L. I.....Rebecca, Hamburg, Wilmot's Hamburg, Bowker (white), from Matthew Armstrong, of South Bergen, N. J.....Wild Grapes (large), from George O. Street, Mt. Vernon, N. Y.....Hartford Prolific, from Mr. Child, of New-market, N. J.....Variety for name, from Geo. W. Prince, of Brooklyn, L. I.....Delaware, Diana, (open air, a little earlier than Delaware) from E. Hergt, of Rye, N. Y.....Black Hamburg, Sweet Water, from C. Mandewirth, of Fishkill, N. Y.

Plums.—Green and Yellow Gage, ten varieties for name, from E. Williams, of West Bloomfield, N. J.....Variety for name, from J. M. Stevens, of Long Slip, N. Y.....Green Gage, Coe's Golden Drop, Black Plum, from L. Mason, of Orange, N. J.....Gage, from Jas. Quick, of Brooklyn, L. I.....Sine varieties of Seedlings, from Mrs. Thos. Young, of Long Slip, L. I. .....Bolmar's Washington, variety for name, from J. H. Demarest, of Washington Heights, N. Y.....Bolmar's Washington, from Samuel Cooper, of Tompkinsville, Staten Island.....Gage, from E. S. Lamoreaux, Basking Ridge, N. J.....Branch Green Gage (3 plums, 2 inches, 2 inches, grown on tree 8 years), from Clarence Sidell, of Classon Avenue, Brooklyn, L. I.....Four branches (amazingly full—*fine fruit*), from Dr. S. I. Chase, of Lockport, N. Y.....Lawrence, Variety for name (very fine), from Mrs. Lathrop, Saugerties, N. Y.

Peaches.—Seedling for name (named Hinchman's Seedling) weight 7½ ozs. from tree 12 or 14 yrs. old, grown in Brooklyn, L. I., from J. J. Hinchman, 26 Yeager st., New York.....Van peach, from Sulphin Lyon, of Washington Market, New York. .....Carman Peach, from Wm. S. Carpenter, of Rye, N. Y. Seedlings, from Henry Smith, St. James, L. I.

OTHER FRUITS.—*Nectarines.*—Red Roman (very fine) from Frederick Seitz, of Easton, Penn.....Specimens (fine—grown in the city), from Mrs. Lathrop, of New York.....*Prunes* from Capt. Reimer, of Orange, N. J.....*Strawberries.*—Jenny Lind (second crop), from A. S. Fuller, of Brooklyn, L. I.....*Blackberries.*—Dorchester (*Lawton*—large, or else new-fine), from John Cole, of Tompkinsville, Staten Island.....*Tomatoes.*—Red Smooth, Red and Yellow Pinm, Currant, Fejee Island, Plum Tree, and new variety (half yellow and half red) from W. F. Heina, of Woodstock, N. Y.....Cuban, Fejee, Tree, and a new variety, (half yellow and half red) from Geo. M. Suffer, of Port Richmond, Staten Island.....Specimens (large and fine), from W. H. Storrs, of Hudson City, N. J.....Mammoth, from John Cole, of Tompkinsville, Staten Island.....Mammoth, from J. Wilson, New Durham, N. J.....Mammoth, from J. H. Demarest, of Washington Heights, N. Y.....Trinity from Walter Johns, of Passaic, N. J.....Italian, and bunch weighing 12 pounds, from Mr. Fitzgerald, gardener to Gen. Henry Stornes.....Tree (in pot), from Frederick Seitz, of Easton, Penn.....Specimens (singular growth), from Archibald Alexander Stevenson, of Altonwood, Westchester Co., N. Y.....West India, from L. A. Berte, of Tremont, N. Y..

Large specimens, from John Davidson, Washington Heights, N. Y.:—Yellow, Branch of Perfected, (very prolific and fine) from A. C. Chamberlain, of Novelty Gardens, Brooklyn, L. I.,—Large specimens, from B. F. Carpenter, of Newbrugh, N. Y.;—Mammoth, from A. Peyrot, of Tremont, N. Y.;—Italian, from A. M. Agens, of Orange, N. J.

VEGETABLES.

Three Garnet Chili Potatoes from single eye, (product of 12 potatoes weighed 38 lbs. with slight manuring) from J. Wilson, of New Durham, N. J.;—Japan and Chinese Beans, Hindostan Wheat, Chinese Egg Plant, Zea Caragua, or South American Corn (great growth), from Wm. F. Heins, of Woodstock, N. Y.;—Hops, Fancy Gourds, from Mr. Deserve, of Bergen Hill, N. J.;—Java Coffee, from B. McFarland, of Holbrook, L. I.;—Blood Beet (very large) from Benj. F. Seaver, of Orange, N. J.;—Chinese Egg Plant (in pot) from Frederick Seitz, of Easton, Penn.;—Corn, (curious growth) from Jas. Salter, Delmonico Castle, Brooklyn, L. I.;—La Guayra (raw) Coffee, from Mr. Willett, of Caracas, Venezuela, South America;—Vegetable Marrow Squash, Fancy Gourds, Oak Apple, from Charles Mandewirth, of Fishkill, N. Y.;—Hops, Fancy Gourds, from Mr. G. Usher, of Port Richmond, Staten Island, N. Y.;—Contraband Corn, from J. A. Brewer, of Westfield, N. J.;—Red Pepper (grown like Tomato) from J. A. Warman, of Westfield, N. J.;—Italian Chestnut, from Wm. Churchill, of Smithtown, L. I.;—Union Cucumber, from A. W. M. Hume, of Manhattanville, N. Y.;—Mammoth Twin Nutmeg Musk-melon (two grown together—perfect *Union*), Spanish Melon, Crooked Neck Squash, from Jas Van Dyke, of Flatbush, N. Y.;—Turban Squash, from Fritz Meyer, of 539 Third Avenue, New York.;—Fancy Balloon Gourds, from Thos F. Stewart, of Flushing, L. I.

FLOWERS.

Fine Double Balsams, Beautiful Pansies and Asters, and a splendid Double Zinnia, from Rev. J Weaver, Fordham, N. Y.;—Bloom of Cotton Plant, from F. Deserve, of Melrose, N. Y.;—Dahlias, Lilies, Double Zinnias, Roses, Gladioluses, Cut-flowers (very fine), from C. S Pell, of N. Y. Orphan Asylum.;—Asters, Dahlias, Lilies, Gladioluses, Zinnias, etc., from O. Judd, of Flushing, L. I.;—Double and single Sunflowers (extraordinary), from Henry C. Eno, of East Brooklyn, L. I.;—Sunflower (3½ inches in diameter), from Thos F. Stewart, of Flushing, L. I.;—Clethra Alnifolia, (wild flower) from John Jones, Hoboken, N. J.;—Wright's Datura, from T. W. Martin, of Williamsburgh, L. I.;—Dahlias, from Wm. Crowell, of Thompson, L. I.;—Dahlias, from Wm. E. Meserve, of Bergen, N. J.;—Asters, from H. C. Ward, of Newark, N. J.;—Amaranthus tricolor, Euphorbia variegata, Obelisceria Fulcherima, from an Amateur.

MISCELLANEOUS.

Branch of Tree with Oyster-shells attached (curious), from Wm. Stickler, of Newport, News, Va.;—Case of Honey (Quinby's Hives), from H. V. Crittenden, Bronxville, N. Y.;—Live Glow Worm.;—Balsam Apple, from John Mnerdten, of N. Y.

Fruit Growers' Meetings.

Large and Interesting meetings of Fruit Growers are now held at the office of the *American Agriculturist*, at 2 o'clock P. M., on Thursday of each week. Merchants doing business in the city, who have country residences, fruit growers from the neighboring localities, and even from distant points, farmers and others, come together for an hour or two, to test and discuss specimens of fruit, give names to unnamed fruits sent, talk over best kinds, and modes of growing—a pleasant and instructive meeting is the result. Our Tables are constantly loaded with from 250 to 300 plates of different fruits in their season. Flowers, vegetables, all sorts of soil products, and implements which are interesting or instructive, are invited on Exhibition at all times, and the public are invited to drop in on any day and at any hour whenever convenient. We have not room to report the doings at the Weekly Meetings, though some interesting points are brought out which it will be useful to publish hereafter. Separate items will be found in "Our Basket," and elsewhere, from time to time, as circumstances shall seem to require.

Save Fruit for the Soldiers.

An intelligent gentleman of this city, who knows by experience something of camp life, says, tell all the readers of the *American Agriculturist* that nothing is more acceptable to soldiers while confined to their army rations, than dried apples, and other fruits, which are easily carried in compressed bulk, and can be soaked and stewed with only the camp conveniences. There is an abundance of fruit, and, in addition to list, bandages, socks, etc., let every community prepare a lot of well peeled and well dried apples, peaches, etc., to forward as opportunity offers, to some favorite regiment or company, or to a central depot which we hope to have established in this city for this special purpose. Get the fruit ready, and a way will be opened for its use where it will be most acceptable. If no other way opens send it to the *Agriculturist* office, and we will forward it to any point desired.—After writing thus much, the gentleman referred to, added: "Yes, tell them to send the dried fruit here, if they have no other way to forward it, and my workmen and workwomen will repack it. my carts will do all the moving in the city, and I will bear all expenses of getting it from here to the soldiers' camps." He requested us to withhold his name. (The first citters are C. H. L.) Let these donations be plentiful.

American Pomological Society.

The Ninth Biennial Meeting closes at Boston, just as we go to press, and we have only room to say that the gathering of fruit-lovers was large, the discussions interesting, and the show of fruit, especially of pears, the largest ever brought together in the country. This was to be expected from the present great fruit year. Among the individual collections were: some 300 varieties by Prest's. M. P. Wilder; nearly 300 by W. Read, of New-Jersey; 250 by Ellwanger & Barry, who also exhibited 250 kinds of apples, and 75 varieties of plums; 250 varieties of apples by T. T. Lyon of Mich., many of them very large and of superior excellence. Other large collections were shown by Hovey & Co., Hooker & Co., of Roehester, and Wm. S. Carpenter, of N. Y.—Hon. M. P. Wilder, was re-elected President, and Jas. Vick, Sec. An address by the President, and remarks by Col. B. P. Johnson, giving an account of his visit to the London Exhibition, were listened to with interest.

Agricultural Exhibitions, Oct., 1862.

A large number of Fairs are in progress, as we go to press, and apparently with a fair degree of success, notwithstanding the war excitement. Below is a list of Fairs to be held in October, so far as we have been able to ascertain the particulars.

STATE FAIRS.

Name.	*Where held.*	*Date.*
Illinois	Peoria	Sept. 29—Oct. 4
New-York	Rochester	" 30 " 3

Containing a great variety of Items, including many good Hints and Suggestions which we give in small type and condensed form for want of space elsewhere.

THE READER'S ATTENTION, is invited to the business notices in this paper. Sundry General Premiums are offered on pages 313-14, and 320, which are worth looking after. The offer of the remaining numbers of this year *free* will be a special stimulus to new subscribers, and assist in making up premium clubs.

WAR MAPS.—All who wish a large, complete map of Virginia and the adjacent parts of Maryland and Pennsylvania, the present seat of the war in the East, will do well to avail themselves of the offers on page 320. Every person sending one or more new subscriptions, with his own, can have a map for each. The *Agriculturist* for November 1861 contained very complete maps of Kentucky, and Missouri, and a considerable portion of Tennessee. That number most of our readers have now. Those who have not can receive a post-paid copy for 10 cents. The map of the Southern States offered on page 320 will be very useful. The map of the United States is also a really fine one.

Those who have reported the Crops through the Summer, at no little trouble, and often at some considerable expense, deserve the highest thanks of all our readers, and of the country; they have ours most assuredly. These reports give more reliable information in regard to the crops of the country, than was ever before gathered at this early date in the season. —*One Request more.* In the reports for Sept. 10, we fear some did not note the change in the headings of columns **D—G—M—O,** where the number of *bushels per acre* was asked for. We shall be glad to hear at once on this topic. It will be interesting to know what is the average number of *bushels* per acre in different parts of the country. The duplicate blanks on hand might be filled up under these columns, where any mistake was made.

The Pumpkin and Gourd Exhibition, comes off next month. (See announcement elsewhere.) All who have large, extraordinary, or otherwise interesting specimens of Pumpkins, Squashes, Gourds, etc., are invited to exhibit them; but please give us early notice of what is coming, that we may provide room. Of course no one will leave us to pay expenses for the carriage of specimens—as the exhibition is free to all. A competent disinterested committee will award the premiums, and decide all questions of prizes according to the terms of the offer.

When to Sow Spring Wheat.—A Farmer in Iowa, says in connection with his crop reports that his experience tells him that if the importance of early sowing of Spring wheat could be impressed upon the public generally, the increase in the crop would be worth millions of dollars. The very earliest spring we take up is from N. Y. State, and on the same point says: "Early sown Spring wheat will hardly pay for harvesting, while late sown has mostly escaped, and is much better—some going over 25 bushels per acre."

Caution—Wheat.—Several subscribers at the West inform us that the "Mammoth Wheat," and the "Hallett's" Pedigree Wheat," distributed from the *American Agriculturist* office, is being extensively advertised for sale at high prices. We hardly see how this can be, as we only sent out small parcels to individuals, and Mr. Hallett informed us the present year that he had not had orders from America to any amount. There may be a little for sale, by responsible parties, but it will be well to look out for speculators. One of the parties advertising is not on our books, and could not have had the seed from our office.

Free Homesteads in Iowa.—We learn from Iowa papers ,that there are about 40,000 acres of Government lands in Humboldt County, 50,000 acres in the vicinity of Fort Dodge, and 4,000,000 acres near Sioux City, "as choice as any in the State." Those near Fort Dodge are "railroad" lands, being adjacent to the Dubuque and Sioux City railroad. All Government lands are open for free settlers under the Homestead Act.

What of the Steam Plow ?—On the 26th of June, the owners of the several steam-plows in England, brought out their implements in full force at Farningham, 24 miles southeast of London, and devoted three days to extended field trials under the auspices of the Royal Agricultural Society, then holding its great Show at Battersea Park, London. We spent some time at Farningham, carefully watching the operations on the different plows, with reference to the feasibility of their introduction into this country. The conclusion we came to was, that while these plows are adapted to some of the heavier lands of England, where human labor is cheap, but horse labor dear, they have too much rigging, and require too many attendants to allow of their general introduction into the Eastern and Middle States. A skillful man, with $6000 to $12000 capital, would most probably find it profitable to procure one or two of them, and make a business of plowing for others on the Western prairies. Some gentlemen of our acquaintance are sanguine that there is in this country a new steam plow, nearly finished, which will prove a complete success. It is to be thoroughly tested before being brought before the public.

Screw Stump-Blaster.—Not recollecting any other, we use this name for a simple but ingenious implement we saw in Dr. Rau's collection at Hohenheim Agr. College, Germany. In removing large stumps, and splitting tough, knotty logs, it would be more frequently desirable to use gunpowder, but for the difficulty of putting a firm tamping over the powder, and the trouble of using fuse or a priming rod. The apparatus referred to is simply an iron screw, with a deep thread, and a small hole lengthwise through its center. The same hole being bored in the wood, the powder is placed in the bottom and the screw, which is larger than the hole, is worked down upon it by means of a loose lever in its outer end. The center aperture is then filled with priming powder for firing. The thread holds even strongly rotten wood or brick tamping, and the same screw may be used for any number of logs or stumps. Any blacksmith might get up such a screw. There was one either at the International Exhibition, or at the Batterses Park Show, in London, but we believe this implement is not patented in this country.

Drains Stopped by Roots.—A Shaker Friend has left for exhibition at the office of the *American Agriculturist*, a remarkable specimen of root growth which we value at little damage. It is a portion of the roots of a maple tree, which stood in a meadow, near a stone drain. It is a compact mass of roots about two feet long and a foot wide, which had matted themselves about the stones of the drain and effectually prevented the passage of water, thus causing an overflow and greatly injuring several acres of grass. This occurrence suggests the necessity of removing trees from the line of drains, or in some way preventing their roots from thus causing obstruction. An important statement often insisted upon in these columns is also exemplified; viz., that, other conditions being favorable, an open porous soil is most conducive to growth. The roots speedily found their way among the interstices of the drains, and fattening upon the deposit from the water, developed into surprising growth. A tree with plenty of such fibrous roots, would have a corresponding vigor of trunk and branch.

Sale of Devons.—On September 10th, R. Lindsley Esq., of Meriden, Conn., held an auction sale of pure Devon cattle. E. H. Hyde, of Stafford, Conn., bought "Majestic" (imported), "Nelly Bly," "Nelly Bly 2d," and "Fanny 3d," (two years old); also yearling bull "Prince John 2nd." Hon. John Wentworth, of Chicago, bought "Fairy 2d" and calf, also two bull calves, one out of "Nelly Bly 2d," the other out of "Empress Eugene 2d." Levi Yale, of Meriden, Conn., purchased "Nelly Bly 5th." Mr. Buffum, of Newport, R. I., purchased a bull calf out of "Chance." Mr. L., intended to sell all his Devon stock, but so few buyers were present, further sales were postponed one month.

Curculios in Apples.—At a recent meeting of fruit growers, held at the *American Agriculturist* Rooms, Dr. Trimble, of Newark, N. J., exhibited curculios obtained by putting wormy apples which fell in June, into barrels of earth, and covering with millinet. The curculios hatched out in great numbers, and were retained by the covering. We have at our office a bottle of them alive and active; we feed them with pieces of pears which they appear to enjoy. This proves conclusively that when plums are scarce, as they were where these apples grew, the curculio will take to other fruit. Dr. T., who has made this insect a study for years, says they do not spend the winter in the ground, but in the rough bark of trees, or other hiding places.

Scalding Peaches to Peel Them.—W. Hunt, N. Y. City, informs the *Agriculturist*, that he has tried scalding peaches the same as tomatoes, to loosen the skin, and finds it an admirable plan for peaches that are *fully ripe*. Put them in a pan, pour boiling water over, and let them stand a minute, but not long enough to cook beyond skin deep. The skins will then cleave off readily without waste, as we have proved by trial.

Distance Apart of Apple Trees.—"Inquirer." You will find a discussion of this subject in the Nursery Catalogue of Messrs. Stephen Hoyt & Sons, of New Canaan, Conn., which is furnished free to all applicants, we suppose. They advise 18 feet apart when the orchard is the chief thing; and 36 to 40 feet, if crops be the principal object, and fruit a secondary one. Their reasons for this advice are plausible.

Standards and Dwarfs—The Difference.—D. Millikin, Butler Co., O. Standard trees are those which have undergone no change of *species*. They may be grafted or budded at pleasure, but retain the name of standard, though frequently dwarfed a little in habit. Proper dwarfs are those in which the species is changed by grafting or budding one sort upon a weaker or smaller growing stock of another species, as for example, the pear upon quince, apple upon paradise stock, etc. If you bud or graft the shag-bark walnut (called hickory nut,) upon the pig nut hickory, you neither make it a dwarf nor bring it early into bearing, as one variety is about as robust as the other.

Trimming Tomatoes.—A. A. Horton, of Fon du Lac Co., Wis., writes to the *Agriculturist* that, "trimming tomatoes not only improves their quality but hastens their maturity several days." This deponds upon the amount of cutting in. Without a fair supply of leaves no plant can mature its fruit well. The outer branches of tomatoes, and of vines generally, on which the green fruit can not mature before frost, may well be clipped off.

Striking Grape Cuttings.—E. W., of Hammonton, N. J., set 10 grape cuttings last season and lost but 6 of them. He follows out the direction of a German gardener, pruning the vines in Winter, and on the 10th of March he put the cuttings in a pail of mud and water for a week. They were then set in prepared trenches and started vigorously upon the approach of warm weather. The cuttings were put one half their length in the mud, and only a single eye was left above the surface.

Grapes from Seed.—N. S. Thornton, Randolph Co., Ind. Grapes from seed vary quite as much as apples. It is seldom that more than one out of a hundred seedlings is worth raising. The business is therefore best left to amateurs and professional growers, buying of them roots of such kinds as are wanted. A good kind obtained, can be increased by cuttings and layers.

The Camellia as a House Plant.—"Sophy." Your ill luck is not the first; the buds are very apt to wither and drop. To help you, here is a little advice. First, see to it that your soil is made up of turfy, spongy, fibrous soil from the woods. Have the pots well drained. Keep the plants in a cool room at first, say from 40° to 50°. When the buds are well developed, keep the soil wet; the saucers should never become entirely dry. When the buds begin to expand, bring the pots into the parlor or living-room, and give more heat. Sprinkle the foliage and keep the ground moist. In February and March, you may expect a fine show of blooms. Diminish the water as soon as the flowers begin to fade.

Removing Strawberry Leaves.—"O. W." The old spotted leaves seen on strawberry plants after the fruiting season, are those which have performed their office and will ere long decay. There is no need of removing them, as they will soon fall off of themselves, and they are useful as a mulch; the more of them on the ground the better.

Exterminating White Daisy.—"W. N. P., of Hyde Park, Vt., asks what to do with this pest "after it has got a start," and if the seeds can be killed in manure. It should not be allowed to "get a start" anywhere, as many farmers in western New-York, can regretfully testify. Constant cutting or pulling before a single plant blooms, in field, fence corner, or road, will in time worry it out, and this should be done—always done with this and other pests. Thorough composting and fermenting of manure will destroy the vitality of all seeds.

Book on Carpentry.—"C. L. L.," Clay Co., Ind. We know of no popular book on carpenter work adapted to general use. There are some expensive books on Architecture, suitable for professional master-builders, or those following the business. Native tact, and practice with common tools, will suffice for all ordinary operations; beyond these, as in the erection of buildings, it is cheaper to employ an experienced mechanic.

Stove Cement.—A very good cement for stopping cracks in stoves or pipes is said to be made by mixing iron filings white lead, and linseed oil together, to the consistence of putty. Apply to the joint or crack, and leave for a day or two before heating up the stove.

Cotton in Illinois.—According to estimates by sundry newspapers in Southern Illinois, the produce of cotton in the Southern counties will not fall below, but probably exceed 25,000 bales, or over 10,000,000 lbs. They further state that much more would have been planted could good seed have been obtained in season. These guess-work estimates may be far above or below the truth, but we doubt not there is enough growing to test the practicability of cotton culture north of the Ohio river. We solicit information from the readers of the *American Agriculturist* in that region.

Cotton-Growing Next Year.—James Coulter, Sen., Randolph Co., Ill., writes that he intends to plant seventy five acres in cotton next Spring. He is confident that it can be grown in that latitude successfully.

Tobacco in Wisconsin.—"H. W. A.," Milwaukee, Wis. We have seen a good growth of tobacco in southern Wisconsin. It will do well where Dent corn will. There are no books on Tobacco Culture in the Northern States.

"Holding the Reins."—"O. L. G.," a young reader of the *American Agriculturist*, at Buffalo, writes that while he was pleased with our illustrated article in May, on "Holding the Reins," he yet thinks he has a method superior to that. He writes as follows: "As I am no draughtsman, I will illustrate my ideas in this way: Take a pair of shears and open them wide, then grasp them with your hand around the crossed blades, and you will see my way of holding the reins. You have the reins crossed in the palm of the hand, and the fingers closed over them. Thus you have them held firmly, and you get a purchase which you can not have in most of the ways mentioned in that paper." His method is not altogether new, but we publish it to encourage him and others to think and practise on the various subjects presented.

Best Eyes in Potatoes.—J. B. W. writes that the eye nearest the stem of potatoes sends up a sickly shoot, and is unreliable. He has made extensive experiments this season. The center eye on the seed end grew the quickest, and produced the earliest potatoes.

The Fork Better than the Spade.—"Rustic." Not always. You could not make mortar with a forked spade. So in ditching, moving gravel, or sand, and in doing such like work, the time-honored spade and shovel will hold their old place. Yet, for some garden operations, the fork is preferable. In breaking up the soil of a garden in Spring, when the ground is a little over-moist, the fork will disintegrate it, when the spade would only make it a hard, compact mass. So in working among the roots of choice trees and bushes, the fork will do less injury to the tender roots, and at the same time be equally serviceable in loosening the soil.

Cook's Evaporator.—In our report of the Michigan State Sorgho Convention, we spoke of the first premium having been given to 'Cory's Evaporator.' It should have read "Cook's Evaporator with Cory's Improvement." The mistake occurred in the official report of the meeting. The improvement consists of a high ledge across the pan, with a gate for the more ready control of the stream when used without rockers upon a brick arch. Messrs. Blymyers, Bates & Day furnish their stationary pans with high ledges and gates, without extra charge. We learn further that all Mr. Cory's Evaporators are manufactured by them.

Clearing Ground of Hazel.—T. J. F. Healey, Whiteside Co., Ill. Your query seems to be answered by another correspondent thus: "Cut the Hazel in July or August, or even early in September, with a bush scythe; burn over if it can be safely done, and plow at once where the roots will admit. If it can not be plowed, sow with winter rye, and harrow in, plowing it another season, when many of the roots will be decayed.

Changing Seeds.—W. F. Troxell, Lehigh Co., Pa., recommends changing vegetable and other seeds every few years. His experience is, that they deteriorate if kept upon the same soil for three years, and that heavy or clay lands retain the seeds, or the vegetables they produce, in good condition, longer than light, loamy soils. He would never select seeds from a rich soil to be sown upon poor ground, but the contrary, when practicable.

Work for Children—Where Borers Work.—George A. Grataeap, Westchester Co., N. Y., writes: "My fruit garden of three acres is divided into three districts, and one child is appointed to each, with a reward allotted for each borer. Five or six times during the past two months, I have cut out, from one tree in one day, as many as ten young borers, most of them from 4 to 10 feet from the ground, and in or under the fork of branches. I have seen but two or three woodpeckers in these ten years. (More chance of course for the borers. Ed.) Within fifteen days after reading 'Remedy for Borers' in the July *Agriculturist*, I found one in a small uncovered root of about 1¼ inch in diameter."

Companies for Government Lands.—Jas. Lamport, Rush Co., Ind. We believe companies are forming in various localities, to take up Government lands, and form communities of acquaintances, but cannot point to an individual one just now. Such a company may perhaps be formed from your vicinity.

Large Tomatoes, Poultry-Manure.—We have received specimens of tomatoes weighing 1 lb. each, from J. Davidson, of Washington Heights, N.Y., who attributes his superior success in raising, to following the advice given in the July *Agriculturist*, viz.: watering the ground around, and manuring the plants with a solution of 1 shovelful of hen-droppings to 8 gallons of water. The same liquid manure proved equally efficacious on other plants.

Fruit in Wisconsin—Naming Varieties.—G. W. Hyer, Green Lake Co., writes to the *American Agriculturist*, that after much trouble in finding varieties of fruit that will stand the severe winters, cultivators in that neighborhood have at last secured a large and well selected stock. Grapes, particularly, promise finely this year. He says there is much difference of opinion in naming varieties of fruit grown there. If the sorts are of known kinds, Downing's Fruit Book, and other standard authorities will settle these questions. If new seedlings are to be named, they should be submitted to the judgment of experienced fruit-growers to decide upon their merits. Many specimens of natural fruit *ought* to remain nameless and unknown.

Scraping and Washing Trees.—"T. D., Syracuse." The reasons commonly given for this practice is, that trees with clean and smooth barks look well, and that insects lodge in rough barked and mossy trees. This is doubtless so; yet, is it not also true that nature gives the rough bark on purpose to shield the tree from the vicissitudes of climate? We would not advise severe scraping—nothing more than enough to dislodge vermin, and after this, let strong soap suds be applied. Follow this up with a little manure over the roots, and a moderate stirring of the soil.

Leaf Blight on Pear Trees.—Charles O. Newton, Cortland Co., N. Y. The leaves you sent are affected by what in this section of the country is called leaf-blight. It injures the leaves of seedling pears to so great an extent, that nurserymen in this vicinity are almost abandoned growing seedlings for stocks. They now import stocks mostly from Europe, or obtain them from parts of the country where they are not affected in this manner. The blight usually attacks the leaves in July, and always first those upon the last or previous season's growth. It does not kill the stock or tree at once, but gradually weakens it, and unless a favorable season should intervene, it will eventually destroy the tree. Ashes and bone are perhaps the best manures to apply to pear trees that are attacked by leaf blight.

Sour Rough, or Summer Pippin Apple.—J. C. Hart of Westchester Co., N. Y., sends fine specimens, and thinks this variety is not sufficiently disseminated, as he finds prominent fruit-growers do not know it, nor is it in many of the nursery catalogues. Downing describes it correctly in his last Fruit Book, and justly calls it a valuable fruit, ripening from the middle of August to the middle of September.

How the Sap Overcomes Obstructions.—Wrap a tape tightly around a thrifty clon, so as to impede the circulation, and the bark will grow from the top of the tape downward until it unites below. W.

How to Preserve Wood Mosses, etc.—Miss L. W., of Central Ohio, wishes the information. There is a great and varied beauty in the fragile forms of our many colored wood mosses, well worth preserving. Simply dried and preserved under glass, or where dust will not get upon them, and arranged in fanciful and tasteful figures, they are very pretty.

Transplanting Old Grape Vines.—W. Borgeaman, Leavenworth Co., Kansas. We advise early Fall planting of old vines in preference to leaving them until Spring. If the vines are quite large, better layer them, and when well rooted, plant the layers.

Aphis on Grape Vines.—S. French, Lorain Co., Ohio. The "plant lice" are sometimes troublesome by sucking the juices from the tender grape-vine shoots. Dipping the ends in a strong soap-suds, where it can be done, is a good remedy; otherwise syringe with a strong whale-oil soap solution.

Saving Strawberry, Raspberry and Blackberry Seeds.—W. C. Potts, Rice Co., Minn. Save strawberry, raspberry and blackberry seeds, by mashing the berries as soon as ripe, and washing out in water. Put the seeds in boxes of earth and keep moderately dry until Spring, then plant ½ inch deep in light soil.

Strawberries and Raspberries for a Family.—J. D. Henkle, Piatt Co., Ill. For family use, we advise planting the Triomphe de Gand strawberry, and Hooker, or Wilson's, if more than one is wanted. The Fastolf will suffice for a raspberry; Brinckle's Orange, and improved Black Cap may be added.

Large Blackberries.—Mr. C. Rivinius, of Morrisania, N. Y., has placed upon our table the largest and finest New-Rochelle blackberries we have seen this season. Three of them weighed a full ounce, and they were also juicy, *sweet*, and fine-flavored.

Prolific Currants.—F. Trowbridge, writing from New-Haven Co., Conn., says Deacon E. Newbury picked 19 quarts of cherry currants from 5 bushes, and challenges a better yield.

Two-Story Roses.—C. M. Morton, Mercer Co., N. J., sends to the office of the *American Agriculturist*, specimens of roses, from the center of each of which a stem rises bearing another perfect flower. In some cases a stem has risen from the second flower, and borne a third rose. This curious habit may become fixed in a variety, so that it will always produce flowers of the same character. Such instances are not common, although there are varieties of roses that often produce buds from the center of the first flowers, which afterward come into bloom. The Yellow Tea Rose, sometimes called *Smithii*, often produces flowers of this kind.

A Floral Question.—G. H. H., Madison, N. J. It is affirmed by some writers that the reason why we have no blue rose or blue dahlia, is because the rose and the dahlia, in their original wild state, had no blue or any combination or shade of blue in their flowers. And they say that the French florists may hybridize till they are blind, and yet not be able to get a color into a variety of plants which did not exist in the original species. We have made this statement before, on the authority of another, but can not vouch for its truth. It is, however, certain, that in the dahlia we have fine purples, and a very near approach to blue. So in the rose, *La Tourterelle*, for instance, popularly styled the "dove-colored rose," we have a slight shade of blue. In the hyacinth, as you observe, we have all the primary colors, with various shades and tints of the same. The question is a very interesting one, and is open for experiment.

Best Petunias of 1862.—"Jane." *Prestidium*, double, pale rose color. *Lizzie Reed*, single, striped white and crimson, of medium size. *Marguata*, single, deep crimson, tipped with white, large and very fine. *Captivation*, double white. *Zouave*, resembles *Marginata*, but smaller. *McClellan*, double crimson, tipped with white. *Countess of Ellesmere*, bright crimson, with white throat, very good.

Polygonatum *multiflorum*, or Solomon's Seal, appears to be the name of the wild flowers sent by C. Hoffman, Dauphin Co., Pa.

Sarracenia Purpurea for Small Pox.—This is our native "Pitcher Plant," and is said to be a remedy for small pox in all its forms, in twelve hours after the patient has taken the medicine; that, "however alarming and numerous the eruptions, or confluent and frightful they may be, the peculiar action of the medicine is such that very seldom is a scar left to tell the story of the disease." If either vaccine or variolous matter is washed with the infusion of the Sarracenia, it is deprived of its contagious properties. So mild is the medicine to the taste, that it may be largely mixed with tea and coffee, and given to consumers in these beverages to drink without being aware of their admixture. The medicine has been successfully tried in the hospitals of Nova Scotia, and its use will be continued.—So says the *Gardener's Monthly*.

Hibiscus.—The leaf sent by a subscriber in Marion Co., Ohio, is from the common shrubby Althea, the botanical name of which is *Hibiscus Syriacus*.

A "Quarter" of Grain.—In the English markets, grain is quoted by the "quarter," and the prices in shillings Sterling. The quarter contains 8 Imperial bushels, or 8¼ American bushels. (33 American or Winchester bushels equal 32 Imperial bushels). The English shilling equals about 24 cents and 2 mills. For a rough calculation we may reckon the Sterling shilling at ¼ dollar, and to reduce London rates to New-York bushel prices, divide the quoted shillings per quarter by 33. The telegraph reports a certain grade of wheat in London at 57*s.*—that is, 57 shillings, or $14.25 per 8¼ bushels. Or, dividing 57 by 33 gives about $1.73 per bushel. From this we deduct freight, waste, insurance, commissions, etc., to get the corresponding price in New York. When Flour is quoted by the barrel, we have only to divide by 4 to get the price in dollars, nearly. (Just now, four shillings sterling are equal to considerable over $1, owing to the price of gold, and the cost of exchange.)

Inches in a Bushel.—"New Subscriber," will find all he desires to know on page 136, Vol. 18, of the *Agriculturist* (May 1859). The American bushel contains 2150½ cubic inches (or exactly 2150.42). This is the old English Winchester bushel. The new English Imperial bushel has 2218 1-5th inches (or exactly 2218.192). A box one foot square, inside measure, requires to be very nearly 7½ inches high inside to hold ½ bushel, or about 15 inches high to hold a bushel (exactly 14.93 inches). A box 15 inches square and 9½ inches deep, holds very nearly a bushel. The exact depth is 9.55 inches. A box containing 56 cubic feet holds 45 bushels of grain. To get the bushel contents of a box: multiply its inside length, breadth, and hight together; multiply the product by 45 and divide this by 56. To get the size of a box holding any number of bushels, multiply the bushels by 56 and divide the product by 45, and you have the number of *feet* required. The hight will depend upon the length and width. *Example:* For 100 bushels, multiplying 100 by 56 and dividing by 45 gives about 124½ for the feet required. This is almost exactly 5 feet every way.

Nepaul Barley.—P. Adland, Racine Co., Wis. The barley sent is the above variety, figured and described on page 261, September No. of last volume. We distributed seed of it last Spring. See seed No. 190, with a brief description on page 4, January *Agriculturist.*

Hop Vines for Grain Binding.—The Maine Farmer suggests the idea of cutting hop-vines into suitable lengths, and storing them until next harvest, to be used for binding grain, corn stalks, etc.

Diseased Cattle.—George D. Sylvius, Susquehanna Co., Pa., writes that he has had several young cattle affected with a singular cough, which caused them to pine away, and one of them has died. On examination a large number of fine white thread worms were found in the windpipe and lungs. He would like a remedy.

Fatten Stock Early.—"J. W. B.," Madison. It is well to begin to fatten stock just as early as it can be uninterruptedly pushed forward. Irregular feeding is very bad. The feeding of grain or oil-cake should begin early, and with comparatively small quantities, and it should be gradually increased as the condition and appetites of the animal indicate. Quiet is an important element in successful management of fattening cattle.

Kicking Cows.—Take a hoop or strap of proper size, double the nigh fore leg, and slip it over the knee, past the pastern. She will stand and can not kick.

Weight of Cattle by Measurement.—J. L. T. will find no definite rule. Some cattle are long and tall, while others are short, thick, and deep. An animal girthing 8 feet ought to dress about 1,000 lbs.

Sick Hens.—I have seen chickens with a disease, the symptoms of which were similar to those described in the June *Agriculturist:* Fluid discharges from the nostrils, with a formation of something like a tumor, commencing in the corner of the eye, extending backward, and finally implicating the substance of the eye; blindness and death the result. I saved a few by repeatedly removing this formation, but tried no internal remedy: I disengaged it with a sharp instrument, and removed in sections: It would re-form, but yielded to persevering removal. J. B. W.

Keeping Vermin from Roosts.—A. J. Aldrich, of Mass., has adopted the following effective plan for protecting poultry roosts from vermin: A narrow groove, say three eighths of an inch wide, is cut in each roosting pole running the whole length. This groove is filled with oil or lard, which soon destroys lice on the roost. A small portion of it also will be rubbed upon the hens and thus expel the vermin. Snuff has been recommended for the grooves, but oil is much more effective.

Cleaning the Premises of Fleas.—J. McClure, of Logan Co., O., cleaned his barn from fleas, which an accumulation of rubbish had engendered, by scraping up and carting away all the manure, especially that under the barn, and yarding his sheep around and under the building at night, driving them away to pasture in the morning. He claims that the sheep transported the remaining fleas and left them in the field. Perhaps so.

Currant Bush Insects.—J. Townsend, Strafford Co., N. H. From the number of lady birds, (coccinella) found with the currant worms sent to us, we judge your bushes will eventually be freed from injurious insects. The lady birds, or turtle shaped bugs with yellowish wings, on which are six black spots, are our best friends, as they live chiefly upon other insects, and should never be destroyed.

Insects Multiplied by Fall-Plowing.—The Grant County Witness, Wis., says many farmers there begin to think that by Fall-plowing the eggs of the Hessian Fly and Chinch Bug are securely covered, instead of being left on the stubble to be destroyed by frost. On the contrary, we would inquire whether the eggs are less likely to be destroyed when dry, above ground, than when freezing and thawing in the moist soil? Burning the stubble would kill many insects. What says Dr. Fitch?

Driving Ants from Bee-Hives.—One who has tried it says that fine tobacco scattered about the hives will repel ants. It ought not to be put upon the bee stands, as the bees would be annoyed by so offensive a substance. *If* useful, place it around the supports of the stands, where the ants must climb to reach the hives.

Sulphur for Sheep Ticks.—E. R. Towle, Franklin Co., Vt., says a little sulphur mixed with salt, and occasionally fed to sheep, will certainly destroy ticks, as he has proved by repeated trials. He prefers the sulphur to oil sediment or tobacco extract.

Is Milkweed Poisonous to Bees?—D. Ryan, Armstrong Co., Ill., says he noticed dead and dying bees upon some milkweed, growing on his neighbor's premises, (*he* does not allow such weeds on his own grounds,) and upon examination, concluded that the sweets extracted from the flowers by the bees were poisonous to them. Has any one else similar observations?

A Word for the Blackbird.—F. M. Rogers, Stephenson Co., Ill., thinks the blackbird is unjustly slandered, and that the amount of insects he destroys more than counterbalances the corn he steals. There are two sides to this question.

When to Make Asparagus Beds.—W. Arnd, Cattaraugus Co., N. Y. Fall is the best time to make new beds, say any time in the month of October, especially from the middle to the last of the month. Choose 2-year-old plants if possible. Old matted roots are not as good, but may be used, however, and will yield cuttings sooner; fresh roots probably produce the best permanent bed; they are sold by nurserymen, commercial gardeners, and seedsmen, at $1 to $2 per 100.

Hops.—"G. B. S." Hops may be grown both from cuttings and from layers, and also from the seed.

To Keep Sweet Potatoes.—"R. B. S.," Jefferson City, Mo. When clean and dry, pack them in dry sand, and keep them dry and *moderately warm.*

Winter Covering of Tender Plants.—"Sarah." First, lay around and over the crowns of the plants a few dry leaves, or the rubbish from the garden, then put over them a shovelful or two of dirt. Putting on too much dirt is worse than none.

Transplanting Grape Cuttings.—W. S. Wooton, Howard Co., Ind. Cuttings put in last Spring, if well rooted, may properly be set in the vineyard or other permanent situation this fall. They are sometimes left for two years, but if set after the first season's growth there will be fewer roots to disturb. If purchasing plants, we prefer two year olds, to save time.

Pear Blight.—There are accounts of the prevalence of the black blight in the pear trees of New-England, Central and Eastern New-York, and other parts of the country. Cut, cut: cut: do not spare the knife. As soon as it shows itself, cut off the limb even if it be the best one on the tree. Prevent a recurrence by removing from the tree all manure and mulch after the first of September, if not before, and prune back the tender wood so as to have all the wood well matured. Should shoots of a second growth start, kill them off before Winter and mulch the ground about the trees, but not close to the stems, just before the ground freezes.

Keeping Dahlia Roots.—A Correspondent of the Cottage Gardener having lost many Dahlia roots by the rotting of the crown, discovered that the mischief was caused by the decay of the long stalk left attached to the tuber. The remedy is, to have not more than four inches of stalk; from this to scrape the whole outer covering of bark, and at the base to make a small opening which permits the watery deposit to escape. By this means he has succeeded in keeping the tubers sound.

Handsomely Done.—The Springfield News (Ohio), having copied our "Wheat Article" without credit, in another issue apologizes for the non-credit as an error of the compositor. and says: "We are sorry for the omission, and will try to prevent such an occurrence again, *but if our readers should find an unusually good article in our columns (the News,) without credit, it can be laid to the American Agriculturist.*"—Thank you: the account is more than square.

Coinage at the Philadelphia Mint during July.—During the month of July there were coined at the above mint 3,476 double-eagles, 20,960 quarter-eagles, 5,000 silver dollars, 52,800 quarter-dollars, and 3,600,000 cents, making a total of 3,682,236 coins.

Hohenheim Agricultural College.

One of the most interesting points visited during our recent journey abroad, was the Agricultural College at Hohenheim, six miles south of Stuttgart, the Capitol city of Wurtemburg, Germany. (Stuttgart is, by R. R., 125 miles S. E. from Frankfort.) We brought home some documents in German intending to write out a more extended account of this Institution, with the assistance of our associate Mr. Weld, who had previously made a more lengthy visit there. Owing to Mr. Weld's absence as a volunteer in the army, we delay the account for the time being, but will say in brief that this is one of the most complete schools of the kind in the world—the largest and best, we believe. The buildings are extensive, being the former Royal Palace, and the farm contains about 1000 acres. The cultivation of the farm is under the care of the Professors, and its proceeds, together with an additional allowance by the government, are devoted to the support of the school. Large plots are appropriated to important experiments with various crops, manures, etc. A manufactory turns out improved implements for the College farm, and also for introduction into the country. The best breeds of animals for the country are multiplied here in purity, and scattered among the land owners. The cabinets and museum are supplied with specimens of animals, including their skeletons; samples of implements of various countries, including all the plows in use in ancient and modern times, and in different nations; specimens of all the soils in the kingdom, in layers showing the upper and subsoils, and the rocks from which they were formed, also of artificial fertilizers; samples of various grains and grasses, weeds, of wools, etc., etc.: all varieties of horse-shoes, the bones of the feet, diseased limbs, etc. An artificial cow with the organs of parturition is used in the demonstrative lectures.—Some of the above we may perhaps describe more particularly hereafter, in separate notes. Students of all ages and degrees of advancement are received, and put into such courses of study as may suit their several ages, amount of previous knowledge, time of study, and especially their intended future occupations in life.—The cost for tuition, room, apparatus, and for all expenses, exclusive of board, is 300 Thalers a year (about $200). Board is obtained cheaply at restaurants in the buildings, in the European style, each article called for at every meal being paid for at moderate rates. We are under special obligations for the kind attention shown us by Professors Dr. Emil Wolfe and Dr. L. Rau, the former in charge of the chemical department, and the latter of the farm, implements, animals, museums, etc. Dr. Rau is the author of several treatises, and is enthusiastic in collecting the best animals and implements. His collection of plows, above referred to, is alone worth a long journey to examine. He has samples of our best American plows, and is aiming to improve upon them. American farmers or agricultural students going abroad will miss a great treat and much useful observation if they fail to make a long visit to Hohenheim. We regretted being hurried away so soon by the (false, London-vamped) unfavorable war news from home. Neither in Wurtemberg, nor in any other part of Germany we visited, is an American annoyed as he is in England, by hostility to or lack of sympathy with his own country.

Crop Reports for September, 1862.

Yield, Breadth, Condition, and Prospects of the Principal Crops in all the Northern States, for the Season of 1862. Reliable Reports from all Sections of the Country, Gathered Specially for the American Agriculturist.

Most important information is supplied on pages 314 and 315, of the *American Agriculturist* for October. The figures give in condensed form, the estimates of nearly a thousand careful, observing, practical, and reliable men, most of whom were selected to gather these reports from their peculiar fitness to aid in the enterprise, and their opinions and estimates are specially valuable. Each figure expresses a whole paragraph. The following summary will be useful to those who can not study the reports.

THE WEATHER (*Column A*).—The average for the whole country for a month ending Sept. 10th, is **9.8** (10 being the average for the same period during five years past). The average is lowered by drouths in some parts of Pennsylvania, Ohio, Illinois, etc., as indicated in the tables. In the northern tier of States, the weather reports are very favorable, averaging above 10.

WINTER WHEAT (*B*).—The gathered crop averages for the whole country 12½, that is, 25 per cent. above last year. As compared with the average of five years past, the figures (under *C*) are 13.9, or 39 per cent. higher. The best reports are from the great wheat States, Ohio, Indiana, Wisconsin, Michigan, etc. There can be no further doubt that, taking the whole country together, the aggregate yield of winter wheat this year exceeds that of *any* previous year.

SPRING WHEAT.—The gathered crop, in the counties reported from, averages 38 per cent. above last year, and 70 per cent. above the average for five years past. But from the limited number of reports from localities where this crop is most grown, and from the small yield in those localities, we judge that the *total* yield for the whole country is below that of last year.

INDIAN CORN.—The reports make the total area planted average about the same as last year, and 12 per cent. above the annual average for five years past. The prospective yield per acre on Sept. 10th, was a trifle below the average, taking the whole country together. In the great corn-growing State of Illinois, the good corn weather (except in a few counties where it has been too dry) has brought forward the crop so well as to promise nearly an average yield per acre. Owing to drouth, the reports from Ohio and Pennsylvania average poorly. If frosts hold off late, in the northwestern States where the growth is very fine, the total crop of the country will be fully equal to last year, taking into account the larger area. Early frosts would, of course, reduce the yield. On the whole, the prospect is good for a large corn crop.

RYE.—The reports indicate that the total yield this year is hardly up to an average.

OATS.—After a careful examination of all the reports received, and taking into account the area and yield where this crop is most grown, we conclude that the total product is just about an average. The aphis was very destructive in some localities, but not generally.

HAY CROP.—A few counties are reported to have a short supply, in southwestern New York for example; generally, there is an abundance.

POTATOES.—The reports indicate a general good crop. In parts of Ohio and Pennsylvania, potatoes have suffered severely from drouth. The "rot" is alluded to in a single instance only.

FRUIT.—Apples, Peaches, and Pears, and Plums wherever grown, are very abundant and very good. In a few counties in Ohio, they are reported deficient. For the whole country, many reports indicate that apples are nearly double the usual crop, and peaches nearly quadruple.

BARLEY has turned out very well in all places reported from, except in three counties.

FLAX, has been more widely cultivated than usual, and the prospects fully equal other years.

COTTON.—Several reports from southern Illinois and Indiana, speak very hopefully.

BEANS.—The demand for army food led to a large increase in the area planted, and numerous reports indicate a good yield.

CLOVER SEED, is largely grown in Bedford, Columbia, Franklin, and Montgomery Counties, Pennsylvania, and our reports from those Counties are very favorable. Little has been heard from other sections of the country.

HOPS and TOBACCO.—So far as reported, these were promising well in most localities.

SORGHUM.—Reports are very favorable from almost the entire West. The area is large, and growth of cane vigorous—better than usual.

The Foreign Demand for American Breadstuffs—Practical Hints.

Last Winter and Spring, the prospect was, that after the harvest of 1862, the large foreign demand for our breadstuffs would nearly cease. It was certainly to be expected that after two short harvests, and with the extraordinary breadth of winter wheat sown in good condition last Autumn, this year would witness an abundant supply in England and on the Continent. But the result is, (happily for *us*) quite otherwise. Every succeeding week's intelligence brings out this fact more clearly. As one certain indication, we may note that in London, wheat and flour are considerably higher than they were last year, and during the early summer of this year. It is now evident that, owing to continuous rains all through the early summer, the wheat straw in Great Britain made a poor sickly growth. On this point we are positive from our own observation. Such straw could not yield large heads of plump grain. The best authorities, and reports from hundreds of careful observers in different parts of the kingdom, admit a yield quite below the average. In France, and in Central Europe, the wheat crop is not above the average—rather below if anything. The condition of the wheat crop in Portugal, and probably in Spain, is sufficiently indicated by the fact that the Portuguese Government has taken the unusual course of throwing open the ports of that country to the *free* importation of breadstuffs. Official announcement of this was made to our Government through the Portuguese minister at Washington, a few days since. In short, the whole tenor of our recent advices from the other side of the Atlantic, is, that there will be a steady demand for all the breadstuffs we can spare from our crop of 1862.—From what we can gather, the breadth of wheat sown in our own country this Fall is not large, owing mainly to the scarcity of labor. It becomes us to consume corn largely, and save our wheat for market. It will be well, also, for farmers to plan for a large surface of Spring Wheat, wherever it can be grown with advantage. As much ground as possible should be broken up before the ground freezes. The action of frost upon new-plowed land is very useful, and the soil broken up now will be in condition for working earlier in Spring.

Exports of American Breadstuffs—Interesting and Important Statistics.

What is termed the "Grain Year" closed on the first day of September, after our last issue of the *American Agriculturist* had gone to press. In our Market Review, on page 316, will be found carefully prepared, condensed tables showing some statistics that will be of great interest, not to farmers alone, but to all classes. Probably few persons fully appreciate how much the facts indicated by these figures have had to do with the support of our country financially, during the past year of war. At the beginning of the war we were largely indebted to Europe for previous importations of merchandise, and for American securities held there; and we have since necessarily imported large amounts of war materials, guns, clothing, and other accoutrements for soldiers. Formerly our imports were mainly paid for by exporting cotton. When this was stopped, it might well be feared, and indeed it was expected by those in rebellion, that our country would be largely drained of gold and silver to pay up debts already incurred. But, as Providence ordered it, no sooner was the North in this financial danger, than relief was provided. Our fields yielded bountifully, while the European harvest partly failed.——Reducing flour to its wheat equivalent we have the following figures:

Exported from the United States to Europe.

Year ending.	*Wheat.*	*Corn.*
Sept. 1st, 1859	1,736,080 bushels	367,520 bushels
Sept. 1st, 1860	8,943,740 bushels	2,291,215 bushels
Sept. 1st, 1861	43,525,116 bushels	11,806,179 bushels
Sept. 1st, 1862	50,190,160 bushels	15,697,094 bushels

Or adding together Wheat and Corn, and comparing the present and past year, with the previous two years, we have these contrasts:

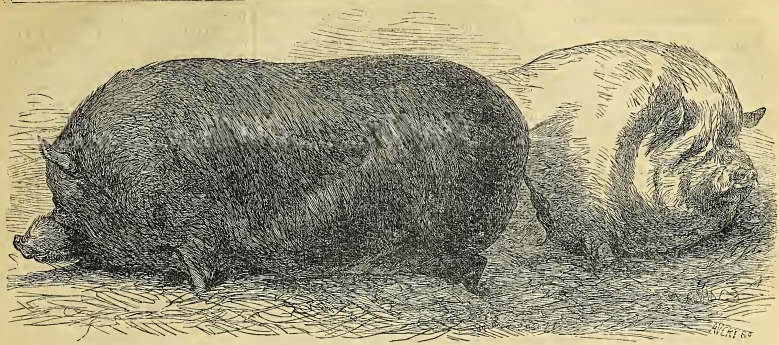
Wheat and Corn exported 1859–60.... 13,288,567 bushels
Wheat and Corn exported 1860–61.... 121,188,499 bushels

Thus, then, the exports of two kinds only of grain, have during two years past amounted to over *One Hundred and Twenty Millions* of bushels, worth at least, **150 million dollars**, all of which has gone where gold would otherwise have gone. (We have not referred above to exports to South America and the West Indies, which have been quite large comparatively.)

And not less remarkable is it, that this third grain year opens with prospects similar to the last two. The N. Y. City *sales* of Flour, Wheat and Corn, for the month (26 business days) ending September 19, stands thus:

	Flour, bbls.	*Wheat, bush.*	*Corn, bush*
1862	513,000	5,482,000	3,065,000
1861	514,000	5,279,000	4,270,000

The tables of exports for September of this year are not yet made up, but they correspond with the sales. The probability of the continuation of this large volume of trade in breadstuffs is discussed in another item.—Table 4, in the Market Review, shows that during 16 years past the *total* shipments to Great Britain and Ireland have differed but a fraction from 100 million bushels of Corn, 100 million bushels of Wheat, and 2½ million barrels of Flour (equal to a trifle over another 100 million bushels of wheat.) The other tables on page 316 are also interesting, showing, among other things, the volume of business in Breadstuffs at Chicago.



PRIZE SWINE AT THE ROYAL AGRICULTURAL SOCIETY'S EXHIBITION.

Engraved for the American Agriculturist.

Above we present excellent portraits of two of the prize hogs, shown at the recent Exhibition of the Royal Agricultural Society in London. The one in the foreground is the Berkshire boar "Lablache," the property of the late Sir Robert G. Throckmorton. All the good points of this excellent breed are well brought out. We see the small head and ear, the fine bone, compact carcass, and deep hams, which have so long made the Berkshires a favorite breed in England. In our country, of late years, the larger framed swine have attracted much attention. Their average weight may be greater than that of the Berkshires, but it may be doubted whether they will give a larger return of meat for the amount of food consumed. In this particular, the Berkshires stand very high. Specimens of great size have been raised. One is noted by Youatt, which measured seven feet seven inches from the tip of the snout to the root of the tail, and seven feet ten inches in girth round the center; five feet round the neck, and two feet across the widest part of the back. He stood three feet nine inches high; and what was most remarkable in this monstrous animal, he did not consume more than two bushels and three pecks of ground feed per week. Their ordinary weight, however, averages from 250 to 300 pounds. It is not always desirable that animals should attain such unwieldy proportions. For eating, the same amount of meat from two animals weighing 300 lbs. each, would be worth more than from a single one of double size, because the quality would be superior.

The second portrait in the above engraving is of the sow named "Silverwing," belonging to Mr. Wainman. She was the winner in the class of "sows of small white breed."

Making Game of Chickens.

It is generally known that the flavor of meat depends largely upon the kind of food on which the animal was fed before being killed. Fowls allowed to pick up their living from offal and filth yield flesh greatly inferior to that made from clean grain and other wholesome food. The spicy *game* flavor of partridges and other wild fowl is due to the aromatic nature of the berries and buds on which they subsist. As it is easy to regulate the food of domestic fowls, it is worth experimenting upon whether any desired flavor can not be given to the meat.

The Scottish Journal of Agriculture advances the opinion that this is possible. The chickens might not relish the food necessary to impart the flavor, but under the system of artificial feeding common in Europe this would be no hindrance. In France, fowls are fattened by pouring farinaceous food in a liquid state down their throats through a funnel made for the purpose, and it would be easy to impregnate the mixture with any oil or essence required. This would be necessary to be done for only a few days at the close of the fattening process, so that the health of the fowl need not be impaired.

To Keep Ice Cheaply.

A supply of ice to use through the heat of Summer contributes to profit as well as luxury, and a receptacle in which it may be kept is not necessarily expensive. The main essentials are: 1st, an outside shell, with from eight to twelve inches of clean sawdust, or other dry porous material; 2nd, protection from the direct rays of the sun; and 3d, a pipe through which to drain off or pump out any water that may collect at the bottom. Ice has been kept through the season in an enclosure made by notching long rails and laying them up like the outer walls of a log-house, in a position entirely protected from the sun. The ice was cut in large, solid blocks, packed closely, and water turned on to each layer and allowed to freeze solid. A space of ten or twelve inches between the ice and rails was filled with sawdust, and the whole was roofed with boards, with plenty of sawdust between the roof and ice. This was entirely above ground. Ice has also been kept in a similar structure one half underground. One who tried this four years failed at first because he used straw instead of sawdust for filling in around the ice. When he relied upon six inches of sawdust he had perfect success. The walls of his ice-house were made by setting common studding upright and boarding up each side of the studs, filling the space between with sawdust. Another has succeeded well by excavating —including the embankment made by the soil thrown out—about twelve feet in depth, then laying up a stone wall, dry to the top of the ground, and in mortar the remaining distance to the top of the embankment, covering the whole with a good roof. All that is necessary to success in keeping ice is fully stated in the first part of this article, and each can best judge for himself as to what particular style of structure will best suit his individual circumstances.

Experiments in Rotting Flax.

A Canadian gentleman, interested in flax-culture, writes from London under date of July 17, as follows, relative to experiments in rotting flax: "I wished particularly to ascertain the difference in value between dew-rotted flax and that steeped in the ordinary manner in cold water—and I was shown the result of a most interesting experiment on this very subject, tried this year. Flax taken from one field was separated into three portions—(1) one of these was dew-rotted, according to the custom of the country where it was grown (the grower thinking the quality not good enough for any other system)—(2) the second was rotted in stagnant water in pits according to the custom in the North of Ireland, and in many parts of Belgium—(3) and the third in running water, as practised in the river Lys at Courtrai. The last was the best flax when rotted, but the second was actually *double* the value of the dew-rotted flax.

"This circumstance should be known by our farmers, as the same crop may be made to yield a two-fold value according to the system of rotting practised; and in point of fact the steeping system—occupying only 6 or 8 days, is cheaper than dew-rotting, which occupies six weeks or two months, and must therefore require a greater amount of supervision."

By the way, we hope some process will soon be discovered for using flax for paper. The white paper on which the *American Agriculturist* is printed, contains a considerable amount of linen, in order to give it great strength for preservation in book form, without increasing the weight and postage. This makes the paper much more expensive than that for common newspapers that are to be used once and then thrown aside. Such paper can be manufactured of old cotton rags, with a considerable admixture of clay or plaster to give it thickness and weight without increasing the strength.

Plowing—Fall or Spring.

This question is discussed every year, yet remains more or less unsettled. We do not now expect to dispose of it effectually, but simply to suggest a few hints worthy of consideration.

No one can deny that fall-plowing saves time for doing other work in the busy season of Spring. Moreover, the soil is drier in Fall than in Spring, and so is in a better condition for working. He who has waited week after week for the spring rains to pass over and the ground to settle, will feel the force of this consideration. Again, if a piece of land is infested with grubs or other vermin, or with the roots of weeds, there is hardly a better way to subdue these pests than by throwing them up to the surface just before the winter frosts set in. Grasshoppers, the midge, and weevil, can not thrive much after turning their houses topsy-turvy in October and November. They can not rebuild in Winter, and many of them will be killed outright. For light, sandy soils, apt to blow about in open Winters, or those which are quite gravelly and porous, we question the expediency of fall-plowing. But for stiff clays, which need the action of frost to pulverize them, this is the best treatment that they can receive.

A friend in Wisconsin writes us, that in all his region the farmers do as much fall-plowing as they can, finishing up the balance in Spring. That then, they sow and harrow all together at the same time, and that in the Summer no one can see any difference between the growth and yield of the several fields; at harvest time, perhaps, the spring-plowed land is more mellow than the fall-plowed, but the grain is worse lodged. A correspondent of a western journal claims that for spring wheat and barley, fall-plowing is much preferable. He thinks that spring wheat grown on fall-plowed land, yields a better and surer crop than winter wheat sown in October. "The exposure to atmospheric influences during the Winter, mellows and enriches the seed-bed to such a degree, that whenever the grain is sown, it has the elements which it needs at hand ready for assimilation.....The soil newly turned up, has first to be prepared or mellowed, *oxidized*, as the chemists would call it, before it becomes fit to yield nourishment; and while this process is going on (in Spring,) much precious time is lost, and the growth of the plant is abbreviated in proportion, its time for tillering is cut short, and the yield can not be as large as when it has the whole length of the season which nature seems to have set apart as that in which the plant shall make stems and leaves, previous to the formation of the seed-vessels."

This certainly can be said in favor of the fall-plowing of sward land intended for corn. If it is done early in the Autumn, the sod becomes partially rotted before the time comes for planting, and so is sooner prepared to act as a fertilizer for the crop, than it would have been if plowed in the Spring. If ever the plant wants the food of the decayed sod, it is early in the season, to give it a quick and vigorous start.

Late planting is a frequent cause of the failure of crops. After they are got into the ground, a drouth often sets in which retards the germination of the seed. We plant late, because the cold rains put us back, and because of the pressure of other work. Now, if we should do much of our plowing in the Fall, we could take advantage of the first favorable weather to get our seeds in, and so gain considerable time in their growth. If we postpone all our plowing until Spring, we often do the work when the land is too wet: the consequence is that it becomes lumpy and stiff-baked—a condition unfavorable for the growth of any crop, and from which the land does not fully recover in a season or two.

Three Golden Rules for Cultivators.

They are golden because they will bring the gold. Read them: 1st, *Make manure;* 2d, *Save manure;* 3d, *Use manure.* If the first two can not be practised, which is hardly a supposable case, or if they do not give sufficient results, then follow the silver rule: '*Buy manure.*'

There are several sources upon which farmers may draw for a home-made guano, scarcely inferior to the imported, or manufactured fertilizer. They can get ammonia much cheaper in the home-made article, than to purchase it. The basis of the manufacture should be dry muck or peat; or if these can not be had, dry black loam from the surface of an old field or meadow. Put one or two cords of this under a shed, or in any dry place, and leach liquid manure through it. This may be slops from the chamber and kitchen, or from the stables and yard. The loam in the heap will absorb all the fertilizing matter in the liquid manure, and the water will pass off into the ground. It will of course grow richer the more liquid manure it receives. About a month before it is wanted for use, stop watering it, and turn it over with a shovel or fork, making it as fine as possible. If it be turned two or three times it will be all the better. A handful of this in the hill will promote the rapid growth of all garden and field crops.

With the same basis, ammonia may be furnished very cheaply, by mixing night soil with the muck. If in a wet state, it may be mixed load for load, and after lying two weeks be overhauled, and more night soil be added. If free from liquid the mixing in equal parts will make the compost sufficiently strong. Hard coal ashes are a very good absorbent, and may be substituted for a part of the muck. The excellence of this fertilizer will depend somewhat upon the thoroughness of the mingling of the particles. If this be overlooked, it may in some cases destroy the seed, though the danger will not be as great as in using unmixed guano or superphosphate in contact with the seed.

An excellent method of saving and using this article in an inoffensive manner is as follows: The vault of the privy should not be very deep. When once cleaned, throw into the bottom a layer (say a foot thick,) of dry peat, turf, or common soil. Have a heap of similar material nigh at hand, to be used frequently, both in Winter and Summer. This should be kept under cover, and should be so convenient that there will be no excuse for neglecting to use it. Throwing it in once a week in Winter, will do; but as often as every other day in Summer. This will absorb the liquids and keep down offensive odors. Every month or two the vault should be emptied; and where matters are managed as we have suggested, this will not be a very disagreeable job. When the contents have lain in a heap for six months, they may be worked over, and a third more of common soil mixed with them. This will then furnish a rich fertilizer for corn, wheat, grass, cabbages, and indeed for every crop or plant.

Another cheap source of ammonia is the manure of fowls, especially hens and turkeys. No farmer should suffer these deposits to run to waste. Being comparatively free from water, they will make four or five times their weight of loam or muck sufficiently strong for a concentrated fertilizer. The roost should be swept out once a week, and added to the heap. Or if neatness is not so much desired, the muck may be scattered under the poles, two or three inches deep, and stirred with a garden rake two or three times a week, and the whole be cleaned out once a month. This article is conveniently deposited in barrels. This simple fertilizer at the rate of a handful to a hill, will usually add twenty per cent. or more to the yield of corn, or potatoes, in meadow land of average quality. Dead animals are another cheap source of ammonia, requiring a little longer to decompose them, though if they are cut up, they are soon distributed through a pile of muck or loam. They should never be suffered to decay in the open air. By attending to these sources of manure, every farmer may make a concentrated fertilizer of great value. It will turn his leisure time in Winter into money, and add largely to his crops.

Uses of Gypsum.

Gypsum, (or Plaster of Paris), in the opinion of many, is regarded merely as a tonic or stimulant, and by others as a source of inorganic plant food. It is composed of sulphuric acid and lime, two substances which enter into the composition of *all* fertile soils, and into the ashes of all agricultural plants. That this is its great use in the soil can not be claimed, for it is notorious that in many soils which contain an abundance both of lime and of sulphuric acid, and perhaps we may even say, of gypsum itself, a fresh addition of the article produces marked good effects. By this then we are forced to the conclusion that the good effects are not always due to the gypsum simply, but often to those qualities which *fresh* gypsum possesses, and *stale* gypsum does not possess. Gypsum certainly attracts and fixes ammonia; it effects certain chemical decompositions in the soil; it is readily soluble in water, and thus a small quantity of it may be very thoroughly diffused through the soil; on this account a small quantity often produces a maximum effect, and this effect may also be, and it usually is, transient—not lasting more than one season.

It not seldom happens on sandy lands, that plaster operates finely for several years, and then ceases to produce any effect, unless it be to bring in sorrel and mosses. Why so? As yet science suggests no satisfactory reason. When this occurs, a dressing of lime often brings back the soil to a much better condition; but after this has been applied for one or two years, it needs following up with a good dressing of barn-yard manure. In this then, gypsum acts indirectly, and not as the food of plants. Nutriment must come from the manure heap, or green crops plowed under, or both. To rely on gypsum alone, is like giving a hungry man tonics, and withholding food; you stimulate him to death.

This much may be said in favor of plaster, that it generally increases the vegetable or leafy parts of the plants more than the grain, though not to the injury of the latter. By so doing, it increases the bulk of fodder, and thus of manure. If this product is carefully saved and wisely applied, the farm is sure to be improved, and all its productions augmented. Among the many theories respecting the action of plaster, Liebig's is certainly well established, viz: that it absorbs and fixes the ammonia of the atmosphere. And Sprengel's view

is apparently well founded, viz: that it furnishes sulphur to leguminous plants, in which case it acts as plant-food. It is certain that it benefits clover, (a leguminous plant,) more than it does cereal grains or grasses. But there are other facts connected with the action of plaster, which can not as yet be explained by science.

As a general rule, on low, alluvial lands, or those abounding in vegetable mould, gypsum is less effective than on dry, sandy, gravelly soils, or even clay lands lacking vegetable matter. On the latter, its effects are sometimes surprising, almost doubling the crops. Much is said about the best time for sowing gypsum. Whenever sown, it will not be lost; and if applied plentifully, it will last two or three years. But experience shows it to be specially advantageous if spread just before plowing. Sow it from the tail of a wagon, using from two to four bushels per acre, according to the state of the soil. A little observation, from year to year, will show when the land is plentifully supplied with plaster, or when it appears to lose its power of benefiting crops. Indeed, it is only by actual trial that we can certainly know that plaster will be useful on any particular soil.

Another and very important use of gypsum is as a deodorizer and fixer of ammonia in stables, privies, drains, composts, and like places. It prevents the waste of ammonia, and serves to purify many a place which would otherwise be foul and unwholesome. Whenever the manure-heap begins to ferment, let plaster go into it. Whenever a stench rises from stable-floor or barn-yard, let plaster be applied. And whenever that important building, (the compost heap,) goes up, let plaster go into the structure, at the rate of a tun of plaster to a hundred loads of crude manure. There is little danger that gypsum will not generally make good report of itself.

A Hint Touching Manure.

Why do we manure land at all? The majority of soils, as originally constituted, contain all the needful elements of vegetation. Go into a forest: see how the venerable trees shoot up grand and tall; how the vines and under-brush and plants grow in wanton luxuriance. Any need of the dung-cart here? Go out upon the Western prairies, or along the meadows and unexhausted river bottoms of the East. You can run your staff down many a foot through soil teeming with food for plants. Pray, what need again, of the odorous cart? No need, certainly, here or elsewhere, unless to bring back something which thieving man may have stolen.

Cut down an old orchard, and plant a new one on the same site: why do not the handsome little saplings thrive? Because the old orchard has exhausted the land of much of the food which orchards require. No wonder the young trees look so wretched; they are starved.

Crop a piece of wheat land, year after year, without returning in kind what is taken off, and the land will assuredly run out. But if the straw is spread on the land to rot, and if ammonia or other manures, equivalent to what the grain takes away, be restored to the land, it may and will continue productive for an indefinite period. The prairies have grown fertile by the annual decay of their own grasses. The forests grow rich by husbanding the products of the soil.

This, then, is my simple hint. If the land is poor, it must be brought up to a productive state, by manures adapted to its wants. If it is rich, we can maintain its fertility only by restoring to it in kind and measure as we take from it. This, as we understand it, is all "the philosophy and the mystery" of manure, except as it changes the mechanical condition of the soil. Let us never imagine that we can rob ourselves without loss.

Grazing as a Specialty—A Field for "Gentlemen Farmers."

The varied husbandry of the olden times, when markets were few and far between, is fast giving place, in the older States, to particular branches of farming. The division of labor which is carried out so completely upon the large estates of England, is beginning to be understood among us. The system has very great advantages and some evils to counterbalance. If we looked at pecuniary results alone, a single branch of farming can be made more profitable than a dozen different branches upon the same farm. It calls for less capital, and much less skill. On the other hand, a varied husbandry sharpens the faculties, and trains a more intelligent class of farmers. They form a practical acquaintance with a much larger class of objects, and are compelled by the daily necessities of business to a much wider range of thought.

The extent to which the old routine farming has been invaded by new ideas, is hardly suspected by farmers whose journeyings are confined to monthly trips to the nearest market town. In the vicinity of our cities and the railroads that lead to them, we have a large class of market farms, milk farms, and grazing farms. One raises vegetables for the city, another milk, another beef, another hay, and so on, relying upon some one article for all his income.

One of the safest and least troublesome of all these specialties, is the grazing of cattle for the New-York market as pursued in Putnam county, in this State, and the adjoining region in Connecticut. There are some peculiarities in the mode of grazing in this region, that we have never met with elsewhere. The cattle are not raised upon the farms where this method is followed. It is found upon experiment that hay fed to stock cattle during the Winter, will not bring more than five dollars a tun. Of course the *raising* of cattle can only be made profitable, in districts remote from large markets, where grass and hay are very cheap. The grazing farmer relies entirely upon purchased cattle for his stock. He buys in the Spring, about the time grass starts or a little earlier, western cattle, generally grade Short Horns, three or four years old, already in good condition, or second rate beef cattle. Sometimes stall-fed animals are purchased, when the market is over-stocked, and they can be got low enough. If the season is too early for grass, they are put upon the farm and fed with good hay until the grass starts, though this is an exception to the general practice. The cattle are divided into herds adapted to the size of the pastures and have no change until they are ripe for the butcher. It is found that a change even from good feed to better affects the cattle unfavorably, often scouring them and hindering their thrift. They are occasionally salted, and with this exception have no care from the owner. They are brought into the highest condition upon nothing but grass. Some of the best beef sold in our market is made in this way. The meat has a mottled appearance, little specks and streaks of fat, running through the whole mass of lean. Sales are made from the herds at any time during the latter part of the season when prices suit. The cattle are taken from the pastures early in October to give the grass a chance to make a thick mat to cover the ground during the Winter. We recently visited a farm where this system had been pursued for nearly twenty years. The results were satisfactory both in regard to the pocket of the owner, and to the improvement of the land. He has a thorough knowledge of cattle, and watches the market closely, and his profits are of course somewhat increased by his skill in making purchases and sales. He buys in Albany or New-York, as suits his interest, generally for 7 to 8 cents per lb., net weight, according to quality. He has a standing offer for his cattle of ten cents a pound, the butcher taking them when it suits his convenience. It is found that the bullocks gain, in a season of six months, from two to four hundred pounds, in rare cases five hundred. If a bullock weigh twelve hundred dressed, he gets an advance of say two cents a pound on the purchase price, equal to about nineteen dollars, and a gain in the weight of the animal of say two hundred and fifty pounds, worth twenty-five dollars. This would be an advance of forty-four dollars upon the largest sized bullocks. The farm has carried a hundred head of these cattle, and some of the best pastures feed a bullock to the acre, but allowing two acres to the bullock, it would give a net gain of twenty-two dollars to the acre, which must be considered pretty good farming for this country.

The first impression is, that such pastures could have been made only by abundant manuring and thorough tillage, and that they must run down under such cropping. But we were informed that the yield of these pastures is more than double the yield of thirty years ago, under the common system of manuring and cropping. We could well believe it, for where a large herd had been feeding all Summer, there was a thick mat of herdsgrass, red top, and white clover that would have yielded over a tun to the acre. We never saw finer pastures. The only manuring practised, beside the droppings of the cattle, is an annual dressing of plaster, about two bushels to the acre. This keeps the land constantly improving.

It will be seen that this system of grazing fat cattle has some advantages over that of grazing young cattle and cows, as it returns to the land nearly everything that it produces. In raising young animals, all the bones and carcass are raised out of the soil and sold off. The four year old bullock has his bones already made, and his flesh in good condition. He only draws upon the land for a little more bone earth, and the mineral constituents of two or three hundred pounds of beef. Whatever the philosophy of the fact, the result can not be doubted, viz., a constantly improving soil, under this system.

It makes a very easy and genteel kind of farming, giving a fair return for capital, and affording a good deal of leisure to the owner. The hard work of haying and tillage is avoided in Summer and the care of cattle in Winter. Very little labor also is required. No tillage is required except for crops consumed in the family.

The great draw back to it is, that it requires a much larger capital than most farmers have at command. The fatting cattle upon this farm did not cost less than six thousand dollars. Several thousand dollars must be handled every Spring and Fall in order to carry on a grazing farm to advantage. It presents an inviting field of labor for gentlemen of large capital, who enjoy country life, but who do not quite relish the hard work, close confinement, and careful attention usually demanded by a varied husbandry.

Preparing for the Sugar Crop.

Thousands of acres of Chinese Sugar Cane are now growing in Ohio, Illinois, Indiana, Iowa, Kansas, and even in California, to say nothing of the large tracts planted in many of the other States. As far as heard from, with very few exceptions, the cane is maturing well, often remarkably so, and ripening heads indicate that the season of manufacture is at hand. For several years people planted more as an experiment than for profit, and in many cases the cane was suffered to waste for want of suitable implements to grind and evaporate the juice. The low price of Southern and West India sweets was not favorable to the profitable growing of the northern cane, with the limited knowledge then possessed. The case is far different now. Sugars are high, and the results of the past few years' experiments have proven that not only syrup of good quality, but well grained sugar can be manufactured from the northern cane at a profit, even were prices much lower than at present. Much, very much is due to improved implements or mills for grinding, and especially for evaporators which will rapidly convert the juice into a thick syrup for granulating. Conspicuous among them, and apparently quite in advance of others, is Cook's Rocker Evaporator, with which many tuns of *sugar* were made last season, and hundreds of tuns will doubtless be turned out this Fall. The manufacturers say Ohio is good for 6,000,000 gallons of syrup, and they are turning out 100 evaporators per week.

But what we wish to urge now is that suitable provision be at once made for promptly working up the coming crop. Too much reliance should not be put upon neighborhood mills, and evaporators, convenient and economical as they are, for with the vast amount of cane to be disposed of, some will doubtless spoil before it is reached in rotation. Every person who expects to raise a few acres of cane each year, needs a good iron mill and a medium size evaporator, and he should not leave the procuring of them until wanted for use, as there will doubtless be a scarcity the present season, so great is the demand. A poorly made, light mill is little better than nothing—often worse. When the cane was first introduced, *hand mills* were to do the crushing, but with two strong men at the cranks it was found that but a small portion of the juice was extracted. Next wooden rollers and light iron mills were tried, only to break down in the midst of the work. A strong three roller mill, worked by at least two horses, is needed where much grinding is to be done, the feeding rollers being 4 inch apart, while the final pressure is given by rollers which run directly upon each other, the whole keyed up very strong.

If the cane can not be used up before heavy frosts, let it be cut and either stacked in the field, covering with straw, or packed away in a shed or barn to be worked up as soon as practicable. It is better to strip off the leaves before grinding, which may be done with the hand after cutting, or by striking them from the cane with a forked stick, while standing. Save the ripest heads for seed, and remove at least 2 feet of the upper end of the stalk as worthless.

The juice should be rapidly evaporated as soon as it is expressed, using some kind of a shallow pan so as to expose as much surface as possible both to the fire and air. Cook's Evaporator alluded to above is admirably calculated to effect this. To granulate, set the thick syrup in shallow vats or other vessels, in a moderately warm place, and stir occasionally. After it has grained put in barrels or hogsheads with holes in the lower end to drain off the molasses or syrup. Of course everything connected with the grinding and boiling should be done in a cleanly manner. Nothing is needed to clarify the syrup, if it is rapidly concentrated and the scum faithfully removed, nor will such syrup need going through the refining process of the sugar house to fit it for market.

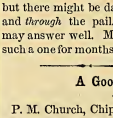
About Milking Stools—A New One.

Milking stools are dangerous articles in some barn-yards:—not in themselves, but as weapons in the hands of passionate men or boys, with which to belabor the frightened cows. This may have caused their banishment from many premises, as we have frequently seen milkers at their work on their bended knees or "sitting standing" as if doing penance for their want of patience. Instead, however, of dispensing with the bench, we would banish the milker who misused it by lifting it against the animal.

Some time since we received from J. E. Cutler, Essex Co., N. J., a drawing and description of what he claims as an improved milking stool. It is shown so plainly in the illustration that little description is needed. It is simply a bench long and wide enough for an opening in one end to hold the pail while milking, and afford a comfortable seat for the milker. The idea appears to be a good one, where the cows are all gentle, as they should be. But what if she give a sudden kick, as impulsive animals sometimes will? The pail could not well be overturned, but there might be danger of her stepping into and *through* the pail. With this exception it may answer well. Mr. Cutler says he has used such a one for months, and finds it just the thing.

A Good Bow-Pin.

P. M. Church, Chippewa Co., Mich., sends to the *American Agriculturist* a description of the simple and effective bow-pin, shown in the cut. It is made of half-inch round iron, with one end bent, to drop into a half inch hole in the top of the yoke, and the other made slightly tapering for easy insertion through the bow. The head of the pin resting in the yoke prevents all danger of its slipping from the bow.



Heading Late Cabbages.

It sometimes happens, either through the lateness of the season, or neglect in early planting, that cabbages do not head completely before cold weather sets in. These are often fed out to cattle, or thrown away, while by a little care they might be made to head during the Fall and early Winter. To accomplish this, proceed as follows: first, make a wide trench, and transplant the cabbages into it, setting them together in a triple row. At each end of the row, drive in a crotched stake, and lay a rail from one to the other, to form a ridge pole a foot or more above the cabbages. Make a roof of old boards or slabs, one end resting on the pole, and the other on the ground, so as to shed water. Over this, lay a little straw, six or more inches thick, and when Winter sets in, put on as many inches of earth, making the surface smooth and hard, so as to be nearly rain-proof. At each end of the row, leave a ventilating hole, which must be loosely filled with straw in cold weather. Cabbages so managed, will continue to grow, and will fill up their heads considerably before mid-winter. When taken out in Spring, they will be tender, crisp, and beautifully blanched.

Good Corn for Next Year.

Something may be done this month toward securing a good corn crop next year. First, as to the seed. It is established beyond doubt that the largest and best formed ears will be most likely to yield good successors. Before commencing to husk the crop, go through the field with a bag or basket, and pick the best, giving preference to the stalks yielding two or more good ears. If this be done before the whole crop is ripened, all the better, as the earliest can then be selected. By attending to this latter point a few years, the period of ripening for the whole crop, may be advanced several days, which in short seasons, might make a difference of many dollars in the net results.

Gather selected ears enough for your own use, and several bushels to sell to your less careful neighbors, who will next Spring be willing to pay an extra price for good seed corn.

Trace up the ears into bunches of convenient size, and hang them in a warm loft, secure from rats and mice, and where they may dry thoroughly before freezing weather. The vegetating power of corn is often destroyed by being frozen before the moisture is out of it. The water expands in freezing, and thus disorganizes the texture of the germ.

Then, as to the ground to be cultivated in corn next year: If it be heavy clay, or contain a large portion of that element, it will greatly aid next year's crop to plow it up this Fall, and leave it unharrowed. The lumps will be pulverized, insects will be destroyed, and if this be done early, the first crop of weeds and grass will spring up only to be cut down by the frost's keen scythe. We would advise spreading manure upon such lands before plowing. Being covered, it will not be wasted by washing away; the small part of its substance which may be dissolved, will be absorbed and held by the surrounding soil; mix it with the soil, and the speedy frosts will prevent loss by fermentation. Another important advantage gained will be the more thorough commingling of the manure with the soil, made by the cross-plowing next Spring. The more intimately this is done, the more certain will be the good effects of manure upon the growing crop.

In plowing undrained fields, arrange the lands with a view to carrying off surplus water. By a well planned series of dead furrows, the ground may be made ready for the Spring plowing several days earlier. Thorough underdraining is the best remedy for dropsical fields, but furrows are better than nothing.

How to Harvest Carrots.—Send a man with a sharp hoe through the rows, to cut off the tops. Then, beginning on one side of the patch with a plow, cut a deep furrow close to the first row of carrots; a second furrow will completely unearth them. Two boys with baskets will soon fill a wagon. When the crop is harvested, the land will be already fall-plowed.

Blinks from a Lantern....XXXI.

VISITS A WOMAN FARMER.

I never paid any particular attention to women when in the flesh. Perhaps that is a sufficient apology for my present interest in the "better half" of creation. My dwelling was rather too narrow for company, even if there were no more potent reasons for the cynic reputation that has survived me. To tell the plain truth, as a philosopher should, I always suspected it was the dweller, rather than the dwelling, that the women of my day objected to. It doubtless saved my feelings somewhat, to be told by this one, that my tub was too small for two; by that one, that my beard was too long; and by a third, that water would improve me. I took these not particularly complimentary hints, with the coolness of a philosopher, and remained wedded to my tub. I had occasion to observe, as I examined them by the light of my lantern, that the first had not even a tub at home, the second wore a wig, and the third wore more dirt than I did—with only this difference, that mine was a natural color, while hers was a tinge of red.

"A woman farmer!" exclaims a fair reader with lily hands. "The world has outgrown that idea." And possibly will have to grow back into it again. The only patent of a man's capacity for a given sphere of toil, is the fact that he fills it, and tried by this standard, as we have seen by the light of the lantern, there are not many men farmers.

"Just what do you mean by a farmer?" asks Mr. Higgings, with that solemn air which he puts on in his philosophic moods. Well, not necessarily a dirt-begrimed biped, with brawny arms, and a pair of palms like the hide of a rhinoceros. Such are to be found in large numbers upon the plantations of the South, clad in the coarsest material, and inured to the hardest work the year round, chopping wood, rolling logs, ditching, plowing, hoeing, and harvesting. Sex excuses no work. But it is not necessary that man, or woman, should do any of these things to make a first rate farmer. It is not necessary that a mason should mix his own mortar, or shoulder the hod. A man may be an architect without planing the boards, framing the timber, or driving the nails, or attending to any one of the details of building. A general need not fire cannon, or thrust with the sword and bayonet, and yet he may be well versed in the art of war. Strong limbs and tough muscles do not constitute a farmer. We have enough of these on most American farms, very good in their place, but no better than the brute sinews that drive the mowers and reapers, the rakes and drills, the cultivators, and hoes, that are doing so much to relieve human muscles, or dispensing with them altogether. The essential thing about farming lies in the *brain*, a region the blinks from my lantern fail to illumine, which perhaps accounts for my poor success in searching for a farmer. This brain I imagine is pretty much the same thing in man and woman. Philosophers of old were not agreed as to the question of sex in souls, and they are not yet harmonized. Whatever difference of opinion may exist upon this point, there can be very little as to the capacity of a woman to grasp the business details of a farm. It is no more difficult than many things which she does manage with aptness and entire success.

It is certainly as clever a thing to fit out a woman's wardrobe, especially if it be a fashionable one, as to stock a farm. She does this to a charm. She keeps a variety store, manages a bakery; sets type, binds books, writes and reads them, sings, paints, and makes herself immortal by the chisel. Why should not such a capable being *manage* a farm?

Mrs. Grundy has done it, and thus answered the question for her sex. She is a near neighbor of my friend Higgins, who has figured somewhat in these papers. Higgins poked fun at the idea of her farming, when she commenced, said he should as soon think of setting a woman to sail one of his ships. But he has experienced other emotions since, as she has frequently beaten him at the fairs, and last year got the prize for the premium farm in the county where Higgins was himself a competitor. To do my neighbor justice, he acquiesced in the correctness of the award.

She had some advantages which all women have not, but these were not such as take away from the substantial merit of her success. She was left a widow with six children at the age of thirty, upon a snug dairy farm, well stocked, but not more than half paid for. She might sell, she might lease the farm, or, manage it herself. She chose the latter, and people well acquainted with the parties say that she has managed with even more shrewdness and good sense than Mr. Grundy, who was a very fair farmer according to the popular estimate. She had to learn some things, of course. What sensible man does not, in every department of human effort, and still leaves many things unlearned. She is an excellent judge of horses and cattle, and would make a better decision at the shows than many put upon record. It would reform a woman-hater to hear her discuss the fine points of her favorite carriage horse, and the performances of her grade Devons and Ayrshires. It is womanly to paint horses and cows, why not to own them, and to manage them for pleasure and profit? If the inquiry is not hypercynical, is not a well dressed woman as attractive in a green meadow, admiring the liquid eyes of her grazing heifer, her sleek skin and swollen udders, as in a picture gallery, admiring the same things upon canvass? A woman's perceptions of form and color are, upon the average, as good as those of a man. Why should they not have their training upon wool on the sheep's back, as well as upon worsted work in the parlor? Mrs. Grundy was never able to discover why, and she knows a Saxony from a South-down, and is not ashamed of her knowledge. In the ornamenting of the homestead, she has greatly improved upon her husband's management. The bushes have disappeared from the fences, trees are planted by the road side, and by the carriage drive that leads to the house, which stands on an eminence a little back from the road. The dwelling and barn have the shelter of a belt of evergreens, which Mr. Grundy never thought of.

The result of her thirty years' farming, (for she is now an old lady), shows that she has understood accounts, and kept them. The farm has been paid for, greatly improved, and adorned; the children have been educated, and respectably settled in life, as the result of her enterprise. She has not held the plow, or driven, but has seen that work well done. She has understood men and women, and known how to use them wisely for her purposes. Mrs. Grundy is a woman of faculty, and for aught we can see, has as good a right to be a farmer as any man. With the example of this woman before him, the views of Higgins have undergone a change.

When to Sell Hay.

Most of our farms are in such need of manure that it is deemed bad husbandry to sell hay, and as a rule, it is only short sighted farmers that part with it at any price. If they can not pay for it in milk and beef sold, most farmers are certain it pays in making manure. With some it has passed into a proverb that "he that sells hay is a candidate for the poor-house." Unless something is restored to the land in the place of the hay, it is pretty certain to make a poor-house of the farm.

Here lies the whole secret of safety in selling this crop. The meadows must be kept in good heart, and if it is not done by hay consumed upon the farm it must be by some other process. Farmers living within a few hours of a good market and cheap sources of manure, can sell hay to advantage. The team that carries hay may bring back a load of manure. The farmer would really be at no expense for carting, for the cart would otherwise come home empty. If the manure were from a stable of grain-fed horses, the farm would be a gainer by the exchange. Cities and villages have many wastes that are cheap sources of fertility, and where these can be transported without much expense it will do to sell hay.

Then there are farms upon the sea-board and near sea ports, that may safely export hay. They have a cheap transit for their hay, and an inexhaustible source of manure in the fish and weeds which the sea produces. With a liberal use of these fertilizers a farm may be kept up to any degree of fertility. Farms without these advantages can rarely sell hay to a profit. The exceptions will be in the cases of farms liberally supplied with muck or peat, to form the base of composts, or those furnished with streams for irrigation. Muck, if decomposed with lime or ashes or fermented with any kind of animal manure, makes an excellent top-dressing for meadows, and with this, the soil may be made to yield maximum crops of hay.

It is asserted by men who have tried it for years, that meadows may be kept up to two or three tuns of hay to the acre by irrigation alone. In lands naturally or artificially underdrained, we have no doubt of the truth of this position. The productiveness of intervale land, where there is an annual overflow, confirms this position. Though artificial irrigation is little practiced in this country, the few examples that we have met with confirm the correctness of this position. We have little doubt that a brook, flowing through a farm of sufficient fall to be available for irrigation, is as valuable as a muck mine. The beauty of this mode of fertilizing is that after the dams are built, and the channels prepared, it costs nothing to keep the meadows fertile. You have only to look on and see the grass grow. We recently visited a farm cutting a hundred and fifty tuns of hay for this market, where water did the principal manuring. As the fields have gained in their annual yield for ten years, it may safely be inferred that they will yield grass abundantly as long as the water runs.

Shall we Cook Food for Animals?

Philosophically, the pro and con of this question seem about equally balanced; but practically, when done upon a large scale with the best conveniences, cooking food for fattening stock seems to have gained the ascendancy.

The philosophical arguments against feeding cooked food to animals are, in effect, that their digestive functions are naturally adapted to uncooked food, and that which is cooked anticipates some of the required processes of digestion, (passing into the stomach without sufficient insalivation and not inducing a sufficient influx of gastric juices, being among the evils) thus unbalancing the powers and deranging the functions of digestion. On the other hand, it is contended that cooked food requires less saliva and gastric juice, and hence saves an important draft upon the system. The results of experiments thus far seem to sustain the latter proposition. Of course it is not desirable to gain $20 worth of meat at the expense of $15 worth of labor and $5 worth of fuel, but if, in a larger field of operations, the proportionate cost of labor and fuel required for cooking be decreased, while the proportionate gain in value of meat remains the same, cooking will pay.

A correspondent of the London Gardeners' Chronicle, gives his experience and system as follows: "I have for 15 years fatted 20 to 24 bullocks, and 24 pigs, in boxes. My plan of feeding has been to give a morning feed, comprising about 30 lbs. of turnips sliced as thinly as possible, until I got pulping introduced, and then pulped, and very thoroughly mixed with chaff* as much as the animals would eat up clean. At mid-day the allowance of cake, commencing with 2 lbs. per head, and gradually increased up to 6 lbs. per head, has been made into a soup with water by steam, and poured, while boiling, over chaff in a slate cistern, layer by layer, until this was well mixed and filled; when full, it contains a feed for 24 bullocks. After this has been covered down an hour, the soup has been absorbed, and the chaff has become soft and mellow, and, as I believe, saves the animal the exertion of secreting an extra quantity of saliva to bring about the same result. The morning feed of pulped roots and chaff is repeated in the evening. I have adhered to this system because I have had every reason to be satisfied with the results. I have fattened upwards of 300 bullocks, and never lost one from first to last; they have enjoyed, I may almost say, invariable health, for veterinary attendance and medicine occasionally, would not amount to 6d. per head during the period I have mentioned. As respects quality, I perhaps need only say that the same butchers, from a distance, make their appearance at the farm buildings, about the same time every Spring, from whom I have never heard any complaint of meat shrinking either in the pot or on the spit.

The pigs have been fattened on carrots, steamed, with an addition of meal after the first month, gradually increased from 2 lbs. to 6 lbs. per head. The apparatus we use is Nicholson's (now Amies & Barford), consisting of a boiler in the center, a galvanized iron vessel on the left hand side in which the roots are steamed, and another on the right hand side in which the cake is converted into soup, and which is contiguous to the slate tank. Adverting to Mr. Frere's proposition in reference to extra cost of attendance and fuel, the case practically stands thus in our case: The attendance of one man and a boy would be necessary to prepare the roots, incorporate them with the chaff, feed, litter, and clean the stock of pigs and bullocks, whether the food was cooked or not. They perform the entire work, the chaff only being prepared for them. The cooking amounts to little more than lighting the fire in the steaming apparatus. Then as to the cost of fuel, we find the expenditure to average 5 lbs. of coal per diem, or from $12 to $15 per annum for 46 animals."

This writer also says that damaged straw and hay are rendered sweet and as valuable as any, by the boiling process necessary to the soup, and furthermore that the mustard seed so invariably found in rape-cake, rendering it highly objectionable, is deprived of its injurious qualities by the same heating process.

* "Chaff" in England means cut straw or hay.

Experiments in Feeding Stock.

The Highland Agricultural Society of Scotland, after trying a series of experiments with the view of ascertaining the cheapest cattle food, published the results in their Journal, as follows: Six bullocks, bred upon the Society's farm, and similar in appearance and aptness to fatten, were divided into three lots of two each. They were fed for 112 days upon Swedish turnips for the first month, turnips and mangel beets the second, and subsequently mangels. Each bullock had in addition, 6 lbs. low meadow hay, cut into chaff, and 5 lbs. oil cake, or its equivalent cost in other materials daily. The result showed that lot No. 1, fed on 5 lbs. oil cake each day per bullock, together with the chaff and roots, gained 637 lbs. during the 112 days. Lot No. 2, fed on the roots and chaff, with wheat and barley meal, costing same as the oil cake, gained 669 lbs. Lot No. 3, fed as above, substituting bruised linseed for the oil cake, gained 718 lbs., showing that the linseed was the most valuable, and the oil cake the least so. Again, the average increase in weight for the 112 days, was 337 lbs., and taking the cost of chaff, oil cake, and attendance, into consideration, it was found that the 90 cwt. of roots consumed, realized 49s. 6d., or 11s. ($2.75) per ton. This is quite different from Alderman Mechi's opinion of roots, in his crude book, "How to Farm Profitably," in which he says that the profits of twenty acres of roots all went into the manure heaps of the "ungrateful bullocks."

Keep to the Left!—Meeting Teams.

Can any body give a reason for the custom prevalent in this country, of requiring carriages and other vehicles to "keep to the right" when meeting each other on the highway? We noticed that in England, "keep to the left" is the rule, and a very proper custom it is, for this reason: The driver, if he carry and use a whip, must necessarily sit upon the right side of the vehicle, if any one sit with him. If now when passing another team, he keep to the *left*, he can readily see how much he must turn out to avoid clashing of wheels. The same is the case with the driver whom he meets. If on the contrary, they both take the "right" in meeting, they can neither of them see the wheels coming nearest together. They must therefore both turn out further than actually needed, or run the risk of clashing. A few inches, more or less, in a narrow road, or in a crowded city street, is often of much importance. A moment's thought will convince any one that "keeping to the left" is much the better way. In some States, there are laws requiring teams upon the road to take the right. In others custom regulates the matter. The reason we have given above is sufficiently important to warrant a change in the custom, and in the laws where they exist. The *American Agriculturist* proposes that the change be inaugurated without delay. It may seem odd, or left handed, but that is all a mere fancy, while many a clash and crash, and much inconvenience would be avoided by the proposed change.

Pulling at the Halter.

To cure this bad habit, some recommend hitching a rope to the horse's tail or hind leg, then to tie him to a post, in such a way that, when he pulls he will be thrown down, or at least be made very uncomfortable. A subscriber prefers this: "First, get an extra strong halter, and hitch him to an outer limb of an apple tree. Now, gently tease him, and provoke him to pull. The branch will yield, but still hold him fast. Tease him again and again, until he finds that he can not break his halter or effect any thing but his own discomfort. Repeat weekly until the lesson is thoroughly learned, and he will at length cease to pull when tied to a post."

Breaking Colts.

There has been great progress in this respect within a few years, owing mainly to a better understanding of the nature of the horse. It is now generally conceded that he can appreciate kindness and consideration, and that harsh and brutal treatment render him, (as well as children,) retaliatory, and disobedient when not under fear of the whip; and all colt-breakers should ever bear this in mind. The opposite extreme of laxness in discipline should also be guarded against. A person, to be capable of managing either a horse or a child, must be firm and persevering, but not harsh and revengeful. He must first conquer and control the animal part of his *own* nature, before he is capable of properly breaking a colt. Great patience and perseverance are required to quiet his natural fears, and satisfy him that you intend him no harm. All movements about him should be moderate and judicious. The hand should first be gradually brought in contact with his nose, as should every thing else new to him, because his nose is his instrument for testing whatever is harmless. What wonder that when suddenly seized or pounced upon, he exerts himself to get away? How can he know that the halter is not a contrivance to take his life? What need is there of giving him such a terrible fright, causing, as it often does, a trembling in every limb? Besides the inhumanity of such treatment, there is great danger that he will injure himself, or break away, and thus be encouraged in future attempts to free himself from restraint.

Anything that the horse can touch with his nose without being harmed, he does not fear. Therefore the hand, the halter, girth, blanket, saddle, harness, umbrella, buffalo robe, or whatever is to be brought in close proximity to him, should first be "introduced" to, and touched by that sensitive organ. A knowledge of these important facts, as we learned by attending a course of his lectures, is the main secret of Rarey's success in horse-taming. His strap method of throwing horses is useful only in cases of aggravated ill-temper, and such cases are usually, the result of mismanagement.

Cases are few in which colts may not be speedily and effectually broken by following the

directions, plainly implied by the above facts. Some colts, however, owing probably to some previous fright, will not readily allow persons to ride them. We have heard it recommended to make a man of straw, introduce it to the colt when haltered, gradually place it upon his back, fasten it *securely*, so that it can not be dismounted; afterward turn him loose and let him satisfy himself that it can not be got off, and that it will not hurt him. Thus the danger of any person being injured will be averted, and the colt will be effectually discouraged from making future attempts to throw his rider. Those who would have their colts long-lived, and serviceable in old age, should never work them hard when young. Allen truly remarks that "a due regard to humanity and sound judgment, in thus limiting the burden in his early years, would save much disease and suffering to the animal, and profit to the owner, by his unimpaired strength and prolonged life. The loss from neglecting this is enormous."

Harness for Oxen.

A subscriber agrees with us that "to make oxen draw by the neck is a refined sort of cruelty," but objects to our assertion that the true way for neat cattle to draw, is by the head. He says: "Although I admit that the 'power of the muscle is concentrated at the forehead,' (does not this settle the question? Ed.) still the strength of the neck and forehead do not warrant us in expecting so much of them. They were designed for other uses, not for us to contemplate now. The forehead has not breadth enough to allow it to be used satisfactorily. The draught would have a tendeucy, as the neck is so flexible, to draw the nose of the animal upward. If, however, the animal knows enough to obviate this difficulty by throwing his head downward, this would be an unpleasant position to work in. He has at all times to keep his head so that the line of draught will be at that angle where ox and weight are upon a level; it is this tendency in a yoke (of getting the neck and head down), that help to make the beasts pant and blow on a hot day, at the rate they do.

If you now place a leather collar upon his shoulders, and let it fit nicely, you will at once see an improvement. He will carry his head up to a corresponding hight, where he can get plenty of fresh air, and prevent it interfering with his legs. His head is free to balance himself, and swing to the motion of his body. With this collar you would, of course, need traces and breeching for road work."

No doubt a properly made collar and harness would be a great improvement over the yoke now used. Experience, after all, must decide the point. Have any of our readers thoroughly tested the three methods?

For the American Agriculturist.

Making Pigs Pay their Board.

My plan is as follows: Immediately under the edge of the floor, which is tight, I have a pit five feet deep, and extending in width and length 14x20 feet, into which is cast all the soiled bedding, refused food, and sweepings of the pen. As soon as this material forms a stratum of a few inches, I have it covered with soil or muck to the depth of six inches. This will soon become saturated, and I then repeat the dose. Into this I also throw all the coal ashes, old shoes, dead rats, offal of beeves, chamber slops, etc. A little care of this kind removes nuisance, and muck or soil secures the ammonia. From a pen in which were fattened nine nice porkers, I secured 73 well-rounded cart loads of manure. I think the manure amply paid me for the trouble, besides the satisfaction of having my hogs clean and fat. FARMER.

J. C. Taylor's Sale and Letting of South-Down Sheep.

This noteworthy event of the past month occurred at Holmdel, N. J., on Sept. 3. There was a large gatheriug of persons, including not only new breeders and purchasers, but those who, like Messrs. Thorne, L. G. Morris, A. B. Allen, and others, have loug been interested in introducing improved sheep into our country. We are are happy to report that notwithstanding the hight of the war excitement, and the general depression of the times, the sale was very satisfactory. The prices obtained were not up to those usually paid in England for the sheep of the same blood and intrinsic value, nor such as would probably prevail here in times of peace, and with a more general knowledge of the value of this breed of sheep. Still, as a glance at the figures appended will show, Mr. Taylor and others have not been on a "wild goose chase" when they have gone to the old world and at large expense procured the best blood that could be found. It will be seen, for example, that half a dozen ewe lambs, dropped this year, averaged nearly $35 each, and that of twenty such lambs, even the smallest brought $14, while others went at $20 to $41 apiece. After the first outlay in obtaining the pure blood, it costs less per head to grow these lambs than those worth only $3 or $3 each. Those prices were paid by intelligent men, looking to the profitable investment of their money. It is true that the prices were governed by the demand for breeding, but butchers would have readily paid twice as much for the same animals as they would have done for the common sheep and lambs of the same age. Any farmer accessible to a good meat market, and having 50 or more breeding ewes of any kind, can readily afford to pay $30 to $50 or more for the use of a South-Down ram. The increased value of his half-blood lambs would more than repay the cost. As soon as our markets get a little familiar with such South-Down mutton as we had the pleasure of eating daily while in England the past Summer, we are sure that there will be an almost unlimited demand for such sheep.

Of the value of the South-Downs, and of Mr. Taylor's flock, our associate wrote particularly, in the *American Agriculturist* for August (p. 233). We were glad to find at the sale, men from different parts of the country. The list of purchasers below will show that the forty nine sheep disposed of are pretty widely scattered—12 have gone to Pennsylvania; 11 to New-York; 9 to Illinois; 8 to Ohio; 5 to New-Jersey; 2 to Canada East; 1 to Connecticut; 1 to Massachusetts. They will each be centers of distribution.

The "Letting" or renting of rams for a season's use, to the highest bidder, though much practised abroad, is almost a new feature here, but will doubtless grow into general favor. The skillful professional breeder can keep on hand and best care for the pure bloods, and let them out for a month or two, to those who desire grade lambs, but who do not wish to go to the expense or trouble of keeping a single pure blood throughout the year. If we remember rightly, Jonas Webb, when in the business, let out about 70 rams annually, at prices ranging from $35 to $200 per annum, the average being between $100 and $125. (In one case he obtained 197 guineas, or fully $1000 for the use of a ram a single season). At Mr. Taylor's auction, the preference appeared to be to purchase, and at first only very moderate bids were made for the use of those rams which Mr. Taylor could spare temporarily, but which he did not, on account of their value, wish to sell at any price. Two were rented at $80 and $100, however.

RAMS RENTED FOR THE SEASON.

TWO-YEAR OLDS.

No. 106, "Webb's Favorite Yearling," imported in '61; To Hon. A. B. Conger, Haverstraw, Rock'd Co., N. Y. $52.50
No. 14, "Young Prize,"—sire, "World's Prize,"—dam, No. 71, imported in 1859, from Mr. W. Webb's Dishley Flock; To Harry Ingersoll, U. S. N., Philadelphia.. $25.00

SHEARLINGS (*One-year olds.*)

No. 24, "Young Partcranger"—sire, "Reserve,"—dam, No. 71, as above; To Peter Lorillard, Esq., N. Y. $100.00
No. 21, "Young Norwich,"—sire, "Reserve,"—dam, No. 4, imported in 1859; To A. C. Sissons, Esq., Waverly, Luzerne Co., Penn.. $80.00

SALES.

RAMS—SHEARLINGS (*Or one-year olds.*)

No. 1, Sire, "Vigor,"—dam by "Young York"; To Lawrence Hasbrouck, Esq., Kingston, Ulster Co., N. Y. $45.00
No. 5, sire, "Young Prize," dam by "Young York"; To Lawrence Hasbrouck, Esq.. $45.00
No. 8, sire, "Young Prize,"—dam, imported in 1859; To Geo. Batchelder, Esq., Stanstead, Canada East.. $52 50
No. 10, sire, "Reserve,"—dam by "Young York"; To T. B. Davis, Esq., Westchester, Chester Co., Penn.. $42.50
No. 12, sire, "Reserve,"—dam by "World's Prize"; To Hon. A. B. Conger, Haverstraw, N. Y. $47.50
No. 13, sire, "Reserve."—dam by No. 14, imported in 1859; To Judge N. L. Chaffee, Jefferson, Ohio.. $80.00
No. 15, sire, "Reserve,"—dam by No. 29, imported in 1859; To Wm. Black, Esq., West La Fayette, Ohio.. $50.00
No. 17, sire, Twin to No. 15; To J. T. Thorne, Esq., Chester Co., Penn. $35.00
No. 23, sire, "Reserve,"—dam by "World's Prize"; To Henry Pyle, Esq., E. Fairfield, Columbiana Co., O.. $40.00
No. 25, sire, "Reserve,"—dam by "Master Fordham"; To Lewis Hoops, Esq., Westchester, Penn.. $52.00
No. 26, sire, "Reserve,"—dam "Model Ewe," by Frank Forrest—dam, by Young York—g. g. dam, No. 6 at Col. Morris' sale; To Phineas E. Close, Esq., Greenwich, Fairfield Co., Conn.—(cheapest sale of day).. $61 00
Average. $51.86

EWES—THREE YEARS OLD.

No. 27, sire, "World's Prize,"—dam imported by Col. Morris; To Harry Ingersoll, Philadelphia.. $40.00

EWES—TWO YEARS OLD.

No. 9, (sire and dam same as No. 27); To Judge Chaffee, Jefferson, Ashtabula Co., Ohio.. $87.50
No. 33, sire, "World's Prize,"—dam imported in 1859; To A. C. Sissons, Esq., Luzerne Co., Penn.. $32 50
No. 39, sire, "World's Prize,"—dam by "Young York"; To A. C. Sissons, Esq., Luzerne Co., Penn.. $42.50
No. 42, (sire and dam same as No. 39); To Judge Chaffee, Jefferson, Ashtabula Co., Ohio.. $35.00
Average. $46.87

EWES—ONE YEAR OLD.

No. 44, sire, "Vigor,"—dam by "Young York"; To A. C. Sissons, Esq., Luzerne Co., Penn. $32.00
No. 45, sire, "Vigor,"—dam by "Frank"; To A. C. Sissons, Esq. $40.00
No. 46, sire, "Young Prize,"—dam same as No. 27; To Judge Chaffee, Ohio. $65 00
No. 48, sire, "Reserve,"—dam by "Young York"; To J. T. Thomas, Esq., Chester Co., Penn. $87.50
No. 51, sire, "Reserve,"—dam imported in 1860; To Geo. Bashter, Canada East. $87.50
No. 55, sire, "Reserve,"—dam by "Frank"; To Harry Ingersoll, U. S. N., Philadelphia. $40.00
Average. $42.00

RAMS—LAMBS, (*5 to 6 months old.*)

No. 3, sired by No. 89, (the famous $1,200 ram bought at Mr. Webb's sale, 1861)—dam No. 3, by "World's Prize"; To Alonzo Norris, Esq., Spencer, N. Y.... $30.00
No. 21, sired by No. 89—dam (10) imported in 1860; To Sanford Howard, Esq., Boston, Mass. $25.00
Average. $27.50

EWE LAMBS, (*5 to 6 months old.*)

No. 66, sire, "Reserve,"—dam by "World's Prize"; To Hon. John Wentworth, Chicago, Ill. $30.00
No. 68, sire, "Webb's Favorite,"—dam by "World's Prize"; To Hon. A. B. Conger, N. Y. $35.00
No. 72, sire, "Webb's Favorite,"—dam bought at Col. Morris' sale; To Wm. Black, Esq., Ohio. $31.00
No. 75, sire, No. 89, as above,—dam by "World's Prize"; To Hon. A. B. Conger, N. Y. $41.00
No. 76, (sire and dam same as No. 75); To Hon. A. B. Conger, N. Y. $37.00
No. 81, sire, "Webb's Favorite,"—dam by "Frank"; To Wm. Black, Esq., Ohio. $32.00
Average. $34.83

RAM LAMBS (*5 to 6 months old, sired by No. 89—dams pure bred, of different pedigrees.*

No. 1, To Hon. A. B. Conger, Haverstraw, N. Y. $15 00
No. 4, To Hon. John Wentworth, Chicago, Ill. $27.00
No. 5, To J. J. Conover, Allentown, Monmouth Co., N. J. $27.00
No. 6, To Alonzo Norris, Esq., Spencer, Tioga Co., N. Y. $21.00
No. 7, To Rev. Garrett Schenck, Marlborough, N. J. $14.00
No. 9, To John S. Conover, Esq., Holmdel, N. J. $16.50
No. 10, To J. J. Conover, Esq., Allentown, N. J. $14.00
No. 11, To Isaac K. Demott, Esq., Clinton, N. J. $18.00
Average. $16.58.

8 EWE LAMBS, (Nos. 1, 2, 3, 4, 5, 6, 7, 8.)

(*Pedigrees same as the above.*)

All to Hon. John Wentworth, Chicago, Ill.: $26—$16—$16—$24—$21—$21—$21—$22 (averaging $20.87).... $167.00

Total of Sales and Lettings..... $1,584.50

[The above figures we prepared on the ground, and afterwards compared them with the auctioneer's books

THE FUCHSIA—*Engraved for the American Agriculturist.*

The increasing demand for house-plants that grow well without scientific care, and bloom profusely for a long period, has brought the Fuchsia, (often styled "Ladies' Ear-Drop,") into high favor. Among its several varieties are those which flower both in Winter and Summer. Chili, and the region of the Andes, have the honor of originating this class of plants. The first wild flower discovered was scarlet, but by patient hybridization, upward of one hundred varieties of other colors and shades and form, have been produced. The aim of the hybridizer is to reach a certain standard of excellence, which consists in having the sepals reflexed back to the stem or tube of the flower, and the corolla well expanded. In respect to colors, tastes differ. Some prefer white sepals and crimson or rose corollas; others, purple corollas and crimson sepals; others, white corollas and crimson sepals. Some have a special fancy for single flowers, others for double. The field of selection is large enough to suit every taste.

The number of *Winter-blooming* Fuchsias is not large. Perhaps the very best for this purpose, is the well-known *Speciosa*, with its rosy white sepals and crimson corolla. After this, may be named, *Hero*, *Serratifolia*, *Diademe de Flore*, *Snow-Drop*, and *Prince of Orange*.—To have them bloom well, pot them in large crocks, having good drainage, and filled with a porous soil composed of sand, leaf-mold, old rotted manure, and common earth, in equal quantities. For the best effect, they should be trained to a single stem two or three feet high, with the branches hanging from the upper part in graceful pendants. Keep the temperature between 60° and 70° by day, and not below 40° by night, supplying the roots with an abundance of water; keep the air of the room as moist as may be, and there will be no lack of blossoms. On the opening of Spring, set them out in some retired corner to rest, and to become vigorous for another Winter's work. About the first of September, re-pot them in soil such as we have before mentioned, cutting them back somewhat severely; keep them a week or two in the shade, and well watered until they have become re-established; then bring them into the house.

Summer blooming varieties are to be treated in a similar way, as to soil, pruning, etc. In Winter, keep them under the stage of a green-house, or in a dry cellar. It is a great mistake, not seldom practised, to set out the plants in Summer, in a sunny situation. To preserve the foliage fresh, and to maintain an abundant and long-continued bloom, they require a partially shaded aspect, such as the north side of a house, or a sheltered piazza, or the stage of a green-house, taking care to have the glass well covered with whiting, or darkened by awnings.

As to the best varieties, tastes will differ; but the following are undeniably good sorts: Prince Albert, Wonderful, Duchess of Lancaster, Florence Nightingale, Spectabilis, (this is styled by Dr. Lindley, "the Queen of Fuchsias,") Psyche, Princess Royal, Emperor Napoleon.

An amateur hands us the following: "For twelve first rate Fuchsias, take these: Ariel, Clio, King, Prince Arthur, having light colors with purple or red corollas; Alpha, Glory, Hendersonii, Omega, Perfection, President, Prince Albert—scarlet colors, with crimson, purple, or blue corollas; Queen Victoria, red, with white center or corolla. Give me these dozen varieties in my garden, and I care for none beside."

Propagating Grape Vines.

At this season of the year, many thoughts are directed to this subject, and many inquiries made of those who are supposed to understand it. A special interest has of late been awakened in it because of the superior excellence of the newer varieties, and of their profitableness for market. We will now describe several different methods, leaving the reader to choose between them.

LAYERING.

This is the surest, and in some respects the best. The common way is to bend down, early in the season, a cane of last year's growth, dig out a trench three inches deep, and as long as the cane, peg down the shoot by short pins, and cover it with earth. Spread a few leaves, or short grass, over the surface, to keep the ground moist. Roots will form all along the cane, and from the strongest buds shoots will spring up. In Autumn, the cane may be severed from the parent vine, and may be cut into as many parts as there are shoots with roots.

When it is desired to get as many new vines as possible, a *better* way is to let the cane lie on the top of the ground until early Summer, until shoots have pushed six or eight inches from every eye, then peg it down in a shallow trench, and cover it with soil. Roots will soon strike out at the base of every young shoot, and we shall be quite sure to get as many new vines as we have eyes. If the vine is old, and has been trained so high that canes cannot easily be layered, resort may be had to the following process. Take a large flower pot, draw a side grape shoot up through the hole at the bottom, fill the pot with sandy loam, and hang it to a stiff branch above, or to a hook on the frame. The cane should have the bark scarred near the base of a bud in the lower part of the pot. This will favor the emission of roots. Keep the ground moist by frequent waterings, and a new plant will soon be formed. Cut off the cane below the pot, in Autumn, and the work is done.

CUTTINGS.

These are of two sorts, the long cutting for planting in the open ground, and the short, for starting in hot-beds. The long cutting should contain two or three buds, the wood should be ripe and strong, and the buds plump. Taken off at the fall or winter pruning, they are easily preserved in a bank of earth out of doors, or in a cool part of the cellar. Each cutting should have a bud close to the base, and if there is a piece of the old, or last year's wood attached, it will be more sure to strike well.

In planting, choose soil of a sandy loam, not a stiff clay, and not wet. If it is very sandy, the cuttings will be apt to dry up in mid-summer. If the land is cold and stiff, work in a little sand, especially in the part occupied by the base of the cuttings.

Suppose we have a hundred or more cuttings: we will begin the work by spading up the ground, and putting it in the best condition. Level it down handsomely, draw a garden line across the patch on one side, and cut out a trench one foot deep. Set the cuttings in obliquely; if set perpendicular, the lower buds, being so far from the heat and air of the surface, will rot off without forming roots. The lower bud should not be deeper in the soil than six or eight inches. The upper bud should be just on the surface; if higher up in the air, the cane is apt to dry up. The cuttings being in place, fill up the trench and level off smooth. Proceed in the same way with other rows, until the cuttings are all planted, leaving a space of eighteen inches or two feet between the rows for convenient cultivation through the Summer. If the season is very dry, mulch between the rows.

SINGLE-EYE CUTTINGS.

These are employed chiefly in the propagation of choice varieties, where the vineyardist can not afford to use so much wood as is required in the long cutting, and where it is wished to make a little wood go a great way. These cuttings, or more properly buds, are prepared by taking a single one, with an inch of wood on each side of it, and splitting off nearly half of the wood underneath the bud. This last operation facilitates the striking. The buds are then set out in a gentle hot-bed, about half an inch deep, or in pots or boxes plunged in a hot-bed. The latter method is generally most successful. They should then be regularly watered and ventilated until the young vines are hardened off enough to be removed to the open air. Experienced propagators prefer this method to any other. It not only saves a great deal of wood, but, as each new plant retains only a trifle of the substance of the parent vine, it is almost as truly-a new vine in its constitution as one raised from seed. We only add that if these eyes start well, they will become fine little plants the first season. It is better, however, to set them out in nursery rows until the second year, before a final planting.

GRAFTING GRAPE VINES.

Another method sometimes used for propagating the vine is *grafting*. Old vines of an inferior sort *may* thus be made over new, in one or two seasons. Wild vines may be dug up from the roadsides and grafted in the Winter, and set out in the Spring. These soon make strong plants.

Protection of Young Trees in Winter.

So many are the losses every year from the effects of Winter, that this subject is worthy of special mention as the trying season approaches. A few words of precaution are needed now:

There are many considerations in favor of fall-planting. One has usually a better lot of trees to select from at the nurseries, than in the Spring. If set out early, the wounded roots become calloused, and ready to emit new roots in the Spring; they may even begin to form roots in the Fall. They are fairly in their new quarters at the very opening of Spring, and ready to start at the first beginning of warm weather. Fall planting saves much time for other work in Spring, which is always a busy season. In the Fall, the ground is warm, comparatively dry, and easy and pleasant to work.

It can not be doubted that the hardiest trees, such as apples and forest-trees, may be set out in Autumn to the best advantage. But those slightly tender—such as cherries, some kinds of pears and shade trees—if taken up in the Fall, should be "heeled in," and protected for the Winter. They will then be in the best possible condition for planting out in the Spring. And here is the way of doing it. On receiving the bundle of trees from the nursery, choose a dry and partially sheltered corner of the garden or orchard, lay open a trench about a foot deep, sloping it off on one side, and making a hillock on that side for the trunks and branches to rest on. It is taken for granted that this trench is made where no water will stand in it. Now lay the roots along in the trench as closely together as possible, the limbs resting on the bank of earth. Cover the roots a foot deep, making a mound over them to shed water. Let also the trunks be slightly covered, for full half their length. It is well to lay a few evergreen bows over the branches; cornstalks may be used, though in moderation, or they will attract mice. As soon as Spring opens, remove all covering, shorten in the branches, and plant.

For trees planted within a year or two past, a slight Winter protection is important, at least in exposed places at the north. The roots of such trees are yet small, and have not recovered from the shock of removal. The main thing required is to cover the entire body of roots with a few inches of extra soil. If coarse manure is at hand, use that, and it will answer the double purpose of protection and enrichment. In Spring, let the manure be worked into the soil. Wherever there is danger from mice, a conical bank of earth, about a foot high, should be made around the stem of every newly planted tree, removing it early in Spring.

A Paying Investment—Plant Trees.

For how much money would you cut down the fruit and shade trees on your farm? Every owner will, in reply, name a sum far above the cost of planting and raising them. This proves conclusively that tree planting will pay. We know of no more certain way to increase the market price and the salableness of a farm, than by stocking it with trees. The satisfaction to be derived from abundance of fruit and shade, the attractiveness thereby given to the *Home*, and its good influence upon the family circle, these can hardly be estimated in dollars and cents.

Now is the time to make this richly paying investment. Commence in the vicinity of the dwelling. The peaches, cherries, and other stone fruits, and tender trees, will be better left until next Spring. For apples, pears, and deciduous shade trees, the best time is when the frost has nearly stripped them of leaves. They become well settled in their places during Winter, and are ready to commence growth when Spring opens. A few essential points need attention in transplanting. Large trees *may* be successfully transplanted by using extra care, but it is generally far preferable to take those of only a few years' growth. In a few years they will outstrip those of larger size, and be of better shape, as they need little pruning when removed.

When taking them up, use great care not to injure the roots, particularly the smaller fibers; these draw most of the nourishment taken from the soil. All injured roots should be pared smooth; they will then heal more quickly. The better the soil is made *before* planting the trees, the more speedy and thrifty will be the growth. It is essential not only that a few feet immediately around the trunk be enriched, but that the whole area where the roots are to extend should be in good condition. If the location be wet, draining must be resorted to, or all other labor will be mostly wasted; the trees will drag out a short and profitless existence.

Make the holes large enough to allow of spreading the roots to their full length, and lay them all out in the direction of growth. Set the trees at the same depth as they originally grew.

If an orchard is to be set out, the following simple contrivance (republished from a former volume,) will enable a person to place them in exact rows. It is merely a strip of board, about eight feet long, with an opening from one side to the center, large enough to admit any tree to be planted, and having also a hole, say of an inch in diameter, near each end. It is used thus:

The ground having been staked out in the usual manner, the board is placed with the center opening over a stake. Now insert two small pins in the ground, through the openings in the end, and lift the board, leaving the pins in the earth. Next dig the hole, and when completed, replace the board over the end pins. The opening in the center shows the exact place the stake occupied, and the trunk of the tree being introduced through the side opening, will be held in the same place, while the hole is being filled, thus greatly facilitating the work.

In planting fruit trees near the house, avoid setting them near fences. Besides the temptation offered to climbers, and passers on the highway, much fruit will be lost by falling and being bruised upon the fence. Let such places be occupied by tall-growing deciduous shade trees, as the maple and elm. Evergreens may come next, then the fruits near the house, where they may be seen to best advantage by the occupants.

Pears in the Northwest.

Mr. C. D. Bragdon gives in the Rural New-Yorker, a lengthy pear talk from the orchard of R. Douglass, who has 1000 to 1400 trees, half of them in bearing, at Waukegan, Ill., on the shores of lake Michigan, 40 miles north of Chicago. By the way, this is in what is being designated as the "North-Western Fruit Belt," embracing northern Ohio and Indiana, southern Michigan and Illinois. Western New-York might also be included, and, in fact, the whole of the country bordering upon the great lakes, and lying between 41° and 42°, which takes in the southern peninsula of Canada West. The great pear-growing region of Boston and vicinity, on the Atlantic coast, is in the same latitude.

Returning to Northern Illinois, we find Waukegan bidding fair to rival Boston in pear culture. The soil varies from a stiff clay to a deep sandy gravel. Mr. D. speaks at length upon the different varieties, from which we extract the following: *Louise Bonne de Jersey*—nothing equal to it on the quince, upon which I would grow it altogether; bears heavily every year, and still grows well; have 30 to 40 trees in every variety of soil and situation. I would rather grow the *Bartlett* on pear than on quince, is not very hardy, but when *headed low*, it endures hard winters here very well. It brings the highest price in market, and is a pear everybody should grow, but will not thrive in very exposed situations. A dwarf Bartlett, ten years from the bud, was loaded down with fruit. *Vicar of Winkfield* succeeds poorly as standard or dwarf. It does not fruit, neither does the *Duchesse d'Angouleme*. The *Buffum* is a fair pear, a good grower, and productive, but does not come into bearing very young. *Belle de Bruxelles*, is a great bearer, fruit large and handsome, but worthless. *Rostiezer* is a good summer pear, and a fair bearer. *Belle Lucrative* is a good bearer on both pear and quince, and the trees are hardy. I think a great deal of the *Canandaigua*, on account of its upright growth and fine foliage. *Onondaga*, or *Swan's Orange*, does not prove quite first rate, but is a good bearer and hardy; it succeeds on both pear and quince, though liable to overbear on the latter. *Seckel* killed some during the hard winter, but will probably be a good tree here on both stocks. It is full of fruit. *Glout Morceau* is a good winter pear on quince; it comes late into bearing, but yields well; is hardy, and sells well, ripening in January and February. *Beurre Diel* is an uncertain bearer, not to be depended upon. *Doyenne d'Ete* is a good summer pear, very productive, and a regular bearer. *Tyson*, good on pear and quince, is rather late in coming into bearing, but promises well. I can not do the *Flemish Beauty* justice; "it bears early and often, and all the time" as a standard. There are hundreds of bushels growing about here. Every tree is loaded, and this variety is considered *the* standard pear for the West—hardy and always productive. The Flemish Beauty on pear, and Louise Bonne on quince, may be emphatically recommended, and a bushel of either sort can be raised as *soon*, as *easily*, and as *surely*, as a bushel of apples, anywhere that apples will grow. This has been demonstrated in a hundred localities, and can be relied on. Such is the experience of Mr. Douglass at the West. In regard to the sureness of the pear crop, Mr. Wm. S. Carpenter, a successful pear grower of Westchester Co., N. Y., who chanced to hear us read the proof of the above, remarked that he would rather raise a bushel of pears than apples, considering them a more certain as well as a more profitable fruit.

Pruning Trees at time of Transplanting.

Here is a mooted point, with something to be said on both sides. Certain theorists declare that a tree should *not* be pruned at the time of transplanting, because it needs the branches to elaborate material for new roots. The roots are weakened just in proportion as the top is diminished. Leave on the tops, it is said, until the roots are partly restored, then (say, the year after removal,) give the top a moderate pruning. That a tree closely pruned *looks* bad, no one will deny. On the other hand, it is replied, every newly dug tree has many of its roots cut off or mangled, and we must diminish the top in order to maintain the balance of parts: otherwise, the superabundant branches will pump the feeble roots dry. With care a tree may be transplanted, without pruning; but experience shows that one suitably shortened-in will recover from the shock of removal, and make a more vigorous growth in three years than one not pruned. If small trees are taken up with care, and immediately set out in the same garden, they may require little or no shortening-in. This is often done by nurserymen. But trees taken up in haste, and in the rough, bungling way often practised, and then exposed to sun and wind, one, two, or more days, can hardly be expected to live without vigorous pruning. Better prune at this time, and seldom use the knife afterward.

Upright Trees.

When crooked, lop-sided, leaning trees are seen in a wild forest, we call them picturesque, and let it go. But when we see them in a neighbor's orchard, (or our own), or by the roadside, or in a lawn, we say somebody is to blame, for generally it comes from sheer neglect. As to *leaning* trees, the history is something like this: when first transplanted from the nursery or the woods, they are straight and tall. They are set out in exposed places, and not being staked and tied up, they soon get out of the perpendicular. This is not to be wondered at, considering the smallness of the roots, and the softness of the soil. It is a very easy matter to prevent this. Let every newly planted tree be staked and tied up, using broad and soft bands to prevent chafing the bark. Or, in the lack of stakes and bands, use heaps of stones laid over the roots on the windy side, which will ballast them. In case a tree gets thrown over, it can be righted up by loosening the earth about the roots, and then drawing it up and fastening it to a stout stake. If it has stood leaning for several years, it may be necessary to use an ax on one or two obstinate roots. But by all means get every tree up straight and then keep it up.

A Talk on House Plants.

None can deny the pleasantness of house-plants in Winter. When the hills are clad with snow, and the cold winds howl about our windows, it is not the least promoter and token of comfort and home content, to see a fine stand of plants, blooming and green. They need not be of rare and costly varieties; the number need not be large; only let there be a collection suited to the circumstances of the household, let them be well kept, and the sight will please every eye. We have often noticed how even a single plant in a window redeemed the room from barrenness, gave it an air of comfort and refinement, and prepared us to think well of the occupants. It diffused a certain air of culture and taste through the apartment, a something purer and higher than could come from the most splendid display of rosewood and gilding. Yet it appears that of late years there are fewer *good* collections of house-plants than formerly. Why so? Because our modern houses are made so tight as to exclude nearly all fresh air; because we heat many of them with coal-stoves or furnaces, and light them with gas. Here, then, comes up the practical question of how to grow house-plants successfully?

1. A first requisite is a suitable degree of *moisture*. Who does not see, every year, fine plants at the kitchen window, and poor ones in the parlor? And this, because the evaporation of water from the cooking-stove or range, supplies the air with an abundance of moisture. Some plan, therefore, should be contrived for generating a healthy degree of moisture in our parlors and living-rooms. It is not impossible to do this. A house warmed by a furnace, should have a broad pan of water in the hot-air chamber, or an evaporator at the register of the room containing the plants. Pans of water may also be placed on the plant-stand, whose slow evaporation will be of some account. Rooms heated by coal or wood stoves, should have some vessel of water on them continually evaporating at least a quart or two of water daily.

Here is another method: nail a cleat on the outer edge of the plant-table, or the edges of the shelves, raised an inch or two higher than the surface of the table or shelf. Set on the pots in their saucers, then fill up the spaces between with moss, or sand covered with moss. The appearance of the moss will be ornamental. Moisten this moss and sand thoroughly, morning and evening, and this will diffuse a constant moisture among the leaves. The roots must, of course, be watered. No universal rule can be given for this, some plants needing much, and others only a little water. Those at rest require only just enough to keep them from wilting. Those in active growth and bloom need much more. For the majority of such plants, the simple demand is that the whole body of the earth be kept moist, not wet. See that the pots are well drained; then water may be poured in freely, and with little risk of harm. To find out when a plant needs watering, examine the soil with a sharp stick, or better still, by rapping the sides of the pot. If it gives out a hollow sound, the plant needs more water. Then give

it enough to saturate the whole mass of earth, and to run through into the saucer. Do not water again until necessary.

3. A suitable amount of *light* is needed. For the first half of the Winter, there is little danger of too much light; but after the month of January, the mid-day sun becomes a little too bright for some sorts of plants. This is the case especially with those in a half-dormant state. Drop the curtain at mid-day, or let these plants be kept in a somewhat retired part of the room. For others, an abundance of light is needful, if we would have well-formed and well-colored blooms, and healthy foliage. A south window is of course the best aspect, and next to this a southwest or southeast window. Turn the pots around once a week, or oftener, to prevent the plants becoming one-sided and drawn up.

3. The amount of *heat* should not be overlooked. As dwellings are now constructed and warmed, there is more danger of over-heating than the opposite. A few plants—those especially of tropical origin—require a high temperature, but the majority thrive best at a moderate heat. Those commouly kept in parlors require about 40° by night, and 60° to 65° by day. Much harm is often done by sudden fluctuations of temperature, caused by letting the fire go down at night, and by opening doors and windows when the air outside is too cold.

4. And this suggests the subject of *ventilation*. Frosty air should not be allowed to blow directly on the plants, yet they need fresh, pure air. In their anxiety to keep their plants warm, many persons confine them continually in air which has long been filled with the odors of vegetation, the gases from the stove or furnace, and the dust of the apartment. As often, at least, as once a day, the window or door of an adjoining room should be opened, and a current of pure—not cold—air, should be made to blow through and among the plants. Whenever the mercury is above the freezing point, a window in the room should be dropped from the top. It were well, also, if all the windows of the room be so loose at the joints as to allow fresh air to steal in continually, and thus give the plants constant refreshment.

These are the main neccssities of house-plants. It is a good thing to syringe them daily overhead with tepid water, or to wipe off the dust from the leaves with a sponge. Insects should be guarded against. Many can be killed by thumb and finger; indeed, we have known a large set of plants kept clean by five minutes daily manipulation. For those who don't like this, a decoctiou of tobacco leaves, or whale-oil soap, answers au excellent purpose. Stir the surface of the soil in the pots frequeutly, to prevent it becoming hard. Among the plants which succeed well in rooms, we name the following, for a small assortment: *scarlet geraniums, monthly roses, pelargoniums, African lily, fuchsias, monthly carnations, striped abutilon, petunias, ivy-leaved geranium.*

Winter Covering of Strawberry Beds.

All experience shows that in gardens at the north, strawberries are benefited by a little protection in Winter. The *alternations* of temperature do more harm than any amount of mere cold. In Maine, Canada and Vermont, where the snow often lies from Novcmber until April, there is less need of artificial protection than in N. Y., Penn., and Connecticut, where the snow comes and goes continually. In dry sandy soils, too, there is less harm from frost than in heavy, clayey lands; in the latter, the plants are often thrown out and killed by the freezing and thawing of a single Winter, or open Spring.

But what is the best material for such protection? The material with which nature covers her strawberry patches is leaves. And if one will use leaves, and then take the trouble to cover the leaves also, to keep the winds from blowing them away, nothiug can be better. We have used them, covering them with old peabrush and the canes of last years raspberries, etc.; but the winds of an open winter would blow them off from many a plant. We have used straw, but sometimes mice would burrow in it and nibble off the crowns of the plants. Coarse, littery manure does very well, but it brings in weeds, and so makes work for next Summer. Saw-dust answers a good purpose, but it often brings in grubs. Old tan-bark suits us about as well as anything. It is our practice to apply it late in the Fall, covering the leaves about one inch, and then removing a part of it in the Spring, leaving the rest for a mulch in Summer. We have used it now for six years, and find no serious fault with it. It is a perfect protection in Winter, harbors no vermin, brings in no weeds, but rather keeps them down. It is one of the best equalizers of temperature the year around, in Summer saving the necessity of artificial watering. As to its affording the plants a specific manure (tartaric acid,) as some assert, it is unnecessary to express any opinion.

Terraced Gardens.

That a hill-side garden has a fine appearance when thrown up into terraces, there can be no doubt This is owing, partly perhaps, to the appearance of art displayed in the work; partly to the emerald grassy slopes intervening regularly between the rows of bright flowers planted on them; and partly to the bold, conspicuous manner in which it throws up to view the forms of the plants, presenting the whole mass at one view, like plants on the stage of a large greenhouse. Whatever the reason, the fact is evident.

Whenever the hillside is so steep that it can not well be worked into natural, flowing slopes, we would recommend terraces. Yet they must be made with care, or frost and heavy rains will soon break them down. A long, straight line of terrace is much more likely to slide away than a flowing curved line. If such a straight terrace must be made, it is important to break it up, at convenient distances, into buttresses, which will give very much the same support that they do in a wall of stone. Furthermore: the upper and outer edge should not be made too sharp; for the frost and hot suns will be sure to destroy the grass upon it, leaving bare and crumbling patches of ground.

On such terraces we would recommend planting shrubs and other plants which stand up somewhat boldly above ground. Trailing plants, such as the verbena, portulacca, etc., would, of course, produce no marked effect. Shrubs and herbaceous plants should be intermingled, and so arranged that at least a portion of each should be in bloom all the season. Of shrubs, a good assortment would include the Japan quince, lilacs, spiræas, deutzias, syringas, upright honeysuckles, weigelias, altheas, euonymus and perpetual roses. For herbaceous plants we name Dielytra, Peonies, Monkshood, Canterbury Bell, herbaceous spiræas, Phloxes, Lilies, Dahlias, Scarlet Geraniums, Gladioli, etc. An occasional vine well fastened to a stake or ornamental pillar would have a fine effect.

The Pampas Grass.

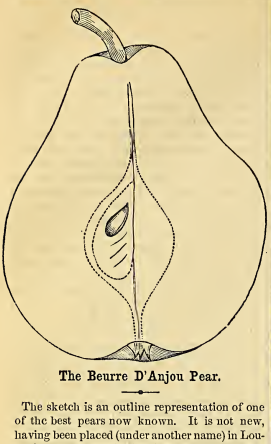
Among the novelties of the day, in the ornamental line, few things are more desirable than the Pampas Grass, (*Gynerium argenteum.*) It is a native of Brazil, and therefore requires some protection here, in Winter, though we understand that in England it endures the hardest frosts. No description that we can give will convey a just idea of it to those who have not seen it. It resembles the Tritoma, somewhat, though the leaves are much longer, and more rush-like. They often reach six and eight feet in length, bending over at the top as gracefully as a weeping willow. They are bluish or silvery green in color. But let us turn the description over to an enthusiastic cultivator: "It is a perfect fountain of green foliage and feathery flowers which, under a brilliant sun, appear spangled with silver..... It throws up from ten to forty stems, terminated with a panicle of light colored flowers." Another writes: "I have a Pampas Grass with over forty flower stems, ten to thirteen feet high. It might be described as a fountain of vegetation, acquiring more and more force from day to day, till at last the gushing fluid springs up into jets of living silver!"

Now, a plant which produces such jets of rhetoric must be worth looking after. We have seen it for several years, and watched its habits, and though it has not made such grand displays as the above would lead one to expect, it nevertheless has proved an interesting object. For the finest display, it should be set in the middle of an oval bed, and surrounded by other plants of similar foliage. Among these we may mention the several tritomas and the gladioli. The soil should be deep and rich. An occasional watering would promote the rapidity and luxuriance of its growth. In the Fall, as soon as the first frosts appear, it should be taken up and set out in a large pot or tub, and then removed to the cellar for the Winter. A retired corner of the green-house would answer better. South of Washington, this winter protection would be unnecessary, and there it would attain a perfection in size and luxuriant flowing which can not be expected at the North. Still, it is well worthy of all our care, even here.

Tree Mignonette.

This is nothing new. It is only the common annual plant, brought under the following treatment: Pot a single plant, and when it has attained a strong growth, trim off the side branches and tie up the central stem to a neat stake. As soon as the blossom buds break at the top, nip them off. The leaf-buds below will again push out, and may be allowed to grow three or four inches long. After a while, a few blooms may be suffered to form, but let them not go to seed. Follow up this practice perseveringly, and in a few months the soft, succulent stem will become woody and rough, like a shrub. It will then live for ten or fifteen years, and blossom nearly all the time.

THE "GREAT AUSTIN SHAKER SEEDLING" STRAWBERRY.—Continued inquiries, impel us to say again, that we can not recommend this variety for general cultivation, while there are so many others better. It is large and prolific, and late—the last named, its chief recommendation—but it is soft, does not bear carriage well, and has not the best flavor. It has strong advocates, but the above is the more general impression.



The Beurre D'Anjou Pear.

The sketch is an outline representation of one of the best pears now known. It is not new, having been placed (under another name) in Loudon's select list of 1834, but is of comparatively recent introduction here, under its new cognomen. It grows finely on the quince stock. The writer has fruited it during several years.

The tree is a moderate grower, of good form, the wood and leaves bright and healthy, and it never suffers from the hardest winters. The fruit is nearly as large as the Bartlett, though of different shape; in quality it is fully equal to that favorite variety, and of sweeter flavor. In the language of the fruit books, it is "large, long, oblong, obovate, pyriform, obtuse at stem; color, pale yellow, dull blush, and numerous small specks of faint russet; calyx open, segments thick, reflexed; basin round, not deep, russeted; stem short, curved, and obliquely inserted in a shallow cavity; core small; seeds long, pointed; flesh yellowish white, melting, juicy, vinous, sprightly, delicious to the core. Ripens in October and November." In those sections where the Easter Beurre does not mature well, and so make a good winter pear, this is a good substitute, though it is not quite so late. We often keep them into January. Gather in mid-October; pack in half bushel boxes, putting on a loose cover. They may be ripened up in November, though if kept in a dark, cold cellar, they will last till New-Year's.

How to Keep Apples.

Late last Spring we were enjoying apples picked and packed the previous October in Western New-York. They were as fresh and juicy as the day they were put in the barrels. The secret of their long keeping is worth knowing by all Eastern people who order their fruit from the West, and who have lost much by the bruising of the apples on their long journey. They were packed, when they were shipped, in oats, and have been kept in a close, upper room through the Winter. The advantages of this method are several. You get oats for about thirty per cent. less than the price in the eastern market. These are handy for the horse, if you keep one, and for the hens, if your stock is limited to a few fowls. They preserve the apples from all bruises on their passage, by rail or canal, which is impossible without something to fill up the crevices. As the freight is so much per barrel, there is no additional charge for the oats. The oats are a great safeguard against rotting, where the apples are kept in a close, tight room, without fire. The close room, and the still closer envelope of the barrel and the oats, guard against the sudden changes of temperature so common in our winter climate. With the thermometer at zero out of doors, they will not freeze. If they should be frosted a little, it is drawn out so gradually by the oats, that they are not injured. We have never seen any method so satisfactory as this for transporting apples, and none better for preserving them in good condition until Spring.

But in the multitude of counsellors there is wisdom. A friend of ours has just presented us with a dish of his apples, which are very well kept in his way. He packs them in tight barrels, in the orchard, in the Fall, with the *dry* leaves of the apple trees, a layer of apples, and a layer of leaves. This keeps them from bruising, and the leaves absorb the moisture, and prevent rotting. His barrels stand in a chamber, and do not freeze through the Winter. This method works admirably with him, and is certainly worth trying by those who raise their own apples. (We have known apples packed in leaves, the barrels subjected to very rough handling, to be opened in London, sounder, fresher, and of better flavor, than any imported apples which the person to whom they were consigned had ever before seen, so he reports.)

It is a matter of very great importance to be able to keep this fruit through into the Spring months, in good condition. It is not only a comfort in the family, but adds much to the profits of the orchard. A hundred barrels of winter fruit, worth but $200 in October, will frequently bring $400 or more in March, or April. It is by particular attention to such small items as these, that a farmer gets ahead in the world.

To Abolish Fruit-Stealing.

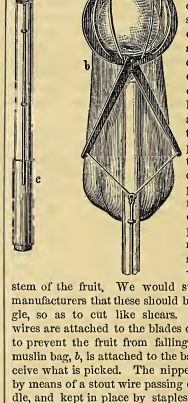
As we grow older (and more charitable?) we are the more inclined to think that the stealing of fruit springs from an ignorant, heedless sportiveness, rather than from deliberate wickedness. They who steal have never learned how much time and labor it costs to raise fruit; and seeing it in tempting plentifulness around, they think it can harm nobody very much if they take a little. We do not justify this, nor do we deprecate the use of legal suasion, at times; but would not a little moral influence and tact also be well? To a family given to purloining grapes, we would send a dish of fruit as a present. Would they not be ashamed afterwards to rob their benefactor? Certainly they would, unless they were heathens. Perhaps, in another case, we would present them with young plants of the grape, or young fruit trees, teach them how to plant, and prune, and train them. Heap coals of fire on their heads. Wouldn't they wince under the scorching!

Uses of a Garden Frame.

A garden frame is very easily constructed. Take 1¼ inch planks—one about eighteen inches wide for the back side, and another nine inches for the front, and each from ten to fifteen feet in length. For ends, use planks of same thickness as sides, about five feet in length, and tapered in width from that of the back plank at one end to that of the front at the other. Cover the inclined top with sashes, arranged to open either by sliding or by hinges. Such a frame is useful in three ways: 1st, in early Autumn, to dry apples and other fruits in; 2nd, at the approach of Winter, to set over a cold-bed; and 3d, to cover a hot-bed in early Spring. The whole cost is about $5, and in forwarding early vegetables alone such a frame will pay on every farm.

Another Fruit-Picker.

At the present rate of invention, varieties of fruit-pickers will soon equal the number of churns or washing machines. Several new ones have been shown at the office of the *American Agriculturist* this season, in addition to those already described in our columns. The one figured here has several excellent features, and appears adapted to the purpose designed. The picking arrangement consists of a pair of large nippers with sharp knives, *a*, which cut the stem of the fruit. We would suggest to the manufacturers that these should be set at an angle, so as to cut like shears. Semi-circular wires are attached to the blades of the nippers to prevent the fruit from falling outward. A muslin bag, *b*, is attached to the back part to receive what is picked. The nippers are worked by means of a stout wire passing down the handle, and kept in place by staples at proper intervals. Near the lower end of the pole or handle, the wire is attached to a tin tube, *c*, which slides loosely upon the handle. This enables the operator to readily move the wire up and down to open and close the nippers. The apparatus is light, neat, well made, and not expensive, the retail price being $1.25. It is manufactured by T. Evans & Bro., Newark, N. J.



Migration of Birds in Winter.

Some species of birds remain in the northern States during the Winter. The crow, the woodpecker, the yellow-bird, a little transformed, and a few others spend nearly the whole year at the north. Beside these, we have a few visitors from Arctic regions, who like our winters better than their own, but can not endure our hot summers. But the majority of our Summer birds go southward on the approach of Winter. It is an old notion that swallows spend their winters here, in sand banks or in mud at the bottom of ponds; and that robins hybernate in hollow trees and in caves in the forests. We have no faith in this. Now and then, a robin or other bird, overtaken by Winter, may spend the cold season here, feeding on seeds and berries, but this is doubtless an exception to the general rule.

For the American Agriculturist.

Preserving Specimens of Birds and Animals.

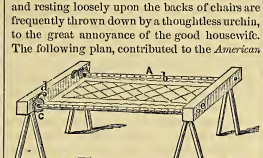
BY ROBERT L. WALKER.

The following plain directions for preserving specimens of birds and animals are given by a practised hand, who condensed them from three or four different processes which he had tried without satisfactory results. Secure the bird or animal with as little injury as possible; sprinkle plaster Paris wherever there is any blood, to absorb it. You will need a very sharp small-bladed knife, a pair of sharp pointed scissors, a pair of wire nippers, a pair of cutting nippers, different sized wires, and glass beads for eyes. You will also need arsenic, powdered plaster of Paris, cotton, and arsenical soap, which is made as follows: Take 8 oz. white oxide of arsenic, 8 oz. hard rosin soap, 1 oz. quick lime, 1½ oz. salts of tartar, 1 oz. gum camphor. Dissolve the soap in a sufficient quantity of rain water by heat, to make a mixture the consistence of cream. Add the arsenic and lime, previously well mixed. Then remove from the fire and add the other ingredients, previously powdered and mixed. Add warm rain-water until it becomes the consistence of good thick cream. Then put into a wide-wouthed jar and cork air tight.

Having every thing ready, we will now proceed to skin the bird. Make an incision through the skin from the lower end of the breast bone to the anus; separate the skin on both sides from the body, until you reach the knee and expose the thigh, take the leg in one hand and push the knee up, and loosen the skin around it until you can place the scissors underneath and separate the joint and muscles. Sprinkle arsenic on the skin to prevent adhesion, loosen the skin about the base of the tail, and cut through the back-bone at the last joint, taking care not to sever basis of the quills; suspend the bird by placing a wire hook in the back or rump, and invert the skin, loosening it carefully from the body. On reaching the wings, loosen the skin from around the first bone, and through the middle of it, or if the bird is small, separate it from the next at the elbow. Continue the inversion of the skin by drawing it over the neck until the skull is exposed. Loosen the ear from the skull without cutting or tearing it. Cut the membrane around the eye-balls, and dig out the eyes, then clean out the sockets, and fill them with cotton mixed with the arsenical soap. Take out the throat, tongue and all other fleshy parts. Then take the brains out from the back part of the skull, which cavity fill with cotton and arsenical soap. Dust every fleshy or bloody place with arsenic. Take a wire the length of the bird, pass it into the skull and out at the tail, then take two pieces of wire and pass one through the wings close to the bone; the other you will pass up through the sole of the foot, along the leg bone and on to the wire in its back; fasten the back wire and leg and wing wires securely where they cross each other. Then force the glass beads or eyes into the sockets. Stuff cotton anointed with the soap into the upper part of the throat. Next make a roll of cotton less in thickness but same length of the original neck, anoint it with the soap, put it into the skin, and push it up to the base of the skull. Fill the body up with cotton anointed with the soap. Sew it up, commencing at the upper end and passing the needle from the inside outwards. Then press the body into its natural shape, bending the wires to suit. Lay it away until it dries and the skin becomes hard. The directions for birds will answer for animals. The incision must commence between the fore legs and extend down to the tail. Be very careful not to stretch the skin. Smooth the fur down, and press into natural appearance.

Convenient Quilting Frame.

The quilting frames in ordinary use are an almost unmitigated nuisance. Except in the largest apartments they monopolize the room, and resting loosely upon the backs of chairs are frequently thrown down by a thoughtless urchin, to the great annoyance of the good housewife. The following plan, contributed to the *American*



Agriculturist by S. A. Newton, Susquehanna Co., Pa., remedies these inconveniences, and also gives a much better means for stretching and holding the quilt to its full tension. The two bars *A* are from 7 to 8 feet long, or a foot longer than any quilt. They should be 2½ inches thick, made eight square, and perfectly straight. A strip of cloth, *b*, is tacked to each bar, to which the quilt is to be attached. One end of each bar is fitted with a rachet wheel, *c*. These rachet wheels are attached to iron caps which fit upon the head of the bar. The pinion of the wheel has one end sharpened to insert in the bar, and the other extends outward through an opening in the horse which supports the bar. The other end of each bar has the cap and pinion without the rachet wheel. The caps serve as bands to prevent the ends of the bars from splitting. The horses are made of convenient hight, with a sufficient spread of legs to stand firmly. Two dogs, *d*, are attached to one of the horses, to work in the rachet wheels, and hold the quilt in place when stretched. The bars of the horses should be just long enough for quilters on opposite sides to reach over the quilt bars and meet half way. As fast as a section of the quilt is finished, another part is unrolled by lifting the dogs and rolling the bars, until the whole is completed. If rachet wheels made of iron for the above arrangement can not be easily procured, they may be made of hard wood, and fitted directly upon the ends of the bars, which could be reduced in size to work in inch holes in the horses.

Something Useful and Ornamental—Newspaper Receptacle.

To the Editor of the American Agriculturist.

We are making an ornament for our sitting rooms, in this part of the country, in the form of a newspaper receptacle. It is so useful, and at the same time so beautiful, that we wish every family had one. Take a common hat-box, cut it down lengthwise into two equal parts, either through the wide or narrow sides. Each half, with half the cover for a back, makes one receptacle. Cover with some delicate color of wall paper. One yard of paper will, with economy, cover three. Put on a border to harmonize with the paper around the upper and lower edges, and sides of the box. Crimson and gold is pretty, with almost any colored paper. Fine gilt leaves—cut out and put on in the form of a vine for a border, are also beautiful. Then look over your old illustrated magazines for a choice engraving, and when you find one to suit you with regard to subject, size, and shape, cut it out and paste it upon your receptacle, taking care to have it directly in the center of the front, equi-distant from the sides and edges. Put a narrow gilt border around the picture, unless it is oval. A square picture, or one that is a little wider than it is long, looks prettiest. Put in three cords, each a yard or a yard-and-a-quarter long, one in front, and one on each side, bring them together and join them with a pair of tassels, or a pretty bow of the cord. The holes for the cord should be made small, and near the upper edge of the receptacle. Put in the newspapers neatly folded, and hang it in the brightest part of the sitting room, just opposite the door that husband or brother comes in at, and you may depend upon it it will add greatly to the attractions of your home. We advise every lady that has not already something of the kind to make one immediately, and henceforth have a place for the last newspaper. GERTIE ELOISE.

For the American Agriculturist.

A Short Story for the Times.*

Best Medicine for a Sick Wife, and How to Obtain it.

"Good morning, neighbor Slack. How do you do? How is your family? you are looking downcast."

"Good morning, neighbor Thrifty. Wife is not very well. I'm not sick, but am rather blue—about discouraged. With the war and hard times, poor crops and wife half sick all the while, its pretty hard getting on. I wish some one would come along and buy my farm; I'd move into the village and try my hand at something else."

"Sorry to find you feeling so badly. Is Mrs. Slack no better to-day?"

"No, and if she was, she'd over-do and get down again to-morrow. We don't feel quite able to hire house-help, and with all her work and her sewing which keeps her up late at night, it's no wonder she, poor woman, does not feel any better. She thinks if she had a sewing machine like your wife's, she could do better, but we have not felt able to buy one. How it is that you keep so forehanded, is more than I can tell. My farm ought to be as good as yours, for it's the same kind of soil and as large; four years ago I thought myself more forehanded than you, and my wife was stronger than yours."

"Just so. When we commenced here the balance was in your favor I am sure."

"Yes, yes, but some folks are born to mis fortune, and that's precisely my case."

"Fortune favors those who favor themselves. I don't believe much in this theory about fortune, or luck. Management is the thing after all."

"Pray give me a hint or two about management. Talk plainly, for I am despondent enough to catch at any word of advice, however plain."

"Well, pretty large results sometimes spring from little things. 'Tall oaks from little acorns grow,' we used to repeat in childhood. My first start was from that extra crop of wheat, four years ago. You know I turned in a great growth of clover, while you fed yours down; and though you sold the most butter, I had a double crop of wheat which brought $1.50 a bushel that year. This put me out of debt, while all the proceeds of your butter went to pay the doctor's bill for your wife, who broke down over the butter bowl."

"That's so. But it was your good luck that led you to plow under the clover."

"No, it was not luck. I read a chapter about the use of clover in my agricultural paper, and followed its recommendations, because they stood to reason.

* We print the above just as sent to us by a Michigan subscriber. We know the machines referred to were called for in the town indicated, and probably the story is not simply "*founded* on fact"—but a literal fact itself.—ED.

My paper cost me a dollar for the year, and that one article gave me ten bushels per acre more of wheat than you get, on the twenty acres, which was so much clear gain, except hauling the extra grain to market. This made me a clean $300 profit."

"Just so, but if your wife had been sick enough to have used up the wheat you would have been as bad off as I. Your good luck favors you."

"But she had no butter to make for market, and that saved her strength. I have tried in various ways to save her strength as well as my own. She has a machine that does up our sewing in short metre, and she goes to bed and sleeps and rests, instead of stitching until midnight, and feeling dull and mopish in the morning and all day. She also has her machinery to help on washing day, and does not complain of lame shoulders from wringing out clothes as she used to do."

"But how did you buy them, if you first paid up your farm debt with that extra wheat crop?"

"I earned them at odd spells. Don't you remember I called one evening two years ago, and asked you to subscribe for the agricultural paper? I was going to tell you about how it helped me, but you bluffed me off short by saying 'you didn't want any book farming.' I was offended and did not press the matter, but I went to others and kept at it, and wife helped me among the neighbors, and her sister in ——— also helped, and so we finally made up a club of 130 names, and received our sewing machine as a present or premium. The editor gave it to me for my trouble, and the only expense was $1.75 for freight. Last year I got over a hundred names again, and received a subsoil plow for myself, a wringing machine for my wife, and some agricultural books besides, which furnished good and instructive reading. It would do you good to come over on Monday and see wife wring out her washing in a few minutes, without ever getting tired. This year I am going to get a washing machine while the editor speaks well of it in his premium list. I begin already to see good effects from my subsoil plow also, and the other new thoughts and hints I have been getting from the paper all along, have made me think more, and farm more with my brains, as Tim Bunker says. Wife reads the paper also, and says she gets many good hints about her work."

"I see it all. I am sorry I answered you so sharply about book farming. Pity you did not call on me again when I was in better mood. But its all my own fault, and it's too late to remedy the matter now. If I can raise a dollar I must have the paper at any rate. Put me down on your list any way, and I'll get the dollar for you to-morrow."

"Not too late, as it happens. I have got twice as many names now as I need to get the washing machine, and I had thought about trying for the Cyclopædia premium, that is, 16 large books containing information about every thing. But I am very busy this Fall, and I'll give you the list of surplus names. With a little effort evenings and at town meetings, and going out of the town, you can soon make up a list large enough to secure your wife a sewing machine. It will be the *best medicine* for her, I am sure. If you can't get the 130 names at 50 cents each, you can at least get 90, and pay the extra 20 cents on each yourself, if necessary. You can see the list of premiums in my paper, which I will lend you until you can send to the editor for a sample copy which will be forwarded for 10 cents, or even free, if you promise to use it in getting up a club. You can do best by hurrying up the matter now, for the Publisher of the *American Agriculturist*, (New-York City,) offers it the rest of this year free to all names sent in soon."

"I am very much obliged to you, neighbor Thrifty. I'll come over early this evening for the paper, and any instructions you can give me about getting names. Good morning. I will take new courage, and wife will too, when I tell her about the new medicine. The hope of it, will do her good. I have got a new hint. I have complained of ill luck in having a sickly wife, and many a man has broken down under this. But it's my own fault. I ought to have got labor-saving implements for her, as well as for my own work. She has broken down under day and *night* labor—sitting up until midnight to finish her sewing, while I have slept and rested. It shall be so no longer. Thank you again for your plain, instructive talk. Good morning."

Middlings, Shorts, etc.

Several contributors to the exhibition of Corn Bread, intimated that rye flour is quite as good as wheat for mixing with corn meal for the manufacture of cheap, sweet and wholesome bread. This is probably true, excepting as respects color, and that should be a secondary consideration. One contributor has commended wheat *middlings* as better than fine flour, saying that the last running from the bolter above the bran was intended, but suggesting modestly that we might substitute a more suitable term. That would be impossible. *Middlings* is just the word. It means, neither very coarse nor very fine, but half way between the extremes. As applied to the products of wheat, it has been long used to designate that which is finer and of lighter color than the bran, but darker and coarser than the flour. The products of a bushel of wheat are sometimes distributed by the miller into as many as seven grades. In ordinary bolting for family use, seldom are more than four grades made, and oftener perhaps but three—the flour, the middlings and the bran. If, on this principle of distribution, the miller should return, for a bushel of wheat, 25 lbs. of flour, 20 lbs. of middlings, 12 lbs. of bran, it would be evident that some of the flour and some of the finer parts of the bran had gone together to make the middlings. This shows what middlings are; but to ascertain their value, as food, we need to examine the kernel of wheat, to see of what its several parts are composed, and which of its parts go to make up the middlings after grinding. First, there is the body of the kernel, consisting very largely of starch. This is surrounded by a 3-fold coating, outer, middle and inner. The outer coating is little else than hard, woody scales; the middle contains much gluten; and the inner, which is quite thick, is almost wholly of gluten; while the enclosed interior as we have said above, is principally starch, having a little gluten disseminated among its particles.

Now it is manifest, that if we grind and bolt wheat so as to make but two grades—fine flour and bran, the entire substance of the skin goes with the bran, and never finds its way into the bread tray; whereas, if we make some twenty pounds to the bushel of a middle grade, we save the glutinous inner coating; and whatever of food value there is in the middle coating is saved. These, together with a little of the fine flour, make up the middlings, darker in color, but more palatable than the flour, and of far greater value as food, because they contain more gluten, this being the only substance in wheat which supplies material for the tissues of the body, especially for the muscles.

Bread made of wheat middlings, or of these with one half corn meal, gives to the human form a more perfect development, more health, strength, symmetry and beauty, than that made from fine flour, and would sustain life much longer, if used as the only food. The finest bread is not the best for common use. The whitest is not. That which contains most of the matter of which bone, sinew and muscle are made, will make better developed men and women. Especially will it be so, if we supply it to our children in the growing period. We therefore vote for a full supply of *middlings*, and for a good share of corn meal in the batch. Wheat contains hardly oil enough to make it the best constant food. Corn contains rather too much. Mixed in equal portions, they are about right. Let us honor the brown loaf. We should forget the whim, that whiteness and fineness are the only qualities of good bread, and let us look rather for what will make vigorous, stalwart men, and strong, healthy and beautiful women.

Don't Buy a Pound of Butter.

Buy a firkin or a pail of it at a time, now that cool weather allows of its being kept sweet for a long period. This advice is intended for the very large class of readers of the *Agriculturist* who live in cities and villages, many of whom buy their butter at the grocery only as it is needed from day to day. This is an extravagant practice. Butter, for which the farmer would gladly receive from sixteen to twenty cents, according to the season, costs the purchaser from twenty to twenty-five cents by the small quantity. But, aside from this, grocery butter is seldom of as good quality as that purchased directly from the producer. Dairymen and women are really not as particular with butter "for the store" as with that made for private customers. "What is the use of *my* taking pains," says Mrs. Perkins, "when my butter will be put with Mrs. Slack's, and Mrs. Hasty's, and a dozen more lots of poor stuff. It won't bring any more, and I shall get no credit." But order a pail from Mrs. Perkins, and she knows that unless it be good, she will hear from it. Then, too, the butter for sale at the grocer's has often been brought from a distance, exposed to the heat, and in retailing, it is opened to the air, and subjected to the not over-nice manipulations of the clerk in weighing, etc., and by the time it reaches the table its glory is departed. Almost all our readers have some acquaintance in the country from whom they can engage a supply of butter for the Winter. Now is the time to do it. Butter made from the sweet after-growth of the meadows, before the frost has partially withered the grass, and while the weather is cool, if properly worked and packed, will keep sweet until next Spring. Send to such an acquaintance an order for what will be needed, with directions to have it packed in stone jars, or in new sweet firkins, and you will rejoice in your foresight over every plate of well-buttered "buckwheats" during the Winter.

"Old Maids."

We heartily endorse the following kindly words from the pen of Henry Ward Beecher, in behalf of a class whose good deeds have never been appreciated. He says: "I have no sympathy with that rude, unfeeling, and indelicate phrase, *old maid*, which is bandied about in the mouths of rude, unfeeling, and indelicate persons. It is true that a selfish nature, cut off from all duties and ties, and sinking back into the solitary life of a selfish heart, becomes most unlovely, and useless. But shall the few cloud the true nobleness of the many? How many elder sisters, it may be unblessed with outward comeliness, have entered into a brother's or a sister's family, and accepted all its cares as the duty of their life, and, joining hands with the mother, given to each child, as it were, two souls of love, like two wings of God, to help it fly up withal from weakness and ignorance to manhood and strength! How many have cheerfully given up their own whole life, built no nest, sought no companion, but sang in the tree

and near the younglings of another's nest, patient in toil, watchful and laborious in sickness, frugal amidst poverty, rich in nothing but good works, and in these abounding in wealth! When the roll is read above, and they are named that lived in self-sacrifice, in gentleness, in patience, in love, and in the only triumph of disintcrested mercy—they who are unmarried and childless, that they might more heroically serve the households of others, and become mothers to children not their own—shall stand high and bright."

The "Corn" Crop.

Not Indian corn; but a less profitable crop, one which causes more vexation than any other crop of its size. The crop of toe-corns is a slow, but a very sure crop. It grows with equal facility in all climates and in all seasons. It springs up on the feet of youth, gains strength in older soil, and culminates in the bunions and stiffened joints of old age. Like dock weeds, brambles, and other nuisances, it grows where not wanted, with the difference, however, that those cause no pain, while this causes much. Why are corns raised? Look at your children's toes, and the answer is plain. Parents and shoemakers are responsible. Two causes contribute most largely to their formation and growth; 1st, shoes too tight. 2nd, shoes too loose. For every corn caused by loose shoes, a thousand are caused by shocs too tight. Most parents are stupid enough to think that the beauty of a child's foot is increased by making it appear small. It is strange that such nonsense should prevail this side of China. The young feet are cramped into shocs of the villainous "stump-toed" fashion of the present day; so short in front, that they compress the toc-nails, causing them to grow inwards, and thus give great trouble; and so narrow that one or two toes are piled upon the others, instead of being allowed to touch the sole of the shoe, as they should. Each step taken helps on the corn. When the shoe is taken off at night, you may notice certain little red spots, which, however, fade away after the child has kicked about the bed for half an hour. These are the foundations of corns. When that child is twenty years old, they will give trouble; and perhaps even long bcfore—if not remedied now.

If you plant your child's naked foot upon a piece of paper, and make a pencil mark round it, you will be astonished when you compare the diagram you have drawn with the size and shape of the sole of the child's shoe. You will say at once that you will have no more such shoes. That is the only safe conclusion; act upon it at once. Tell the shoemaker that he shall make no more shoes for your child, unless he will consent to adopt the model of the foot, instead of the wooden thing which some blockhead has made to take its place; and insist, as an *ultimatum*, upon their being large enough, but not too large. T.

Slings for the Wounded.

MR. EDITOR:—May I say a few words on the subject of slings? I have lately met several men with their arms tied up in the most uncomfortable slings. They looked like returned soldiers, and I *longed* to go up to them and say "my dear friend, *do* let me tie your sling more comfortably," but fearing they might think me an escaped lunatic, and take to their heels accordingly, I resolved to say a few words through the columns of the *American Agriculturist*, hoping they might meet the eye of "mother," "wife" or "sweet-heart" who might have the care of some poor wounded one: Let the handkerchief be *large*; tie the sling in the usual way, and *then pull out the fold, until it extends from the elbow to the hand*, supporting both, as in a cradle. AUNT SUE.

An Incident—A Genuine "Lady."

A correspondent of the Presbyterian, relates at some length an incident he observed on the cars, while on his way East to Pittsburg. We condense the substance for the *American Agriculturist*. Our lady readers will not need to have the moral appended. On one seat was a pale soldier, lean and weak, returning, as it proved, from service in Arkansas, to be nursed by his mother, near Pittsburg, whose only son he was. At Wellsville, most of the passengers got out for refreshments. Some passengers carried food along, and ate it in the cars, but none offered any thing to the soldier, who, either too weak to walk, or not having money to spare, sat still, silent and alone. As the train was about starting, two middle aged ladies came in, and opening a basket began to eat a bountiful lunch. From their conversation they appeared to be from New-England. They were richly dressed, and judging them to be aristocratic, the writer was not favorably impressed with them. After a little while, one of them casting her eye forward saw the soldier. She stopped eating, and whispering a moment to her companion, who nodded assent, she went forward and conversed pleasantly with the soldier, and returned for her basket from which she supplied him liberally with the best it contained. After eating all he desired she wrapped in a paper and gave him enough to last him home. After eating the remnants in the basket herself, she sat down by his side and talked pleasantly with him most of the way to Pittsburg. The writer conceived there were few dry eyes among those who saw what passed. Was not that woman one of the true aristocracy? Whether the needed food, or the kind manner and conversation of the lady was most refreshing to the long-time homeless patriot, or whether both were not equally so, we leave the reader to decide.

Brown Bread.

Mrs. Henry Green, Saratoga Co., N. Y., sends the following which she thinks will be found superior to any thing yet published in the *American Agriculturist*. (We know that a very similar preparation *is* good.): Mix 3 pints of sour milk or buttermilk, ½ cup molasses, 1 tablespoonful salt, 1 tablespoonful soda or saleratus, 5 cups of wheat or rye flour, and 5 cups of Indian meal. Put it in a pan, about 3 inches deep, and bake three hours in an oven heated as for wheat bread.

Salting Down Meat.

"Whistler at the Plow," sends to the *American Agriculturist*, his method of salting meat, which he considers much preferable to the common practice of putting it into a brine or pickle at first. A bench is prepared with one side lower than the other, inclining say 25° to 30° from a level. The meat is cut into pieces to suit convenience, fancy, or utility, and salt is thoroughly rubbed into every part of it—into all the joints, hollows, etc. It is then laid flesh side down upon the inclined bench, so that all water may drain off. The rubbing in of dry salt is repeated three or four times during ten or twelve days, after which it is laid down in pickle in the usual manner. Mr. T. claims that by this dry salting the blood and other fluids are drained off, and the permanent brine is cleaner, sweeter, and will preserve the meat longer, and in a much more palatable condition. [We can scarcely decide upon the value of this plan. In cool weather, or in a cool room, it would work. The meat would be apt to spoil if exposed long in warm air.—ED.]

Hints About Cooking, etc.

Dressing for Turkeys, etc.—Contributed to the *American Agriculturist* by Mrs. "J. N. P., Keokuk, Iowa. Take stale white bread, crumble it fine, and moisten with boiling milk. Add about 2 ounces of butter to a pound of bread, the yolks of two hard-boiled eggs, a little parsley, and half a lemon peel, all chopped fine; season with pepper, salt, and sweet marjoram. Mix altogether with two beaten eggs. A little flour and water mixed with the dripping, if not too fat, will make good gravy. The above stuffing will be found to answer admirably for roast chicken, veal and lamb.

Puff Pudding.—Contributed to the *American Agriculturist* by "Charley Clover," Elizabeth, N. J. Take three eggs, nine tablespoonfuls of flour, a pint of milk, and salt to taste. Pour the milk on the flour scalding hot, then add the eggs. Bake from twenty minutes to half an hour. Serve with sauce to suit the taste.

Green Tomato Pickle (Sweet).—Contributed to the *American Agriculturist*, by "E. E. J.," Lisbon, Va. This pickle is very popular with us Virginians, and is thought to be particularly nice with muttou and beef, or any kind of fresh meat. Gather full-grown green tomatoes, scald and peel them. Make a strong ginger tea, into which drop your fruit and scald well. For every two pounds of tomatoes, take a pound of sugar and a pint of good vinegar, and make a syrup of this, and drop in the fruit. Let them cook until perfectly clear. Add cinnamon, mace, and white ginger. Cover well with syrup, and tie up closely.

Good Apple Sauce.—Contributed to the *American Agriculturist*, by Viola Homespun. "Peel, quarter and core as many apples as you wish to cook; put them in a tin or brass vessel with just water enough to cook them tender. While they are cooking, have a tin cup or some other small vessel on the fire, with about half a pint of water, one tablespoonful of butter, one of sugar, about ¼ of a nutmeg grated, with this rub, stir in enough paste (thickening) to make it of the consistency of cream; put your apples in a dish and pour this over them, and if you are fond of apple sauce you can't help liking this."

Meat Pickle or Brine.—A Michigan subscriber sends to the *American Agriculturist* the following which he recommends as good: To each gallon of water add 1¾ lbs. coarse salt; 1 pint molasses, or 1 lb. brown sugar; 1 ounce saltpeter, and 1 teaspoonful of saleratus. Bring it to a boil, skimming thoroughly just before it begins to boil. Let it cool, and then pour it over the meat until entirely covered.

Preserving Hams.—A subscriber (A. Miller,) objects to smoking hams to preserve them, and recommends in its stead, a coating of pepper and flour—1 pound of the pepper and 3 lbs. of flour, well mixed together dry, to 500 lbs. of meat. Rub thoroughly on the flesh side, and also where the leg is severed from the ham. He affirms that this will keep insects from the meat, and obviates the strong taste resulting from smoking, besides being more easily and cheaply done. [The pepper may keep off insects, but most persons like the smoky flavor, and the smoke acts as a prescrvative. Salt toughens meat; and when hams are smoked, less salt will be required.—ED. *Agriculturist*.]

To Preserve Lamp Chimneys.—One who claims to have thoroughly tested it, recommends to toughen glass lamp chimneys, by putting them in lukewarm water, heating the water to boiling, and then cooling slowly.—All glass-ware is, or should be, baked in an oven and slowly cooled when first made (called "annealing"). If this were neglected, the above operation may be beneficial. We suggest, however, that the annealing will be best done, and be more lasting, and continuous, if always before putting out the lamp, the wick be turned down gradually, so that the chimney will cool off somewhat slowly.—*American Agriculturist*.

The Editor with his Young Readers.

LETTERS FROM MR. JUDD....NO. III.*

LONDON, *England, July 9th*, 1862.

DEAR YOUNG READERS:—I have sent you a letter to-day, but while everything is fresh in mind, I will write you a little about this, the largest city in the World. London has nearly three million inhabitants, or about three times as many as dwell in New-York City proper, though New-York would be almost as large should it stretch out its arms, as London has, and absorb the cities and villages joining it—Brooklyn, Jersey City, Newark, Hoboken, Hudson City, etc. Indeed there are nearly as many houses in a circle 12 miles from the center of New-York, as in the same circle drawn around the center of London. For 23 days I have visited the surrounding country, and the public places travelers usually visit, while in the evenings I have often spent many hours going through the streets, and lanes, into the public places, the beer saloons, the shops, etc., to see what the common people were about, what they talked about, etc., and how they spent their leisure hours. Indeed, I feel better acquainted with London than with New-York, for I am seldom in New-York at night when the masses are not at work.

Herewith is a rough outline Map of London, that I have hastily sketched to give you an idea of the City, or the location of the principal points of interest. The sketch embraces 12 miles from West to East, and 8 miles from North to South. The dark shade shows the thickly settled portion, which extends 7 to 8 miles west to east, and about 5 miles nortl. to south. The large white spots represent the great parks. The largest white line shows the Thames river (pronounced "*Tems*" here) coming in from the West, winding through the city, and bending in a sharp curve south to Greenwich. After leaving the city it runs away southeast, some 60 miles, to the sea. Most of the city is on the north side of the river. The larger white lines (1, 2, 3, 4, etc.,) represent the leading thoroughfares; the small lines give some idea of the great number of short streets running in almost every direction.

The reference letters and figures under the map will tell you the location of the many places you have read or heard of, such as Bank of England (*A*); Post Office (*B*); St. Paul's (*C*); Tower of London (*T*); Thames Tunnel (*p*); British Museum (*G*); Parliament Houses, on the river (*K*); Buckingham Palace, the Queen's City residence (*M*); The Great Exhibition (*P*); Hyde Park (*N*), Kensington Park and Gardens (*O*); Regent's Park (*H*); Zoological Gardens (*J*); Victoria Park (*W*); the London Docks (*U*); Greenwich with its Observatory whence longitude is reckoned (*V*); etc. Please study the references, and preserve this map to look at as I describe some of these places more particularly hereafter.

The Streets of London are very irregular. There are no Broadways or long Avenues, as in New-York. The long white lines I have drawn for *thoroughfares*, are not crooked enough and do not turn as short corners as do the streets, and they do not vary enough in width. Take, for example, the longest thoroughfare from east to west (1, 2, 3, 8). This is really made up of about twenty streets running mainly east and west, the end of one meeting the end of the next. Thus at fig. 1 it is called Uxbridge Road; further west it is called Kensington Terrace, then Notting Hil. High Street; further east (at fig. 2) it is Oxford st., then New Oxford, then High Holborn (at fig. 3), then Holborn, then Holborn Hill; then it turns sharply to the southeast and takes the name of Skinner st., then Newgate, then Cheapside, then Poultry st.; from the Bank (*A*) eastward it is Cornhill st., next Leadenhall st., then Aldgate, and so on eastward through White Chapel High st., White Chapel Road (at fig. 8), Mile End Road, Bow Road, etc. This thoroughfare changes its width and direction so often that you would be puzzled at first to follow it through the city from the west to the east side. The same is the case with all the other thoroughfares, which for convenience we have represented by larger white lines.——There are a great many streets of the same name—a dozen or more King streets, for example. To indicate *which* street is meant, they use two names. The city is also divided into Postal districts, C, W C, E C, W, N W, N, N E, E, S, etc., meaning the Central, West Central, East Central, Western, North western, etc. My letters come directed to "No. 11 Upper Kings street, Bloomsbury, London, W C." This tells the postman that he will find me on that one of the Upper King streets which is near Bloomsbury Square, and is in the Western Central (W C,) division of the city. If it was "No. 11 King's Street, Cheapside, London, C.," he would go to the Central (C) portion of the city, and find that one of the King streets nearest to or running out of Cheapside st. You will often see London advertisements, or business cards, where the location is described by two names, the first the street, and the second indicating what other street or place it is near. *Old London* only occupied a small space along the river from *p* to *g*. Many little villages sprung up in the suburbs, such as Pimlico, Brompton, and Chelsea, on the southwest; Kensington, Hammersmith etc., on the west; Kilburn and Hampstead on the northwest; Somers, Camden, Kenfish, Holloway, Isling ton and Highbury, on the north; Haxton, Kingsland, Dalston, and Hackney on the northeast; Globetown, Old ford, Bromly, Limehouse and Poplar, on the east; and Southwark, Rotherhi, and others, south of the river. All these were within the country covered by our map. Each of these towns had its own streets, and when they were all absorbed into London, the streets of the *same name* were necessarily distinguished, as above described.——Some of the names sound oddly to Americans. Here are a few Post Office addresses, I gather from the first pages of a directory: "Amen Corner st., Paternoster Row,"—"Angel Alley street, Bishopgate-without,"—"Bear Yard, Lincoln inn Fields" (this happens to be the *lawyers'* quarters)—"Black Bull Yard, by Peter's Lane, near St. John st."—"Black Raven Court, Seething Lane,"—"Cain Place East, Nags Head Tavern"—"Boar's Head Court, Bolt in tun Tap Tavern," etc. These are the actual business Post Office addresses of individuals, and I could give you a hundred others equally curious. Mr. Spurgeon's Church, for example, is on "Newington Butt's street, near the Elephant and Castle Tavern." (This is in South London, near where several thoroughfares meet, two-thirds of a mile south of Blackfriar's Bridge, *th*,

* Though the writer has returned, we continue these letters just as prepared abroad, at the time of their date.

London is not a neat appearing city, either in its streets or buildings. The smoke from the *three million tuns* of bituminous coal burned every year, and the almost constant fogs, fill the air, soil everything, and give the whole city a dingy look. I have seen the sun but a few times here. It has been foggy or rainy nearly every day. On what promised to be a fair day I went to the top of St. Paul's (*£*), but after waiting for hours, was unable to see beyond a few squares. The people are so accustomed to this kind of atmosphere that they think nothing of it. I have but once ventured far from my rooms without an umbrella and rubbers, and then got thoroughly soaked.

There are here no large hotels like the Astor House, St. Nicholas, and Metropolitan, of New-York. The hotels, such as they are, are kept on the European plan, that is, you pay for your room, for servants, and for whatever you call for, and no more. At the restaurants you call for what you want, and pay for the items, the meat, the bread, the butter, the potatoes, etc., and then pay the waiter separately. Most travelers stopping here a week or so, take what are termed "Lodgings," or "apartments." Thus: I have a neat furnished parlor and bedroom (by chance in a very good and kind family), for which I pay about $5 a week. This includes rooms, and care of them, and the *cooking* of my breakfast. I order from day to day what I desire, naming the items, and my hostess procures them for me, and charges me just the cost of each item. One can live as cheaply or as expensively as he desires. The dinner and supper are usually taken at restaurants, wherever one happens to be when hungry. This is the way most visitors live while in London—they in fact "keep house," and have a home for the time being.

Having now given you a general idea of London as a whole, I will briefly describe some noteworthy objects.—There are more than fifty of these in and around the city, but I can allude to but few in this and another letter. Don't forget to study their location now by the map and index underneath, and to preserve the map to read with the closing part of this letter another month. You will thus get some idea of London, whether you ever visit it or not. The city contains as many people, as each of several entire kingdoms in other parts of the world, and therefore deserves as much study.

The Thames is an important river for so small a stream. Along through the city it is scarcely more than 30 to 40 rods across—in some places less. It is spanned by twelve or thirteen bridges, some on stone arches, two on iron arches, and four or five suspended on wires, or iron bars. The most famous is London Bridge, the one next lowest down stream. It is 54 feet wide, 928 feet long between the tops of the banks, and has 5 great arches. No masted vessels go above this bridge. Small steamers ply above, loading and receiving passengers at the various piers. These are provided with jointed smoke pipes which are let down (tipped back) on approaching a bridge. Barges, and boats with short masts to be lowered, go up the stream, but there are not half so many boats on the river as I expected to see, from the descriptions given by travelers.

Large docks come up the Thames below the bridges. Artificial Basins or "Docks," are built inland, with short canals opening into the river, and provided with gates. At high tide the ships are floated into the docks, and the gates are then shut, to retain the water as the tide falls. The ships therefore lie right among the storehouses to unload and load, and go out at high tide. Some of the docks or basins are very large. By this means the narrow river accommodates a very great amount of shipping. It is a Channel, or sort of Ship Canal, from the docks out to the sea.

(*To be continued.*)

Fowl Proceeding—A Question for Discussion.

MR. B. and Mr. P. entered into partnership under the following circumstances: Mr. P. had a setting hen, and Mr. B. had eggs, which were to be placed under the hen, and the profits divided equally. But alas, "the best laid plans of mice and *hen* gang aft agiee": The chickens didn't come out exactly as looked for, as appears by the following letter from Mr. P.:

DEAR B.—I regret to inform you that our eggspectations regarding the Bramah chickens are frustrated. The old hen was manifestly averse to entering into the fruition of others' labors—or else was eggshausted by the fruitless hen!eavor to incubate on an empty nest for two or three weeks prior to the arrival of our partnership. Well—it was too eggsacting a requirement of the poor hen in such hot weather. She deserted her nest—we replaced her time and time again. She grew more and more averse to being forced into maternity. At last we shut her into the nest, and when we went again, there she was "a settin' standing." Now what to do with the eggs? Is it your understanding that the partition of profits begins with the setting of the hen? or only with the hatching of the chickens? If the former, I will defer to you in the choice of your half of the eggs. If the latter, I have no claim, except for storage, say $1. Under the eggsisting circumstances, I confess myself chicken-hearted, and beg that you will not again seduce me into any such fowl proceedings. Yours in misfortune, P.

NOW MR. B. says two things are to be considered in a settlement. 1st. He has lost his eggs. 2d. Mr. P. has lost the time of his hen. But, as she was represented to be a good setter, he thinks it a plain case of obtaining goods under false pretences.—The whole case has been referred to us for arbitration, and we submit it to the jury of our readers for home consideration.

A Hint to the Boys and Girls.

Many of our enterprising club gatherers have enlisted for the war, and there will be in many places a fine opportunity for the Boys or Girls, who have hitherto been crowded out by older competitors. Suppose you look over the General and Special Premiums on this page, and one last one. There are some Good Maps you want at once. Then, there are Good Books; a Clothes-Wringer, or Washing Machine, or Sewing Machine for mother; a Barometer for yourselves; Melodeons, Cyclopedias, fine Back Volumes of the *Agriculturist*, the Portfolio File, to keep your numbers in, Paints, etc. Hundreds and hundreds of boys, and girls too, have got one or more of these premiums in previous years. Who will get them this year? *Answer:* Those enterprising boys and girls, who are to make our go-ahead farmers, business men, good housekeepers, etc., hereafter. The extra numbers offered to *new* subscribers now, will be an inducement to them to subscribe in your club, at once.

Problems and Puzzles.

No. 18.—*New Rebus.*—A true saying. What is it?

Answer to Scriptural Rebus, No.17, (page 281, September). "Go to the ant thou sluggard, consider her ways and be wise," which is expressed thus: Goat too th e ant t house lug guard c on cider her vase and b y's.

Answer to Typographical Puzzle (page 281, September, "If the grate be empty, put coal on (:); if the grate be full, stop putting coal on. The servant's reply was, "How can I put coal on, when there is such a high fender?"

Correct answers to the puzzle in the September No., have been received from Charlie D. Bingham, "A. B. C.," Samuel Campbell, Manly L. Osborne, Charles A. White, "L. L. M., jr," H. P. Hart, H. E. Hart, A. L. Ballou, G. Frederic Sly, T. J. Craig, T. S. Peck, Wm. S. Norton, Frank, C. G. Calkins, G. A. Cunnington, John Craig.

PREMIUM LIST, For 1863---Volume XXII.

New Subscribers get the Rest of this Year Without Charge. (*See page* 320.)

Good Pay to Voluntary Agents who attend to Collecting and forwarding Clubs of Subscribers to the American Agriculturist.

(Premiums open to all who Desire them.)

Every subscriber is invited to renew his own subscription, and to solicit others to subscribe. But to all those who will take the trouble to collect and forward CLUBS of subscribers, we offer a remuneration in the form of *first-rate* articles, as named below. The pay thus offered is much larger than we could pay in cash, though no article is proposed which is not of the best quality, and fully worth the price asked. We get these articles on extra good terms *when for premiums.*)

Part of the Premium articles announced this month are selected from the best given last year, those which gave universal satisfaction. They are such as will *pay* for the effort to obtain them.

☞ WE WISH IT DISTINCTLY UNDERSTOOD *that these premiums are offered in good faith—no cheap, trashy, imperfect, poorly made, or second-hand thing, will be sent out, but each article offered, is the best of its kind, and every one will be selected by the publisher from the very best manufactured. They will be the best sold in the market at the prices named.*

☞ We offer nothing *for competition.* Each premium is for a specified number of subscribers, and no one's remuneration will depend upon what other unknown persons are doing; every one knows just what he or she is working for.

☞ *We make no distinction between new and old subscribers* in giving these premiums, but it is expected that every canvasser will not only gather up the names of old subscribers, but also secure a large number of new names.

☞ Every person collecting names for premiums, should send two copies of each list of names—one of them marked "For Premiums," and also with the name of the sender.

☞ Every person collecting names for premiums, should send the names with the money as fast as obtained, so that the subscribers may begin to receive their papers; but if designed for premiums, two copies of each list of names should be sent—one of them marked at the top "For Premiums," and also with the name of the sender.

☞ The premiums are offered for subscribers for Volume XXII (1863), *whenever received.* Canvassers will have time for completing their lists, but the premium will be paid as soon as any club is made up—if duplicate lists are sent.

☞ Any person who has commenced sending in names at 80c. and finally fails to get the higher number of names, can fall back upon the smaller number, by remitting the 20 cents extra on each of the smaller number of names required.

☞ Clubs need not be all confined to one Post Office.

Table of Premiums for 1863.

Premiums.	Price of Premium.	Names at 80 cents each.	Names at $1. each.
Names of Premium Articles.			
1—Good Books—*See terms below.*	$7 50	18	37
2—Nonpareil Washing Machine	$14 00	30	70
3—Sewing Machine, (Wheeler & Wilson)	$45 00	90	150
3—Sewing Machine, (Wilcox & Gibbs)	$35 00	69	98
4—Aneroid Barometer	$7 50	18	34
7—The Aquarius	$10 00	22	47
8—Five Octave Melodeon (best)	$75 00	150	225
9—4½ Octave Melodeon (best)	$60 00	104	192
10—Four Octave Melodeon (best)	$45 00	90	150
11—New Cyclopedia, 16 volumes	$18 00	96	140
12—Webster's *Unabridged* Dictionary	$7 50	18	35

24—Eagle Plow No. 2	$8 00	26	58
24—Hay and Straw Cutter (best)	$8 00	26	58
25—Steel-tooth Cultivator (best)	$6 00	24	55
26—Family Lard and Wine Press	$7 00	24	55

DESCRIPTION OF THE PREMIUMS.

Premium No. 1—Good Books.

This premium will meet the wants of a great number of persons. On page 285 is a list of 36 books, many of them on topics connected with the Farm, Garden, and Household, and a portion of them the very best published. (See remarks at the head of that list.) Any person sending in 16 or more subscribers, may select any of the books in that list, (page 285,) to the amount of 12½ *cents for each name, at the club price of 80 cents, or to the amount of 25c. cents for each name, at* $1 *each.* Many farmers' clubs have, during the last year, joined together and obtained a considerable library through these premiums. N. B.—The books will be *delivered* to the recipients, (by mail or express, *free of all cost.*

No. 2—Family Clothes-Wringer.

This is a first-rate household implement—a great saver of garments, and a saver of hard work. Every woman knows that wringing by hand is not only the hardest, wrenching work of washing-day, but that the twisting by hand-wringing breaks more of the fibers of the garments than the washing and ordinary wear. With this machine set upon the edge of the wash-tub, the garments are easily and rapidly passed between two India-rubber rollers, the water falls back into the tub, and the garments dropping into a basket, in a drier condition than they can be wrung by hand, and therefore more quickly dried on the line. A child can in a few minutes bring out a tubful of clothes. The machine will save its cost several times in a year, simply in the saving of garments. We have had one of the first machines made in constant use in a family for nearly three years, and it is still as good as new. The machines now manufactured are still better, several improvements having been made. The machine offered, No. 2, is the best thing for family use. It is provided with cogs to move the rollers together, so that it is not possible to tear garments, as is the case with cheaper Wringers not provided with cogs. We present one of these No. 2 Wringers to any person procuring and forwarding 18 subscribers, at $1 each, or 37 at the lower club price, (80 cents each.)

Premium No. 3—Best Washing Machine.

Many ladies have asked us, for years past, to introduce a good Washing Machine among our Premium articles, but we have uniformly declined doing so, for want of the right kind of machine. We have now, however, found a machine worthy of a place in the premium list, in which we mean to put none but those known to be first-rate articles. The **Nonpareil Washing Machine** we have had in use in our family for nearly a year past, and it has not only driven out half-a-dozen placed there on trial, but has really given excellent satisfaction. It is the only machine, out of twenty we have tried, which the "help" cheerfully use without compulsion. It is a labor-saver and a clothes-saver—two important considerations. (See description, and advertisement on page 319.) The clothes are put in, in quantity, and quickly washed by simply turning a crank. The balance-wheel adjusts the force required, so as to make the turning easy. Take it all in all, it is the best Washing Machine we know of and is worthy of a place in every family. They are of three sizes; we select No. 2, as the best size for common family use. The price of No. 2 is $14. This machine we will present to any one forwarding 30 subscribers at the regular price, ($1 each,) or 70 subscribers at the lowest club price, (80 cents.) The machine can be sent to any point as freight, or by express, and will be forwarded, rec of all expense, except the freight after leaving the city

Premium No. 4—Sewing Machine.

90 Subscribers at $1 each, (or **130** at 80 cents each,) will entitle the person sending them to *Wheeler & Wilson's* best **$45 Sewing Machine,** (including **Hemmer**), new from the factory, and of the very best make. There is no better family machine than this made, as we have proved by nearly *five years'* use in our own family, in connection with other machines. We want no better. The fact that more of the Wheeler & Wilson machines are sold than of all others combined, is perhaps the best testimony in their favor. The terms on which it is offered above, will enable many families to secure one without direct outlay of money. The Premium Machines will be selected new at the manufactory, and will be forwarded, well boxed, with full directions for setting up and using, and with no expense, except for freight, after leaving the city.

Premium No. 5—Sewing Machine.

69 Subscribers at $1 each, (or **98** at 80 cents each,) will entitle the person procuring them to a *Grover & Gibbs'* **$35 Sewing Machine,** including a set of **Hemmers.** This is the best machine of its kind, (sewing with one thread,) and has several points superior to other machines. It is neat, well made, simple in its operation; and having tested one in our own family for more than two years, we think highly of it, and can recommend it to those who can not afford to buy the higher priced double-thread machines. Some of our neighbors think this machine ahead of all others. Premium 5 will be selected and sent the same as No. 4.

Premium No. 6—Barometer.

19 Subscribers at $1 each, (or **44** at 80 cents each,) will entitle the person getting up the club to one of *Kendall's* **Ancoid Barometers,** (figured on page 313.) This neat, portable Instrument, and valuable to every person as a weather guide, as well as for scientific purposes. We have had one in use for nearly three years, and find it not only accurate, but an admirable weather prophet. Scarcely a rain storm or gale of wind has occurred, that has not been heralded by our barometer. It will save to the farmer and others many times its cost, as a weather-indicator. These instruments resemble a large watch, 5 inches in diameter, and 2 inches thick. Each one is in a neat leather case, and when sent to a distance, this is packed in cotton, in a wooden box 4½ by 8 inches, and can go anywhere, by express or otherwise, with perfect safety.

Premium No. 7—The Aquarius.

This is a capital instrument, valuable to have in every house. It is a portable hand force-pump, which any one can catch up at a moment's warning, and throw from a pail or other vessel a steady stream of water upon a fire in a house, or elsewhere. It is supplied with both a jet-pipe and a rose, or sprinkler, and can be used for washing windows, carriages, &c.; for sprinkling trees, plants, destroying insects, &c., &c. With it, it is easy to wash the second and third story windows, and to sprinkle water upon the roof, while standing upon the ground. Such an apparatus will often enable a person to so use a bucket or two of water as to extinguish a fire breaking out where it could not be reached with water dashed on from pails. It is supplied with suction and injection India-rubber pipes, and with air-chambers to keep up a constant stream. The weight is 8 lbs., and it can be sent anywhere as freight, or by express. We substitute this for the Hydropult, as being cheaper, and quite as good. (Price $10.) We will present an **Aquarius** complete to any one forwarding a club of 22 subscribers at $1 each, (or 27 at 80 cents each.) N.B.—Further particulars can be obtained by sending for a descriptive circular to the manufacturers, W. & B. Douglas, Middletown, Conn.

Premium No. 8—Melodeon.

125 Subscribers at $1 each, (or **237** at 80 cents each,) will entitle the person getting up the club to one of *Geo. A. Prince & Co.'s* **$75 Melodeons** (5 octaves.) These Melodeons are of very superior tone and finish. We have ourselves used one for three years past, and it has given but little trouble in addition, and is now as good as when we have heard it, as one of the very best. The different priced instruments are of equally good tone—the price varying with the size and style of finish. The size, prices, etc., of these instruments can be learned particularly, by sending a stamp to Geo. A. Prince & Co., Buffalo, N. Y., for an illustrated descriptive catalogue. The instruments given as Premiums, will be sent new directly from the factory at Buffalo, ready boxed, and without expense to the recipient, except for freight. Schools and churches will find it to their efforts and to secure one of these instruments. This has been frequently done. See "N. B," under Premium No. **10.**

Premium No. 9—Melodeon.

104 Subscribers at $1 each, (or **182** at 80 cents each) will entitle the person getting up the club to one of *Geo. A. Prince & Co.'s* **$60 Melodeons** (4½ octaves.) See No. 8 above.

Premium No. 10—Melodeon.

90 Subscribers at $1 each, (or **130** at 80 cents each,) will entitle the person getting up the club to one of *Geo. A. Prince & Co.'s* **$45 Melodeons** (4 octaves.) See remarks above. **N. B.**—Higher or lower priced Melodeons will be given for larger lists, in the same proportion.

Premium No. 11—New Cyclopedia—A Splendid and Very Valuable Work.

96 Subscribers at $1 each, (or **140** at 80 cents each,) will entitle the person getting up the club to a set of *Appleton's* **New American Cyclopedia,** now in course of publication, consisting of *sixteen large volumes* of about **770** *pages each. This is a magnificent work, forming a whole library embracing every topic of human knowledge.* Fourteen volumes are now ready, and the remaining two will be furnished as soon as issued. We recommend it to every one, whether they procure it as a premium or not. The work is sold at $3 per volume, or $48 for the set. To no better purpose could any one devote the Winter evening than in raising a club of subscribers to secure this for himself and family. Several schools have secured it, through the combined efforts of the scholars in raising clubs of subscribers. Boys have also secured it by their individual efforts.

Premium No. 12—Best Dictionary.

18 Subscribers at $1 each, (or **40** at 80 cts. each,) will entitle the person getting up the club to one of the *large Pictorial Unabridged Edition of* **Worcester's Dictionary,** (Price $7.50.) This now stands confessedly the most valuable standard dictionary published. The size of the book is **12** inches long, **10** inches wide, nearly **4** inches thick, and contains **1854 pages** of 3 columns each, giving the spelling, pronunciation, and full explanation of the terms of every word in the English Language, and as a source of general information on all subjects, stands next to the Cyclopedia. The Dictionary can be called for at our Office, or be sent by Express or otherwise, to any part of the country.

Premiums Nos. 13 to 18—Back Volumes—A First-rate Library.

These premiums (13 to 18,) will enable any one to secure the previous excellent volumes of the *American Agriculturist*, as far back as Volume XVI. We have stereotype plates and can print any number desired of the English Volumes, 16, 17, 18, 19, 20, and 21, and of the German Volumes 18, 19, 20, and 21. These will be sent in clean, new numbers, each volume by itself, with index complete, and be forwarded *postpaid.* The whole five can be taken together, or one or more copies of any particular volume be selected, as desired. They will be presented as in the table above, viz.: For **20** Subscribers at $1 each, (or 36 at 80 cents each,) we will present **six volumes.** For **16** Subscribers at $1 each, (or **30** at 80 cents each,) we will present **five volumes.**—For **13** Subscribers at $1 each, (or **25** at 80 cents each,) **four volumes.**—For **10** Subscribers at $1 each, (or **20** at 80 cents each,) **three volumes.**—For **7** Subscribers at 80 cents each, **two volumes.**—For **10** Subscribers at 80 cents each, **one volume.**—Let every one selecting these premiums be careful to name just *which* back volumes are desired.

Premium No. 19—Best File for Agriculturist.

Jacobs' Portfolio File, made just to fit the *Agriculturist*, with gilded name on back, a leather cover or portfolio, so arranged that successive numbers of the paper can be inserted in a minute, and be properly preserved in book form for reference. When one volume is complete the sheets can be removed and stitched, and a new volume inserted. A single cover will answer for a dozen successive volumes, and will last a lifetime. Has not yet made. Price is $1, and the postage 23 cents. We will forward it, postpaid, to any one sending *eleven* subscribers, at the lowest club price, (83 cents each.)

Premium No. 20—Paints.

20 Subscribers at 80 cents each, will entitle the person getting up the club to an assortment of *Windsor & Newton's* **Water Color Paints**—consisting of 12 colors, put up in a neat mahogany box, with pallettes, etc. These paints are imported from London, and are by all considered the best in the world. They are adapted to the finest work, or they will make a good and appropriate present to any of our younger readers. They will be sent post-paid any where in the United States within 3000 miles.

Premium No. 21—Paints.

15 Subscribers at 80 cents each, will entitle the person getting up the club to an Assortment of *Scott & Hodgkinson's* **Water Color Paints,** consisting of 24 colors or shades, put up in a neat case with brushes, cups, etc. These are of American manufacture, and though not so fine as the above, will answer for ordinary practice by children or beginners, and for common sketching. Sent same as No. 20.

Premiums Nos. 22 to 26.

We have not space left to describe these particularly, this month. The following list now stands as published in this journal last year. It is undoubtedly a great improvement. The Eagle Plow is well Known, and so is the Hay and Straw Cutter, and the Steel-toothed Cultivator, one of the most useful implements on the farm. The Lard and Wine Press is a very convenient household implement, for pressing out lard or tallow, the juice of grapes, currants, berries, &c. For the prices, and subscribers required, see the table above.

Reports on Crops, September 10, 1862.

(See General Remarks and Reports on Special Crops on page 296.)

SPECIAL EXPLANATIONS TO THE READER FOR SEPTEMBER. (Full details are given on the Blank Forms furnished to Reporters.)

The First Column gives the Counties from which the reports come. In many cases the territory reported upon extends over adjacent counties, and the figures apply to a larger territory than the county named, but sometimes to single townships only.

The Second Column gives the number of persons in each county or locality, the average of whose opinions are embraced in the single rows of figures, standing opposite in the same line. In several cases a whole County is represented by an officer of the Agricultural Society, who gives the summary of reports from assistants in each of the towns. ∞ indicates that a large but indefinite number of persons joined in making the report.

The Third Column gives the names of the persons who received and distributed blanks, and collected and returned the reports.

☞ *All the reports the same as a 10 unless taken as the standard for comparison*, thus :

Column A—10 means that the weather for a month previous to the date of the report was about as good as the average for other years, that is for growing crops and for general farm operations. Figures above or below **10** indicate the comparative propitiousness or unfavorableness of the weather.

Columns—B—E—in these 10 indicates that the amount of *crop harvested* is about the same as *last year*. Each figure (or unit) above **10** means a tenth more of *crop*, and each unit below **10**, means one-tenth less. Thus, **5** means one-half of average *crop*—**15** means one and a half—**20** means double, and so on.

Columns D—G—M—O—This month the figures indicate the average yield per acre in bushels.

Column H—10 indicates that the surface of corn growing is the same as in 1861.

Columns—I—S—In these **10** indicates that the surface of corn and potatoes growing is the same as the average for five years past.

Column R—10 indicates that the wants of the district are just supplied. Figures above and below indicate the surplus or deficiency.

Columns C—F—L—N—P—in these columns 10 means that the average *crop gathered* is about the same as the average for five years past. Each unit above or below **10** stands for an increase or decrease of one-tenth in the *crop*.

Columns K—T—U—V—In these columns **10** means that the *condition* and *prospect* at the date of Report, indicated an *average yield per acre*. Here also each unit above or below ten indicates the prospect of a yield a tenth above or below the average; thus, a half crop is indicated by **5**—a double crop by **20**. Some report fruit prospects at **100** to **150**, meaning that the promise is for ten to fifteen times the average.

We have carefully prepared, from our own records, and from official and other reliable sources, the foregoing series of very important tables. These indicate a remarkable increase in the Breadstuff trade of the country, which (now that Cotton has lost the supremacy) is the greatest interest of our republic, in a commercial point of view. Those tables suggest many reflections, some of which are referred to in an editorial article on page 296. They are so arranged as to make clear the wonderful prosperity of this branch of our commerce, and elaborate comment is unnecessary. The shipments of the Cereal Year closing on the 1st inst., were heavy, and in excess of any previous season. To these may be added the exports to South America, West Indies, British Provinces, etc., which for the last year amounted to 1,135,014 bbls. Flour, 158,192 bbls. Corn meal, 12,087 bushels Wheat, 502,576 bushels Corn. The importance of so good a foreign demand *at fair, remunerative prices*, with the abundant crop of the last season, can hardly be estimated, particularly in the present unsettled state of the country. We are again blessed with a good crop, and have much to spare, while European harvests are now indisputably deficient. In Flour the transactions of the month have been heavy; the supplies are moderate, particularly of that of sound quality; prices change a trifle from day to day with the value of exchange and gold, holders at the close being firm for good brands. The transactions in Wheat continue very extensive and are controlled in a great measure by the same causes that affect Flour. The late rise in English freights has checked business, and the market, up to Monday last, was much depressed, but has partially recovered within a few days, and closes with an upward tendency. Corn has arrived freely and declined in value, especially unsound and inferior lots, which constitute the bulk of the present receipts. Rye has been scarce and in demand, but closes heavily, with more offering. Oats were quite plenty and unsettled; but have been recently less abundant and in lively request at advanced prices... Cotton rapidly improved in price, Middlings reaching 59c.@60c., but the market is now dull, and quotations for Middling Uplands are down to 56c.@56½c. per lb. The receipts are increasing gradually and adding, little by little, to the available supply....The inquiry for Pork and Beef has been quite moderate; while the demand for Lard, Butter and Cheese has been active .. An unusual degree of animation has been discernable in the market for Wool, especially the coarser qualities which have advanced very rapidly, and now command much more than the finer grades, on account of the requirements of the army.. ..Tobacco, too, has been unusually brisk, and in view of the unsettled state of affairs in the West, is much dearer.....Hops are coming forward freely and are lower....The movements in other articles of domestic Produce have been fair at our quotations. The table of Prices Current, to-day, and one month previous, show present rates and the changes from our last report.

N. Y. Live Stock Markets.—THE CATTLE MARKETS have been more fully supplied during the past month than ever before, the average being 5,350 per week. The demand has been pretty active, and prices steady at ¼c. advance on former quotations up to Sept. 16th, when 6,410 cattle, the largest supply New-York has ever seen together, were thrown in for a single week and prices declined ½c.@¾c. per lb. Fears of a rebel invasion in southern Ohio, and parts of Indiana and Kentucky, caused graziers to hurry off their stock beyond the reach of danger. With such a supply, the best cattle sold at prices equivalent to 8c.@8¼c. per lb., estimated dressed weight; good steers 7c.@7½c., and poor cattle, of which there were many, at 5c.@6c., the average of all kinds being 7¼c.

Veal Calves.—Receipts have been light, averaging 489 per week. The demand improves with the approach of cold weather, and prices are ¼c. higher, or 5½c.@6c. per lb. live weight, for choice calves, 5c. for fair, and 4c. for poor grades.

Sheep and Lambs.—Receipts have been larger, averaging 13,853 per week for the past month. Prices are about the same as for the previous month, with a good demand from butchers, and an inquiry from farmers for store ewes to winter over. Good fat sheep are worth prices equivalent to 4½c. per lb., and if extra fine, 5c. per lb. live weight. Fair stock sells at 4c.@4¼c., and lambs 5c.@6c. Most of the stock sells at about $3½ per head, though some lots of heavy sheep brought $4¾.

Live Hogs have been coming forward very freely, the weekly average being 15,022. Cool weather, with a good demand for packing, has kept the stock well used up; all heavy fat hogs are selling as fast as they arrive. Prime, fat, corn-fed hogs are worth 4c.@4⅛c. per lb., live weight, and light corn-fed and still-fed are selling slowly at 3¼c.@3¾c.

The Weather has been variable, upon the whole warm and dry, though an untimely frost on Sept. 3d, injured corn, buckwheat, and the grazing lands, in some localities at the north.——OUR DAILY NOTES, condensed, read—*August* 20, 21, warm, rain wanted—22, cloudy, showers at night—23, light rain—24, 25, clear, cool—26, 27, warm, fine, shower on night of 27th—28, showers—29, 30, clear, fine—31, clear A. M., cloudy P. M., rain at night.——*September* 1, cloudy, heavy thunder shower at night—2, cool, cloudy—3 clear, cold, (44° here) frost at north—4 to 10, clear, fine Autumn weather, but getting dry—11, clear, warm, light rain at night—12, N. E. rain storm, creating a flood in some places—13, to 16, cool, and generally cloudy—17, light N. E. rain—18, 19, clear, fine days. The barometer has varied from 29.50 to 30.30 inches, which is a greater range than usual.

Thermometer at 6 A. M., New-York.

[Observations carefully made upon a standard Thermometer (Fahrenheit.)—*r* indicates rain—*s*, snow.]

The Postage on the Agriculturist is positively only Six Cents a Year.

The law expressly says that a Periodical issued at stated periods, and not weighing over 3 ounces avoirdupois, shall be charged *one cent* per number, and only *half* this sum if paid quarterly in advance. The paper for the *Agriculturist* is purposely manufactured so that it shall weigh a little *less than three ounces* when printed; the legal postage is therefore only six cents a year, if paid quarterly in advance.

Premium Strawberry Plants Sent.

All Premium Strawberry Plants called for up to this date, (Sept. 20,) have been forwarded in good order. A circular containing a chapter of directions for culture preceded each parcel, three or four days. Any failure to receive the circular and plants, if there has been any, is chargeable to irregularity of the mails.

Mail-Lost Numbers Supplied.

It is hard for the Publisher to alone bear all the losses arising from the carelessness or over-sight of any of the 18,000 Postmasters and carriers who have the handling of the *Agriculturist* between the office and the subscribers. But since Uncle Sam monopolizes the carrying business, and won't stand any losses, and we can't compel him to, we shall cheerfully send a second copy of any number when the first one mailed fails to reach its proper destination, on being notified of the fact.

Bound Volumes—Binding—Covers.

We have complete sets of Vols. 16, 17, 18, 19, and 20, both unbound, and bound separately in neat covers with gilt lettered backs. PRICES AT THE OFFICE.

Volumes 16, 17, 18, 19, and 20, *unbound*.....$1.00 each.
Volumes 16, 17, 18, 19, and 20, *bound*.....$1.50 each.

PRICES WHEN SENT POST-PAID BY MAIL.

(They can not go unpaid.)

Volumes 16, 17, 18, 19, or 20, *unbound*.....$1.12 each.
Volumes 16, 17, 18, 19, or 20, *bound*.....$2.00 each.

BINDING.—Sets of numbers brought to the office will be bound up neatly in our regular style of binding the *Agriculturist* for 50 cents a volume.

PREPARED COVERS.—Covers for binding, neatly made, with title, etc., gilt upon the back, ready for the insertion of the sheets by any bookbinder, can be furnished for Vols. 12, to 20 inclusive, at 25 cents per cover. *Covers can not go by mail.*

TO ADVERTISERS.

Circulation of the Agriculturist.

Beyond all doubt or controversy, the circulation of the American Agriculturist to regular subscribers, is many thousands greater than that of any other Agricultural or Horticultural Journal in the World, no matter what its character, or time or place of issue. The publisher is ready at all times to substantiate this statement by comparing books.

Advertisements.

Advertisements to be sure of insertion must be received at latest by the 15th of the preceding month.

TERMS—(invariably cash before insertion):

FOR THE ENGLISH EDITION ONLY.

Fifty cents per line of *space* for each insertion.
One whole column (185 lines), or more, $90 per column.
☞ Business Notices, *one hundred cents* per line of space.

FOR THE GERMAN EDITION ONLY.

Ten cents per line of *space* for each insertion.
One whole column (130 lines), or more, $30 per column.
☞ Business Notices, *twenty* cents a line.

A DESIRABLE COUNTRY RESIDENCE NEAR NEWPORT, FOR SALE.—Containing a large Dwelling, surrounded with trees, shrubbery, lawn, etc. An excellent Barn, with work shop and store rooms. A large garden, (1¼ acres,) thoroughly prepared, and supplied with fruit trees, grapes, etc. With the above, and adjoining it, is another fine plot of about 4 acres, admirably adapted for building upon, or for cutting up into smaller building lots. The two will be sold together or separately. No care or expense has been spared in fitting up the above place, and it is ready for occupation by any citizen who may not wish the trouble of preparing a place. The location is convenient to churches and good schools, and every way desirable. Accessible from the city in 30 minutes, nearly every hour during the day. About $6,000 or $7,000 cash will be required; the rest can remain on mortgage if desired. For further particulars address Z. Box 189, N. Y. Times office.

OUR "EXCELSIOR BURR STONE MILLS,"
AND
ANTI-FRICTION
HORSE POWERS.

HAVE taken the HIGHEST PREMIUMS WHEREVER EXHIBITED! NINE FIRST PREMIUMS being received from WESTERN STATE FAIRS last year.

THE MILL may be driven by *horse, water,* or *steam power,* does its work equally as well as the best flat stone mills in milling establishments, and requires but *one-half the power* to do the same amount of work. They are made in the best manner, and will last *thirty years,* and *cost nothing for repairs.*

THE HORSE-POWER runs upon iron balls, and requires but TWO AND A HALF POUNDS DRAUGHT to keep it in motion. With the same number of horses it will do TWENTY-FIVE PER CENT more work than ANY OTHER POWER IN USE.

Price of Power for 1, 2, 3, or 4 horses.....$125
Price of Power for 1 to 8 horses.....150

The $125 POWER WILL DRIVE ANY THRESHING MACHINE, and was awarded the first premiums over the BEST 8 AND 10 HORSE POWERS at the State Fairs last Fall.

☞ EVERY MACHINE IS GUARANTEED TO GIVE SATISFACTION, OR THE MONEY WILL BE REFUNDED.☜

J. M. THORBURN & CO.'S
Autumn Catalogue
OF
Imported Dutch Bulbous Roots,

With directions for their culture and management, is ready for gratuitous distribution.
Our splendid assortment of Bulbs this year will be found particularly worthy of notice. Those of our friends who are only acquainted with the few varieties that were usually supplied from European collections, in times past, should at once send for our fifth Catalogue; they can form no idea of the improvements that have recently been made in all the various sorts.

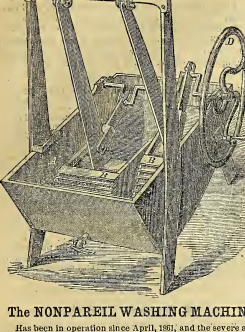
PRINCE & CO., Flushing, N. Y



The NONPAREIL WASHING MACHINE

Has been in operation since April, 1861, and the severe and varied tests, to which it has been subjected, in country and city families and laundries, demonstrate that two-thirds the labor and time, and half the soap required in hand washing, are saved by its use, and no injury can possibly result to the most delicate fabric from its action. It is a squeezing machine, and it washes with equal effectiveness a cambric handkerchief, or a bed quilt.

The machine is carefully made of the best materials, and its strength and durability will be found in keeping with its extreme simplicity. There is nothing in its construction liable to get out of order; and no training is required to enable the least skillful person to work it satisfactorily. A girl twelve years old can operate it.

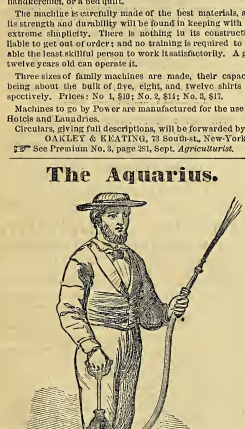
Three sizes of family machines are made, their capacity being about the bulk of five, eight, and twelve shirts respectively. Prices: No 1, $10; No. 2, $14; No. 3, $17.

Machines to go by Power are manufactured for the use of Hotels and Laundries.

Circulars, giving full descriptions, will be forwarded by OAKLEY & KEATING, 73 South-st., New-York.

☞ See Premium No. 5, page 281, Sept. *Agriculturist*.

The Aquarius.



A HAND FORCE-PUMP.

GROVER & BAKER'S CELEBRATED NOISELESS SEWING MACHINES.

Acknowledged to be Superior to all Others,

495 *BROADWAY, NEW-YORK.*

"Grover & Baker's is the best."—*Am. Agriculturist.*

FOR SEWING MACHINES.

JONAS BROOK & BROTHERS' PRIZE MEDAL SPOOL COTTON,

WHITE, BLACK, AND COLORED.

200 or **500** yard spools.

For MACHINES, use BROOK'S PATENT GLACE for upper thread, and BROOK'S SIX CORD BEST TICKET for under thread. Sold by all first class dealers in city and country; also in cases of 100 dozen each, assorted numbers, by WM. HENRY SMITH, Sole Agent, 36 Vesey-st., New-York.

MRS. WINSLOW,

AN EXPERIENCED NURSE and Female Physician, presents to the attention of Mothers her

SOOTHING SYRUP

FOR

CHILDREN,

which greatly facilitates the process of Teething, by softening the gums, reducing all inflammation—will allay ALL PAIN and spasmodic action, and is

Sure to Regulate the Bowels.

Depend upon it, mothers, it will give rest to yourselves, and

Relief and Health to your Infants.

It not only relieves the child from pain, but invigorates the stomach and bowels, corrects acidity, and gives tone and energy to the whole system. It will almost instantly relieve

Griping in the Bowels and Wind Colic,

and overcome Convulsions, which, if not speedily remedied, end in death. We believe it the BEST and SUREST REMEDY IN THE WORLD, in all cases of DYSENTERY and DIARRHŒA in children, whether it arises from Teething or from any other cause. We would say to every mother who has a child suffering from any of the foregoing complaints—DO NOT LET YOUR PREJUDICE, NOR THE PREJUDICES OF OTHERS, stand between you and your suffering child and the relief that will be SURE—yes, ABSOLUTELY SURE—to follow the use of this medicine, if timely used. Full directions for using will accompany each bottle. None genuine unless the fac-simile of CURTIS & PERKINS, New-York, is on the outside wrapper.

Sold by Druggists throughout the world.

Principal Office, 13 Cedar-Street, New-York.

Price only 25 cents per bottle.

Pyle's O. K Soap.

The best ever invented for household use. No other soap is required, either for the Laundry or Toilet, where **Pyle's O. K.** is used. The most intelligent classes approve it. The Editors of this Paper, and of all the religious papers, and of the Tribune and Evening Post patronize it. Every housekeeper should ask the Grocer for **Pyle's O. K. Soap and Saleratus,** if they want the best goods made.

JAMES PYLE, Manufacturer,

N. B.

Every new Subscriber for 1863 received now, or before October 31st, will be presented with the Agriculturist for November and December without charge.

The above includes **all** new Subscribers, whether coming single, or in premium clubs, or for maps, or from Agricultural Societies, or otherwise. *All* new names are now entered from the date of reception to the end of the next volume, (December 1863.) This now gives 14 months for the price of 12, that is, **'BAKER'S DOZEN.'**

Wanted by Everybody Just Now.

And can now be obtained without extra charge by Every One Subscribing to the American Agriculturist.

A very large, comprehensive, and very complete

Map of Virginia,

(Including Maryland, and part of Pennsylvania.)

Giving every River, Small Stream, Mountain, City, Town, Village, and the Principal Roads, Mountain Passes, etc., etc., of the whole State of VIRGINIA, East, West, North and South. ALSO on the same Map the principal Rivers, Cities, and larger Towns of the whole of **Maryland**, and the greater part of **Pennsylvania**, thus furnishing a complete guide to the location and operations of the Armies in the East—Lloyd's Great Map is the largest and most complete one now published. It covers a surface of *more than* **ten square feet.** It is beautifully colored in counties. By a new process of printing, it is worked off very rapidly, and so cheaply as to be within the reach of every family.

SEE HERE!—*When desired, a perfect copy of the above Map will be mailed free (with postage pre-paid), for* EACH *new subscriber sent in for the American Agriculturist during October, at the regular price of $1 a year. (New subscribers for 1863 also receive November and December of this year free.)*

☞ The Map is designed as a premium for new Subscribers. Any present Subscriber sending in one or more new names for the map, may also receive a copy of it for himself, by renewing his own subscription at the same time at $1 a year.

OR, INSTEAD OF THE ABOVE,

A large Map of **all the Southern States,** including Missouri, Kentucky, Virginia, Maryland, Delaware, and all South of them. The States are Colored, and the Counties all Indicated, together with the towns, rivers, etc. This Map is 3¼ by 4½ feet, and contains about **15** square feet of surface. It is specially valuable at this time.

FOR **Two** SUBSCRIBERS AT $1 EACH.

We will send (post-paid,) Lloyd's great MAP of all the

United States, Canadas & New Brunswick,

(with every County colored separately.)

This is a splendid, large Map, 3¼ by 4½ feet, or nearly **15** square feet of surface. It is very valuable at any time, and especially now, when every one is daily studying the geography of our country. ☞ These Maps of course exclude all other premiums on the *same name*, and are as yet *only* offered for October, except to such persons as live too distant to respond within the month.

Pumpkins, Squashes, and Ornamental Gourds.

There will be a **Public Exhibition** of PUMPKINS, SQUASHES, AND ORNAMENTAL GOURDS, at the office of the *American Agriculturist*, 41 Park Row, New York City, opening on Wednesday, **Nov. 5th, 1862,** at which the following prizes will be paid by the Publisher, upon the official award of competent Committees.

CASH PREMIUMS.

No. 1—For the *Heaviest* Pumpkin or Squash...			$20.00
No. 2—For the 2nd	do.	do.....	10.00
No. 3—For the 3d	do.	do.....	5.00
No. 4—For the Best	do.	do. for cooking.	10.00
No. 5—For the 2nd Best	do.	do.	5.00
No. 6—For the largest yield on a single Vine...			10.00
No. 7—For the 2nd	do.	do.	5.00
No. 8—For the largest and finest collection of Fancy or Ornamental Gourds*...			10.00
No. 9—For the 2nd	do.	do.	5.00

* All to be grown by one person and to be accompanied by an affirmed statement from the grower, and two disinterested persons who assist in gathering the specimens.

Note 1.—The specimens receiving the Prizes will remain on Public Exhibition at the pleasure of the Publisher who offers the prizes. The other specimens will be subject to the order of the exhibitors, or they will be sold at Auction if not otherwise disposed of, for their benefit.

* *Note* 2.—All Exhibitors must notify us of their intentions by Oct. 10th, and deliver specimens for competition on or before Nov. 3d. Specimens to be delivered free of charge.

A Constant Exhibition.

The Tables at the Office of the *American Agriculturist* have constantly during the entire year novel and interesting FRUITS, FLOWERS, GRAINS, VEGETABLES, ROOTS, ETC., contributed by SUBSCRIBERS, NURSERYMEN, GARDENERS and others, and almost uniformly present a very attractive and instructive exhibition. The daily show of fruits and flowers is now large and interesting. While we are most happy to receive contributions to our *Exhibition Tables Every Day*, we specially invite THURSDAY OF EACH WEEK as a convenient day for a special show of FRUITS during this and the following two or three months; on which days we shall be especially happy to see any of our friends, who are at all times most welcome. See p. 292.

Our tables are regularly visited by an Office large and early, and the best care will be taken of the articles contributed.

American Agriculturist in German.

THE AMERICAN AGRICULTURIST is published in both the English and German Languages. The Editions are of the same size, and contain, as nearly as possible, the same Articles and Illustrations. The German Edition is furnished at the same rates as the English, singly or in clubs. A club may be part English, and part German.

American Agriculturist.

For the Farm, Garden, and Household.

A THOROUGH-GOING, RELIABLE, and PRACTICAL Journal, devoted to the different departments of SOIL CULTURE—such as growing FIELD CROPS; ORCHARD and GARDEN FRUITS; GARDEN VEGETABLES and FLOWERS; TREES, PLANTS, and FLOWERS for the LAWN or YARD; care of DOMESTIC ANIMALS, &c., &c., and HOUSEHOLD LABORS. It has also an interesting and instructive department for CHILDREN and YOUTH, alone worth the cost of the paper.

A full CALENDAR OF OPERATIONS every month.

THREE to FOUR HUNDRED, or more, illustrative ENGRAVINGS appear in each volume.

Over TWELVE HUNDRED plain, PRACTICAL, instructive articles and useful items, are given every year.

The Editors and Contributors are all PRACTICAL WORKING MEN.

The teachings of the AGRICULTURIST *are confined to no State or Territory, but are adapted to the wants of all sections of the country—it is, as its name indicates, for the whole* AMERICAN CONTINENT.

TERMS—INVARIABLY IN ADVANCE,
(For either the English or German Edition.)

One copy, one year.....$1 00
Six copies, one year.....5 00
Ten or more copies one year.....80 cents each.

☞ Add to the above rates: Postage to Canada, 6 cents; to England and France, 24 cents; to Germany, 36 cents.

Postage anywhere in the United States and Territories must be paid by the subscriber, and is *only six cents a year*, if paid in advance at the office where received.

All business and other communications should be addressed to the Editor and Proprietor,

ORANGE JUDD, 41 Park-Row, New York City.

FROM THE STEAM PRESSES OF JOHN A. GRAY.

AMERICAN AGRICULTURIST,

FOR THE

Farm, Garden, and Household.

"AGRICULTURE IS THE MOST HEALTHFUL, MOST USEFUL, AND MOST NOBLE EMPLOYMENT OF MAN."—WASHINGTON.

ORANGE JUDD, A.M., EDITOR AND PROPRIETOR. Office, 41 Park Row, (Times Buildings.)

ESTABLISHED IN 1842. Published both in English and German.

$1.00 PER ANNUM, IN ADVANCE. SINGLE NUMBER, 10 CENTS. For Contents, Terms, etc., see page 352.

VOLUME XXI—No. 11. NEW-YORK, NOVEMBER, 1862. NEW SERIES—No. 190.

Entered according to act of Congress in the year 1862, by ORANGE JUDD, in the Clerk's Office of the District Court of the United States for the Southern District of New-York. ☞ Other Journals are invited to copy desirable articles freely, if each article be credited to *American Agriculturist.*

☞ See pages 346, 349 and 353, this month.

November.

"These rules consider well, with early care
The vineyard destined for the vines prepare;
But long before the planting, dig the ground
With furrows deep, that cast a rising mound:
The clods exposed to winter winds will bake;
For putrid earth will best in vineyards take,
And hoary frosts, after the painful toil
Of delving winds, will rot the mellow soil."—VIRGIL.

There are many indications now of rapid progress in vine culture in this country. Until the present generation, the supposition has been general among all, who have bestowed a thought upon the subject, that there was something peculiar in our climate that forbade the successful cultivation of the finer varieties of grapes. Grapes that flourish in southern Europe, here needed the protection of glass to bring good clusters. In the open air they were, almost with out exception, sad failures. The cultivation of the vine goes hand in hand with a high civilization, and it is not until a people have done their pioneer work, and begin to demand luxuries, that they will be likely to succeed with the vine, whatever their soil and climate. There will be little demand for the products of the vine; and the requisite skill to manage vines, and to manufacture wine, will not be called forth. Our position hitherto has been that of a pioneer people. For two centuries we have been getting ready to live, rather than living. Our work has been the leveling of forests, the opening of farms, the building of bridges, roads, railways, ships and steamers. Our luxuries have come mainly from abroad. We have furnished the raw material—wool, hemp, cotton—and other nations have manufactured for us. We have been so intent upon the necessities of life, that we have overlooked its comforts and luxuries. We have, as a general thing, been content with the rudest and most unskilled labor, adequate only to produce coarse fare and coarse clothing.

It requires much more care and knowledge to manage a vine than a cane or cotton plant. It must have skill in its planting, in directing its growth, in thinning and harvesting the clusters, in marketing them or in making wine. It indicates a new era in a nation's history when they become vine growers. Their golden age approaches, when every man "sits under his own vine." Wild vines have always flourished upon our soil, and to an uneducated taste they are a tolerable fruit. But almost every one, after eating well ripened Catawbas, or, better still, Delawares, pronounces the wild fruit worthless. Even if the fruit were better, there are serious objections to cultivating the wild vines. They are not very productive, the berries fall early from the stem, and they do not improve by cultivation. Since the introduction of new varieties which ripen as early as the wild natives, there is nothing to be said in favor of the latter.

The Isabella and the Catawba were the pioneers among the improved varieties, and have done a great and good work in educating the taste of the people, and starting amateurs upon a career of improvement. The Diana followed, a seedling of the Catawba, an earlier and a much better grape. This has not yet been before the public twenty years. When well grown it leaves little to be desired in all the qualities of a good grape. It abounds in a fine, rich juice, vinous and aromatic, from which all the offensive native odor has disappeared. It hangs upon the vines for a long time, is not injured by frosts after it is ripe, and keeps well for winter use. It is said to make good raisins, but how extensive the experiments were upon which this opinion is founded, we are not well informed. It is exceedingly productive and very vigorous.

Within the last five years the candidates for popular favor have multiplied exceedingly, and at the exhibitions of our horticultural fairs the grapes are crowding in more and more every year. The latest and best information upon the merits of these new grapes is embodied in the reports of the American Pomological Society, especially in the reports of the State and district committees. In a compilation of these reports recently published under the auspices of the Society, it appears that the Catawba does well in twelve of the 35 districts into which the northern fruit-growing belt is divided. This belt embraces all north of the southern line of Virginia, Tennessee, and Missouri, east of the Rocky Mountains. The Concord flourishes in twenty of these districts. The Delaware in nineteen, the Isabella in fourteen, the Hartford Prolific in ten, the Clinton in nine, the Rebecca in eight, and the Diana in eighteen. It would not perhaps be fair to infer that these grapes are failures in the rest of the districts, except in the case of the Isabella and the Catawba. These have been long enough before the public for a fair trial, and it is well known that the season is too short for them north of the southern line of Massachusetts. Some of the most promising grapes are yet in the hands of amateurs, and it is quite possible that these will throw every thing we now have into the shade. We saw clusters at the recent meeting of the Pomological Society that would have done credit to hot-house cultivation; they certainly surpassed all we ever expected to see of hardy grapes, grown in this country. We think fruit-growers have every reason to persevere in their efforts to hybridize, and to originate new sorts better adapted to our climate, to plant vineyards, and to make grapes the fruit of the million. The last census throws some light upon the progress which vine culture is making among us. The increase of our population in the last decade is shown to be thirty-five per cent.; the increase of the products of the orchard, one hundred and sixty per cent.; increase of wine, seven hundred and fifty per cent. This increase is doubtless largest in the valley of the Ohio, stimulated by the example of Longworth, and his fellow laborers; but in almost every northern State attention is turned in this direction, and small vineyards are planted and made profitable. Our population is so large and the price of grapes is so high in our cities and villages, that little has yet been done at wine making, beyond the domestic manufacture. The products of the vine in this region, will be likely to be marketed in the shape of fruit for many years to come. Grapes at ten cents a pound can not be made into wine economically.

We do not apprehend the peril to the cause of temperance from vine culture which some very honestly cherish. Nor do we believe, with others, that the making of pure wine from our own prolific vineyards will have any tendency to abate the evils of drunkenness. The cure of that evil lies a little further back than the scarcity or abundance of intoxicating drinks, or the higher or lower grade of alcohol in them. The young slide into drinking habits from the want of proper food and moral influences at home. The food is coarse and heating, and without much variety. The home is without refinement and without attractions. The boy has a restless craving for what he does not find at home, seeks society, and finds bad company and advisers in places of vicious resort. A strong temptation is removed when the young have variety and the luxury of delicious fruits, intelligent society and happiness under the parental roof. We want vines for our homes, for ornament and for fruit, and it will be scores of years, with the best labors of all our amateurs and nurserymen, before good grapes in their season will be common upon the tables of all classes. Let us plant vines in larger numbers, not doubting that He who gives the clusters will give us and our children wisdom to use them rightly.

Calendar of Operations for Nov., 1862.

SUNDRY HINTS FOR THE SEASON.

Farm.

In these exciting times, and with the general deficiency of good help, that man must be a good calculator, and fortunate withal, who has been able to get his work all up with the season, so as to be ready now to calmly await the approach of winter. Most persons will doubtless find it necessary to attend to many suggestions given in the Calendar in the October *American Agriculturist*. This done, there are yet the late turnips and carrots to be gathered and stored—perhaps potatoes to be dug, corn to be husked, grain to be threshed and marketed, cattle, hogs, and poultry to be fattened, sorghum to be manufactured, leaves to be gathered in abundance for the hog pens and manure heap before they are covered by snow, fire wood to be provided, buildings to be repaired, etc., etc. Then timber should be got in seasoning for tool handles to be made during winter; and there is fencing, draining, subsoiling, and trenching or throwing up the soil in ridges to expose it to Winter's frosts.

Animals—Keep them always improving; twice or thrice as much food and time are required to bring up an animal fallen off in flesh, as will be needed to keep them in good condition; a single exposure to a cold storm is as likely to involve influenza, and general debility in a farm animal, as in the owner himself. Comfort for the animal is money in the purse of the proprietor.

Barns and Stables—Stop the rain leaks in the roof, and the cold air leaks around the stalls. That clapboard is loose or gone. That great crack under the door lets in cold, and the horse or cow must have more fuel (food) for the fire within the body to counteract the cold draft without. Pure air is essential, but let it not come in chilling currents upon man or beast. With ventilators above for the escape of bad air, there will generally be enough good air stealing in almost insensibly through the seams and crevices; if not, admit it from some point where it will not blow directly upon any human or other animal. Light is as essential to animals as to vegetables; potato vines in the dark cellar are no more bleached and injured than the animal kept in a dark stable.

Butter—Owing to the dry weather, butter will continue to command a good price *if* of fair quality and well put up. Cleanliness and thorough working out the buttermilk are the first requisites. To secure good butter, the churning should be at the temperature of 55° to 60° Fahrenheit. Bring the cream to this condition by letting it stand for sometime in a room just at this heat; or make it warmer or colder by setting the churn, or other vessel holding the cream, into warm or cold water as needed.

Cellars—Many a family has been made sick by effluvia from the cellar; the feild air from decaying vegetables, is as bad as the malaria from a swamp. Through draining, ventilation, and plenty of lime whitewash, are good, both for the things kept in the cellar, and for those living above it. A little hydraulic lime mortar, with bits of stone, are good stoppers for rat and mice holes. Just above freezing is the best cellar temperature for fruits, cabbages, and indeed for all things to be kept therein, except sweet potatoes, which need to be in the warmest, dryest part, but not in a hot place. Common potatoes endure rather more warmth than apples and other fruits; these must be kept cool. Sashes with double glass and an intervening thin space of confined air, are nearly equal to stone walls in shutting out cold. Protect the exposed walls with a bank of earth outside, or what is neater and better, spent tanbark if it be accessible.

Cisterns—Pure clean rain water is better for man and beast than any well or spring water medicated with lime and other salines dissolved out from the soil. If not already done, empty and clean foul cisterns now, when rains may be depended upon to fill them again. (See note on examining cisterns and wells, elsewhere.)

Corn—Dampness and frost combined, injure it for food, and especially for seed. Much of the corn brought to this market is sold as "unsound." The sooner it can be husked and placed in a dry room the better. The crib should never be more than 3 or 4 feet wide, and let plenty of air holes be left, by slats at the bottom and the sides. *The roof should project far over the eaves*, to prevent storms beating in upon the sides. A little cat terrier dog chained under or in the corn house is the best rat-trap we know of. If the crib be set on posts covered with tin or wide projecting tin or sheet iron caps placed on top of the posts, rats and mice will find it hard work to get in. Seed corn should have been selected from the earliest and most productive hills, husked, and kept dry. If not done, immediately select the best yet available. A shilling's care now may save the loss of an acre next season. Nice corn husks, torn in shreds, make excellent filling for beds.

Cotton—Begin picking before the seeds are fully ripe. Rain storms injure the fiber after it is matured. Some sunning is needed for that gathered early. (See basket.)

Draining—This pays, in the field, in the garden, and *around* the barn-yard to keep out washing water. A drain or two under the garden will advance the working a week or two in Spring, and make the product much better, by letting in warm air and preventing the chill produced by the evaporation of the water from the surface during Summer. The same results are produced in the field. No one who drains an acre and notes the results, will fail to drain other acres afterwards. It pays on almost all soils, even those usually considered dry. Try a little draining this month, and if it don't pay charge the result to our account—crediting us with the good done, of course. Remove the standing water, by an under-drain, from that sickly tree, and it will smile upon you with its load of blushing fruit. Run out this morning, and clear the obstructions from the dead-furrow drains in the winter grain. Frost will not kill wheat or rye; frozen water in the soil will; water in freezing expands one eighth of its bulk, and rears and heaves the roots; perfectly dry soil expands none in freezing; moist soil expands but little.

Fruit—Though plenty this year, it will pay for carefully saving. (See Fruit for Soldiers, elsewhere.) Apples should be kept as cool as possible without being touched by all by frost. Sort frequently, handling with care; one bruise rots the apple, and the disease spreads rapidly to others. Apples packed in *dry* oats, or bran, or cut straw, or leaves, and kept cool, will remain sound long after their usual time of decay.

Fuel—It takes the heat of almost one half of green or soggy wood to burn up the other half. Water in changing to vapor absorbs and conceals a thousand degrees of heat. A cord of charcoal gives out more heat in burning, than a cord of wood. A cord of thoroughly dry wood loses a thousand times less heat in the smoky vapor, than if burned when green. Therefore, get the Winter's fuel to drying out, under cover, as soon as possible. It will save fuel, time, vexation, and health, and be a mercy to the housewife.

Grain usually keeps better in the bin than in the mow or stack, especially where mice abound, and in the bin it is ever ready for market when the "signs come right." The straw can then be turned to account for feeding and bedding. Do not burn it, even in the new rich prairie regions. Let the cattle nest on it. If it can not be used, let it lie even five or ten years; there will in that time surely be some place that will be benefited by an application of well rotted vegetable matter. Clean the grain for market well. A bushel of chaff, fowl stuff, or shrunk grain in 100 bushels, will lower the price of the whole 3 to 10 cents per bushel—an important difference, and one which must pay for an extra fanning and screening. "Like produces its like." so save the best and plumpest kernels for seed. We *know* this pays by not a little experience of our own, and by that of many others.

Hedges—Thorns and other deciduous hedge plants may be set until the ground freezes.—Leave evergreens until next May.

Hogs—They fatten most on the same food when the weather is warm. The heat of all animals is sustained by the internal burning (oxydization) of the fat-producing elements. As soon as the fire goes out (in death) the flesh becomes cold. In cold weather 20 to 90 per cent. of the food, and often the whole of it, goes to keeping up the animal heat. As cold comes on, give the hogs a warm pen, or a warm nest of straw, and see them lay on fat. Increase their bulk by feeding the coarse food first, and then finish off by filling up the tissues with fat furnished abundantly by corn. For early pigs, turn in the males now. Sows run about 4 months, (109 to 123 days.)

Horses, next to man, need clean, well ventilated, well lighted quarters. The curry-comb and dry brush do more than make them look well; a clean skin promotes health. It is cruel, and bad economy, to drive a horse until he sweats, and then let him stand five minutes with a half blanket across the middle of the back. The cover should go well over the shoulders and hips, and down far enough to ward off currents of cold air from the thighs, belly, and shoulders. See page 330.

Implements—The thrifty man will not only *know* where they are, but see that they are never exposed to rusting or rotting by dews and rains. As a rule, tools are destroyed more by exposure than by use. A hint to the readers to thinking on the subject is all we have room for here. See page 335.

Ice Houses—See hints on page 297, in October *Agriculturist*. The first crop of good ice may be the only one, and should be secured.

In-Door—Does *your* wife blister her fingers trying to cut cloth with dull, loose-riveted sheers or scissors? A hammer for the rivet, and a whetstone or grindstone, or a file will brighten the edge and wife's or daughter's countenance at the same time. Then, there are the dull knives; how much arm work and vexation they make in haggling meat. Desert the talking regiment at the store or post-office some night, and fix up the housekeeping tools; do it often, and your rations will be dealt out more regularly, and in better shape. Finely cut hash (meat and potatoes) is a good, wholesome food, particularly for those who have sore teeth; but it is hard work to cut it fine with a dull chopping knife. Keep that tool sharp. Hale's meat cutter is cheap ($2½ to $4) and will cut more hash or sausage meat, in five minutes, than you can cut with knife and chopping bowl in fifty minutes, and do the work better. It will cut the meat and potatoes together.——Do you want an intelligent wife and children? Then let them read the papers, and talk *with them* about the news of the day.——The brain should be hard at work farming, while king Jack Frost has the hands tied. Study the agricultural papers and books, instead of merely reading them. In studying over a hundred pages you will be likely to hit upon a hint or two, or get a thought started that will result in a hundred dollars profit. The only money we have ever made in farming, gardening, or publishing, has resulted from plans laid while sitting in the dark, or lying in bed *thinking*. Hard work without thought may keep you from starvation; hard work with well digested plans may yield a competence. Get from books and papers all of other men's thoughts you can; it won't improve them, while enriching you.

Leaves from the Forest—Every one knows the value of black soil from the forest for fruit trees, and for the garden generally. It is equally good for field crops. This material is only the decayed leaves mixed with a little of the surface soil. It will pay to collect all the leaves accessible, for the manure heap, for the hog pen, and for the horse and cow stall. Here they will finish a good fertilizing material; or they will be a good mulch (both protection and manure) if spread on the soil around fruit trees; in the forest they may take fire and destroy much valuable timber.

Manures—A gill of foul water from the barnyard, or a handful of manure (animal droppings, decayed straw, leaves or muck) put into a hill will produce at least one more good ear of corn; a hundred gills of the liquid, or a hundred handfulls of the manure, will produce a hundred ears. How about a hundred bushels more? Every possible shovelful of manure that can be collected or made anywhere on the premises, should be cared for. Let the imagination dwell upon a mountain of good manure next Spring, and fancy the results it will yield; then make a business this Winter, beginning to-day, of increasing the mountain to the largest possible size, and having it of the best possible quality. Gather up the fragments; see to it that not an ounce of vegetable or animal matter be permitted to waste its gases in the air, nor a gill of brown liquid to run to waste from the yard or stables, or privy. It pays to save it all to be placed in the soil to nourish growing plants.

Plowing in Autumn is highly beneficial. The new soil turned up (and some should be every year), is ameliorated by frosts. The herbage turned under is saved; on the surface much of it would be lost in decay, or washed away by rain and melting snows. Soils plowed now are dry and warm at an earlier day in Spring and ready to plant or sow sooner. Plow up now every acre possible.

Potatoes—See page 333. Warmth with moisture are injurious, next to actual freezing. Dryness, and a cool but not freezing atmosphere, in the cellar or earth-covered heap, are essentials. When in out-door heaps, dig a deep trench around it with its mouth to the south, so that the bottom of the heap always dry. Add more earth to the heap only as needed by the increasing cold, always spatting down each layer of earth smoothly to shed rain.

Poultry, welt cared for, pay by the meat, the eggs, and the home-made guano they produce. The secret of having eggs all the winter is to give the hens the advantages of Summer, viz.: warm shelter, light, water, and some animal food to supply the absence of insects which they gather in Summer, with lime enough to make egg shells. They devour and grind up the weed seeds among the grain tailings fed to them; they eat almost every kind of grain; the bones and scraps of *fresh* meat they devour greedily and convert them into eggs. A cake of scraps from the fat-trying establishments, costing hardly a cent a pound, thrown into the yard or where they can get at it, will supply good, cheap, animal food. They will peck at and devour it until the last bit is consumed. Give them also the cabbage leaves, potato parings and other refuse vegetables. See page 268, September *Agriculturist*.

Pumpkins—Avoid bruises in handling; store in a cool dry place, always free from frost; remove seeds when fed; dry as directed last month.

Schools—A well disciplined mind, stored with knowledge, is a better fortune for your children than broad acres, or a mint of money. With the former, they will be able to take good care of themselves; without, the property inheritance will be of little value. Secure good teachers; always speak respectfully of them, or your children will

not; don't send the children from comfortable homes to a poorly heated, badly ventilated, homely barn on the road side—called a "school-house"—if your effort can improve the building and its arrangements. You would not put a colt out to pasture for a season without inquiring after it, and going often to see how it prospered; would you send a child to the care of another, and never go to see how it fared, and manifest no special interest in its progress and mental growth. Three or four hours of close mental application is all the young child can endure at home and in school, without sacrificing the growth and health of the body; an active mind in a poor sickly body is of little account. A cheap teacher, one who will accept low wages because not smart enough to do any thing else, is bad economy. Many spend $20 to $50 dollars in clothing and getting a scholar to school, but lose half the benefit by scrimping a shilling in the purchase of suitable books. Let every child daily practise drawing, with pencil and paper or slate; it disciplines the eye and taste, makes him a better observer, and developes mechanical taste and skill, which are great helpers in any occupation, especially that of the farmer. See "Handy Farmers," page 335.

Sheep are now, and are likely to be, the most profitable branch of farming. (See page 330.) Give them all needed attention in shelter and feed. When kept at an open stack, or exposed to storms, they eat more (to keep out the cold), but thrive less, and suffer more from disease and or colds, manifested by running at the nose. Turn in the buck this month for April lambs. Later lambs, dropped when the grass is well started in May, generally come out ahead in Autumn. Early lambs pay well near cities.

Sorghum is an important crop, in these high-priced sugar days. See page 332.

Turnips will come in good play this Winter, especially where the hay crop is short this year. Leave them growing as long as it is safe to do so. If caught by frost, cover them with soil before they thaw in the least, and gather when the frost is out. Pull and cut off the tops. If dry and warm, let them lie on the ground until towards evening to dry the adhering soil. They can be stored in a dry cellar, or in heaps covered with straw and soil, pointed up and smoothed with the shovel back to shed rain. They keep better if allowed to sweat and dry for a few days in open heaps.

Weeds—Gather carefully and burn, or compost in a heap of vegetable manure to destroy their vegetating power.

Winter Grain—It is bad policy to feed off the thick growth in Autumn; let it remain as a Winter protection and Spring mulch. Look after the standing water. See suggestions on draining, preceding page.

Orchard and Nursery.

Important work is to be done both in the Orchard and Nursery, between now and settled Winter weather. In Autumn, as soon as the leaves begin to fall, is the best time of the year for transplanting hardy fruit trees and small fruits, and no investment yields better returns in the long run, when the trees are judiciously selected and properly cared for. Transplanting, manuring, pruning to promote growth, and root-pruning to induce fruitfulness, labeling and staking trees, banking around their trunks to keep mice away, gathering late varieties, and marketing or storing, destroying insects, making cider, and drying fruit, will constitute the main work of the orchardist. The nurseryman will have trees to take up, pack, and market; young seedlings or stocks to graft or "heel in" (or store in the cellar), for grafting in Winter; cuttings, cions, and layers to gather, furrows to turn against young nursery rows, seeds and pits to procure, labels to provide, etc.

Cider—Use good, ripe fruit for the best cider, and poor fruit and pomace washings for common vinegar, p. 336.

Compost—For light soils, with each cord or 100 bushels of mud, muck, peat or heavy loam, mix 10 bushels wood-ashes, 20 or 30 bushels fresh manure, half-a-bushel of salt and a peck of plaster, together with all the decaying vegetable refuse available; for heavy soils, use sand and light loam to cold and heavy loam.

Dry apples for market, for use and for the soldiers.

Pruning is better done now than in Spring, but best in mid-summer. Trees to be transplanted should be pruned in proportion to the curtailment of roots in taking up. Have a sharp knife and make smooth, slanting cuts. Root-pruning may be advantageous to induce fruitfulness. Cut off the tap root, so that the lateral roots will push vigorously early in Spring. Cut with a sharp spade.

Fruit—Spread out on shelves or on the floor to guard against dampness and mustiness. Keep all fruits dry, and as cool as may be without danger of freezing. For transportation pack apples in clean barrels with *dry* oats, chaff, bran, or forest leaves.

Frosted Trees—Cover at once with dryish, light soil, so that the frost may be extracted gradually.

Grapes—Hardy vines may be planted now. Be sure to get the best *proved* varieties, as they require neither more room nor time than those which will yield less valuable, less profitable fruit. Give them rich soil well worked to the depth of three or four feet, with a generous admixture of rotten wood, leaves or sawdust, scraps of old leather, crushed bones, etc., and a southern exposure, protected from heavy winds and early morning sun. Set them a little deeper than they grew, and pack mellow soil firmly around their roots, allowing no fresh manure to come in direct contact with them. Prune out all secondary shoots, and cut back the main stem to two good eyes or buds. Protect old vines by bending them down and covering lightly with earth. Make hillocks about eighteen inches high around young vines, with dirt brought from beyond the area of their roots. As the remaining tops should be pruned away in Spring, no harm will be done if they winter-kill, unless wanted for cuttings, in which case bury them as directed for older vines.

Insects—Destroy borers, bark-lice, worm nests, etc. One killed now saves killing thousands next year.

Label or map every tree, so that the name and nature of its fruit may be readily ascertained. Strips of sheet zinc written on with a sharp awl make very good labels.

Manuring in Fall stands approved. It protects the roots of trees during Winter and nourishes them thereafter. Apply well rotted stable manure, or leaf mold, lime, coal ashes, etc. Pears especially appreciate very liberal manuring. Peach trees may be surfeited, and should be manured sparingly, according to the richness of the soil. Soap suds and urine are excellent for grape vines, pear and apple trees in grass plots, currant bushes, etc.

Packing Trees for Transportation.—The roots should be well filled in with damp moss, if it can be obtained. Thorough puddling in mud will answer for short distances. Bundles to go far should have a stout, straight stick placed in the center, packing the trees around it. Bind on long straw outside the bundles, roots and all.

Staking—Set two strong stakes opposite each other and parallel with the body of the tree a few inches distant and about four feet high, then fasten one end of a firm band of straw or listing on the top of each stake, pass each band around the trunk of the tree and back to the same stake, and fasten it. Thus the tree will be held from both directions without rubbing against either stake.

Taking up Trees—The small roots are the mouths of the tree. If broken off, the tree is put back at least until more rootlets are formed. Buy no trees with badly mutilated rootlets, if it can be helped.

Transplanting—Do not thrust trees into "by 9" holes, like stakes and fence posts, if you want them to pay well. Dig up broadly and deeply, as this can only be done once in the lifetime of the trees. The better this is done the longer will the tree flourish and bring forth fruit. If the soil is very heavy dig extra deep, then set the trees near the surface level, and make hillocks around them to the proper hight for covering the roots well, so that water will not stand around the roots.

Vinegar—Make a large supply from poor quality apples and washings of cider pomace, as directed on page 336.

Kitchen and Fruit Garden.

Those having little forethought or energy will not find much November-work in the Fruit and Kitchen Garden; the enterprising gardener will see an abundance to be done, *and do it*. He will improve the time between now and the setting in of Winter in laying the corner stones as well as the plans for another year's prosperity. He will add to his choice fruits, both large and small; extending his hot-house, cold frame, and hot-bed facilities; enlarge his asparagus beds; and above all, strive to increase the productive capabilities of every rod of his ground, by manuring, subsoiling, trenching, or draining.

Asparagus is a luxury in early Spring. New beds may yet be planted with seeds, but get roots, if practicable, as they will bear cutting a year or two sooner. The soil should be well worked to 2 feet deep, and can hardly be too rich, half old manure will be none too much. A frequent coating of salt upon the bed is valuable. Set the roots 10 to 12 inches apart in rows 2 feet apart, covering the roots 4 to 6 inches deep.

Blackberries may still be set where the ground has not frozen. Protect the New-Rochelle and other choice or tender varieties, in cold climates, by bending down carefully, and covering with a little earth.

Cabbages—Put into the cellar or trenches before freezing weather. Young plants, placed in cold frames, may be made to produce early cabbages just when they will taste most delicious, or sell at a good price.

Celery—Earth up when the soil is dry. Late in the month cover in the trenches with soil.

Cold Frames—Provide plenty room for cabbage plants, cauliflowers, lettuce, radishes, etc., and good covering to lay over during coldest weather. Keep them open, except when there is danger of freezing. Secure some ventilation, even when most thoroughly covered. The sides must be banked up warmly. The extra covering to lay over the sashes may be straw, leaves, blankets, or whatever is most convenient to shut out cold.

Compost—The more the better. See Orchard and Nursery directions for making.

Currants and Gooseberries—Be sure to have enough for a good supply. Other fruits may fail. Set out new roots, make cuttings, destroy borers and other hostile insects, and manure, if needed. Chip manure is good. It pays, in many cases, to remove the old soil from beneath the bushes, and replace with fresh earth.

Drain, with good underdrains, every rod of garden land that is wet, cold, or backward in early Spring. Besides forwarding the work before a hurrying season, and increasing the crop, it will pay in extra earliness alone.

Figs—Remove to cellar, or otherwise protect thoroughly. Barrels set over small trees, and filled with earth, are the most convenient.

Fruit Trees—One can hardly have too many of choice kinds, well planted out. Single trees, ten or twelve years from the seed, often yield greater profits than half an acre of wheat. "A word to the wise," etc. See Orchard and Nursery directions for setting. Also article on page 306, September *Agriculturist*.

Grape Vines, occupying but a fraction of a square rod, often yield more profit than a whole acre of grain! Is there not room for a few more choice vines? Get the best proved varieties at once, and set them where the roots can go down deep in rich soil. Give them plenty of broken bones, old leather, and soap suds.

Mice—Leave no rubbish above ground to harbor them. They will not breed in the compost heap! Set traps, and spare no pains to exterminate them.

Mushroom beds may yet be made. For full directions for culture, see *July Agriculturist*, page 213.

Onions—Give those left in the ground over Winter a slight protection of earth or litter.

Parsneps, Salsafy, and Scorzonera are not injured, but rather benefited, if left in the ground over Winter.

Raspberries—New roots may yet be set out with safety. Bend down and cover lightly with earth the canes of tender varieties wanted for next year's fruiting.

Rhubarb—Divide large roots, and re-set. Cover crowns with coarse manure, to be forked in next Spring.

Spinach—Thin out winter plants to about nine inches apart. Give light covering with straw or litter when severe weather approaches.

Squashes, Pumpkins, etc.—Keep in a dry, cool cellar, or other place secure from freezing. The prize exhibition at the *Agriculturist* Office commences Nov. 5th.

Strawberry Bed—Spent tan bark proves the best winter protection, and it is settled that protection, even in the latitude of the city of New-York, increases the crops materially. Straw or forest leaves will do, if kept down by brush. Saw dust brings in grubs.

Turnips—Let late crops grow as long as there is no danger of freezing. If caught by frost, cover them with earth, until the frost comes out, and then take up.

Flower Garden and Lawn.

The blooming season of nearly all flowering plants and shrubs is over, except the Chrysanthemums. These are now in their prime and glory, and will continue to be, until Winter is fully upon us. See hints and directions for a general clearing up, and preparing for Winter, p. 338.

Climbers, and most shrubs, will be benefitted by slight protection. Take the climbers down from the trellises, and throw a little straw, leaves, or even earth upon them. Shrubs too rigid to be bent over, may be protected by binding straw or matting around them.

Dahlias, Gladioluses, and other bulbs or plants liable to injury by freezing, should be taken up, and put into dry, cool winter quarters.

Hedges may still be planted out. Try a few rods of dwarf pear hedge, setting the trees 2 feet apart, in rows 6 feet apart.

Hyacinths, Tulips, Crown Imperials, Crocuses, and other bulbs, should have been planted last month; but it is not too late now.

Lawn—Give a top-dressing with fine manure. Rolling is beneficial, where the soil is light, and the turf not established.

Perennials—Divide large roots and transplant. They will flower better another season, if transplanted now, instead of waiting until Spring.

Shade Trees of hardy, deciduous kinds, may now be transplanted. Take time to do justice to all their roots.

Terracing, Laying Out Walks, Grading, etc., is appropriate work for this month.

Green and Hot-Houses.

The heated apartments will require special care this month. The great danger with beginners at least, is in giving too much heat early in the season. This is the natural season of rest for most plants, and they should not be stimulated by a high temperature, nor be drenched with water. Where the collections are large, with several houses, or apartments, and early winter bloom is desired, an assortment may be put into one or more houses or rooms and heat and moisture given to force them into growth for flowering. As far as possible, plants of the same nature should be kept in the same room. Some require much moisture and should be so arranged that they can be sprinkled and syringed freely, to maintain a humid atmosphere. Others need less warmth and a drier air which can only be regulated by keeping them in separate rooms.

In the Green-House, very little fire heat will be required, and that only on the coldest days, covering well with shutters at night. Water moderately, just enough to keep the plants from drying up.

Some of the late-growing and half-hardy plants are still in the borders, but all should be taken in or be put in pits by about the middle of November, according to the latitude. A few of the more hardy plants, such as hydrangeas, some of the tea roses, etc., may be strawed up, or have evergreen boughs placed around them and remain in the borders over Winter. It is not the freezing that injures them, but the sudden changes from heat and sunlight to frost and the reverse. One of the best protections where it can be given, is a covering of earth.

Plants in pits will require frequent ventilation while the weather continues warm—much more when first put in than after they have become accustomed to the change. When the weather becomes settled cold, put on the shutters, straw, mats, etc., and if covered with snow let it remain until mild days admit of opening the pits. To guard against mice, place a little poison among the plants, or leave baited traps.

One of the first things in the heated department, is to provide a good stock of cuttings for Winter and early Spring blooming plants. Give them a moderate heat until rooted, after which they may be forced into rapid growth. See that all the plants requiring potting are changed at once. Cut back straggling and weak plants, to form a good bushy head and infuse new vigor into them. A weak solution of guano-water, or the leachings of hen manure may be given to lagging plants.

Watch carefully for insects and destroy them before they increase. Dipping the affected plants in water heated to 130° is a favorite method of destroying insects with many florists. Some add a little grease, or sulphur, or both. Subsequent syringings will soon clean them.

Apiary in November.

Prepared by M. Quinby—by request.

Bees that have received seasonable attention, will need little care this month. Any neglect they should not be longer delayed. Unfilled boxes should be safely stored for next season's use; any dry combs in them, may remain for another year. Secure them from the mice, or they will be spoiled. Put covers to boxes exposed to the weather.... Hives containing bees, may be painted now, without seriously injuring them. It is not always best to paint hives, but when it is desirable let it be attended to at this season.... Honey to be strained that has stood a long time, after the bees are removed, will require warming, to make it drain out freely.... Contract the entrance to the hives, sufficiently to exclude the mice.

Fruit Growers' Meetings.

These gatherings at the office of the *American Agriculturist*, at 2 o'clock P. M. on Thursday of each week, continue to increase in interest—as many as a hundred persons specially interested in fruits being sometimes present. The leading fruit men of this vicinity and elsewhere, amateurs, orchardists, nurserymen, and business men of the city who have their country places, come together, choose a chairman, and spend one to two hours in testing fruits, discussing their merits, examining new sorts, talking over modes of culture, and the best varieties, in a social manner. In this way an interesting and profitable hour or more is passed, and the growth of good fruits is promoted, while poor kinds receive their just deserts. From the free manner of the discussions, it is not a good place to send a poor "ax to grind," unless the owner desires to have the edge ground square off. We do not present a detailed report of the meetings, for want of space; but some of the good hints brought out, from time to time, will be found scattered through our paper. See report on Adirondac grape, page 330, and the list of commended pears, and other lists, in the basket columns.

Exhibition Tables at the Office of the American Agriculturist.

During the past month our tables have presented an attractive and instructive display of various products, especially of fruits, the daily show being from 150 to 250 plates of apples, pears, grapes, and other fruits. A great number of apples and pears were exhibited their proper names. Many monster pears have been shown, some of them excelling in size any specimen of the same variety previously reported. A few are noted elsewhere. W. S. Carpenter alone, exhibited 100 varieties of apples. The following articles have not been before reported.

Apples.—Porter, Fall Pippin, seedling for name, Cheesebrook Russet, from R. Williams, of West Bloomfield, N. J.... Mixie, Summer Queen, from J. Trowbridge, New-Haven, Conn....Fall Queenes, variety for name, from Chas. Adams, of Linden, N. J....Sour Bough, Red Gilliflower, from A. J. Caywood, of Hoboken, N. J....Golden Gate, Fall Pippin, R. G. Greening, from J. Van Riper, of Lodi, N. J....Seedling Blush, from J. L. Lockwood, of Stamford, Conn....Dutch Codlin, Golden Russet, Jersey Sweet, Jersey Greening, from N. Y....Alexander, Egg-Top, from S. B. Noble, of Chatham Four-Corners, N. Y....Blush Apples for name, from John Moody, of Illinois, N. J....Alexander (fine), from Mrs. Dr. Peter, of Fawling, N. Y....Porter, from Dr. Ward, of Newark, N. J....Golden Pippin, from P. T. Stephens, of Nyack, N. Y....Seedling for name, from P. V. Le Roy, of Peekskill, N. Y....Gloria Mundi, from S. T. Brown, of Bergen Point, N. J....Cod Apple, from E. H. Allen, of N. Y.... Dutch Codlin, Golden Pippin, Weaver, of Fordham, N. Y.... Varieties for name, from G. W. Douglas, N. G. Mattison, F. C. Good, J. G. Holbrook, Wm. Agnew & Sons, J. W. Rockwell, Mr. Gilbert, Dr. Underhill, Dr. Lawrence, Mr. Bonn.

Pears.—Beurre d'Anjou, Louise Bonne de Jersey, Flemish Beauty, Beurre Diel, Seckel, Duchess d'Angouleme, Vicar of Winkfield, Striped Dean, Urbaniste, Beurre Gris d'Hiver, Doyenne Boussock, White Doyenne, Orange Bonne Ardlet, 10 varieties for name, Belle Lucrative, from J. Van Brunt, of New Utrecht, L. I....Bartlett (fine), Louise Bonne de Jersey, Branch of Flemish Beauty, extraordinarily large, Beurre Diel (fine—4 weighed 4 lbs. 4 ozs.), Duchesse d'Angouleme, Vicar of Winkfield (4 weighed 3 lbs. 2 ozs.), Glout Morceau, from Mr. Mavonough, of Irvington, N. J....Bartlett (specimen large) Duchesse d'Angouleme, from Thos. Vernon, of Brooklyn, L. I....Beurre d'Anjou, from Thos. Andrews, of West End, N. J....Beurre Bonne, Pendant d'Aremberg, Seckel, from Bronxville, from J. P. Swain, of Bronxville, N. Y....Fondante d'Automne, Urbaniste, Vicar of Winkfield, Orange, 8 native, variety for name, from J. G. Holbrook, of Chappaqua, N. Y....Seckel (fine), from D. P. Halsted, of Harrison, N. Y....Seckel, Beurre Diel, Pear of Pean, variety for name, from Isaac Hicks, of Hempstead, L. I....Duchesse d'Angouleme, (very fine—from a hedge, on guince, of 1000 feet, 6 years old—dwarf), Beurre Diel (very fine), Urbaniste, from T. W. Field, of Brooklyn, L. I....Beurre Diel, Seckel (large), Louise Bonne de Jersey, from G. S. Stephan, of Hastings, N. Y. Winter Nellis, variety for name, from H. A. King, of Long Island Brook, N. J....Louise Bonne de Jersey (fine), Bartlett (very fine), from P. T. & J. T. Ten Eyck, of Middletown Point, N. J....Duchesse d'Angouleme, 4 varieties for name, from Mr. G. O. Street, of Mt. Vernon, N. Y....Beurre d'Anjou, variety for name, from I. S. Carlton, of Richmond Valley, Staten Island....Beurre Diel, Beurre Bosc (very fine), from A. Youngs, of Matinicock, L. I....Maria Louise, from N. W. Cheeseman, of N. Y....Louise Bonne de Jersey (very fine), from Duchesse d'Angouleme, from Mrs. Pearson, of Newtonkirk, L. I....Urbaniste, from Dr. Riggs, of Plainfield, N. J....Flemish Beauty, (very fine—weighed 16 ozs.—16 same size on tree 12 feet high), varieties for name, from C. Bement, of Bloomingdale, N. J....Des Mons Leon Le Clerc (very fine), from John Egan, of New Brighton, Staten Island....Pound Pears, from J. Ridgway, of Staten Island....Gipe Pear, from R. R. & G. Ward, of Westchester, Penn....Duchesse d'Angoulemo (fine, on dwarf tree planted last April), from S. R. Trimbly, of Bergen Point, N. J....Osway Beurre, Beurre Capiaumont, Beurre Clairgeau, Orange Judd, of Flushing, L. I....Beurre de Capiaumont, from Jas. Hogan, of Rahway, N. J....Duchesse d'Angouleme, from Henry C. Schroeder, of Red Bank, N. J....Nec Doyenne, Duchesse d'Angoulome, Louise Bonne de Jersey, from E. Williams, of West Bloomfield, N. J....Chinese Sand Pear, Seckel, Duchesse d'Angoulemo, Vicar of Winkfield, 13 varieties for names, from S. T. W. Sanford, of Ravenswood, L. I....Beurre Clairgeau, from J. R. Rappelye, of Astoria, L. I....Duchesse d'Angoulemo, Beurre Clairgeau, Beurre Piquerre, Calebasse Nertuan, Louise Bonne de Jersey, Howell, Seckel, from B. Stevens, of West Hoboken, N. J....Seckel (very fine), from G. M. Usher, of Port Richmond, Staten Island....Chinese Sand Pears, from A. Leggett, of Clifton, N. J....Duchesse d'Angoulemo (very large, Orange, weighed 21 ozs., circumference 13 inches,) from A. Childs, of New Market, N. J....Duchesse d'Angoulemo (dwarf), from Wm. Day, of Morristown, N. J....Urbanistes, from P. B. Tyler, of Springfield, Mass....Virgalieu (fine), from W. B. Smith, of Belleville, N. J....Flemish Beauty, from Dr. Freeman, of Astoria, L. I....Choke Pear (double), from W. Ely, of Bull's Ferry, N. J....Rappelye Seedling, from D. R. Remsen, of Astoria, L. I....Rappelye Seedling, from B. S. Pike, of N. Y. ....Bartlett, Belle Lucrative, Swan's Orange, Golden Beurre, variety for name, from Dr. Ward, of Newark, N. J....Varieties of Pears for names, from Chas. A. Whitney, D. S. Manners, J. W. Evarts, J. H. Gibson, I. S. Morris, C. S. Rust, Mr. Cross, Mr. White, John Ruhtyen, N. F. Graves, R. Lewis, Underwood Farm, J. C. Mareh, Wm. F. Heins.

Grapes.—Michigan, Catawba, Isabella, variety for name, from N. B. Haskell, of Monroe, Mich....Black Hamburg, Damascus, from D. R. Remsen, of Astoria, L. I....Catawba, Isabella, from John Cole, of Tompkinsville, States Island.... Montgomery, from I. L. Young, of Poughkeepsie, N. Y.... Purple and Amber Grapes, (Blood's Seedling,) from Dr. Ward, of Newburgport, Mass....Delaware, from W. H. Honeyne, N. Y. City....Seedling "America," (clusters weighed 4 ozs.) from P. T. & J. T. Ten Eyck, of Middletown Point, N. J....Adirondac, from J. W. Bailey, of Plattsburg, N. Y....Catawba, from Rev. J. Weaver, of Fordham, N. Y....Isabella, Clinton, from E. Williams, of West Bloomfield, N. J....Seedless Grapes, from S. Gaylord, of Terryville, Conn....Concord, Hartford Prolific, Gerry & Sons, of Bridgeport, Conn....Grapes from Frederick Kindley, of New Holland, Ind....Isabella, extraordinary large, from John Egan, of Staten Island....Black Hamburg, Golden Chasselas, White variety for names, from Chas. Mandewirth, of Flskill, N. Y....Scedling Grapes, from Mr. Pollock, of Morrisania, N. Y....Native grapes, from Mr. Patten, of 110 Broadway, New-York City. Varieties of Grapes for names, from J. Moody, W. Craig, Prof. Bradbury.

Peaches.—Union Peach, from D. Sutphin, of Washington Market, N. Y....Catherine Peach (one in pot, 3 years from bud, full of fruit, from Jas. Wiggins, gardener to Jas. Brown, Esq., of Weehawken, N. J....Red-cheeked Peach, from Sutphin & Lyon, of 100 Washington Market, N. Y....George the IV Peach, from Rev. J. Weaver, of Fordham, N. Y.... Bergen's Yellow, from Geo. Hayward, of Brooklyn, L. I.

Other Fruits.—Curious grown plums, from H. T. Hewitt, of Scotch Plains, N. J....Seedling Plums, from W. Smith, of Belleville, N. J....Raspberries (3d crop), from Mr. Carnell, of Mt. Vernon, N. Y....Cranberries (very fine), from Chas. L. Davis, of Plymouth, Mass....Cranberries, from Thos. Hancock, M. J. Spence, of Edenvale, L. I....Tomatoes (fine), from A. Peyrot, of Tremont, N. Y....Tree Tomato (in full bearing), from E. Williams, of West Bloomfield, N. J....Clusters of Tomatoes, from John Metz, of Hudson City, N. J....Perfected Tomato (very large), from H. Clark, of Yonkers, N. Y.... Red Currents (Sept. 28), from S. Bell, of N. Y. Orphan Asylum....Pear Quinces, from Mr. Cortelyou, of Marsland, Staten Island....Apple Quinces (very fine—one weighed 17 ozs., circumference 18 inches, from J. C. Van Nest, of North Orange, N. J....Apple Quinces, (fine—11 weighed 7 lbs.), from A. G. Syms, of Rahway, N. J....Osage Orange fruit, (fine), from Rev. J. Weaver, of New Utrecht, L. I....Figs from D. R. Remsen, of Astoria, L. I.

VEGETABLES, SEEDS, ETC.

Potatoes.—Pink Eye Russet, Cuzco, Coppermine, Prince Albert, Garnet Chili, Jersey Mercer, New Seedling Mercer, Peach Blow, from E. Williams, of West Bloomfield, N. J....Prince Albert, Peach Blow, Potato from New Mexico (fine), California Reverse, Early Purple, Early Pink Eye, from F. F. Heins, of Woodstock, N. Y....Peach Blow (230 bushels on just one acre), from G. P. Gott, Mulford Station, N. J.....Peach Blow, from Wm. Forbester, N. J....Cuzco, Mexico, Potato with 9 heads, from P. Malone, of New Durham, N. J....Prince of Wales, Prince Albert, from E. A. Bulkley, of Williamsport, Mass., Pink Eye Russet, from Mr. Cortelyou, Jersey, from John Curtis, of Chatham Four-Corners, N. Y....Peach Blow, from Jos. Sedlington, of North Islip, L. I....Red Sweet Potato, from R. R. & G. Ward, of Westchester, Penn....Nansemond Sweet Potato (weighed 8¾ lbs.), from W. F. Walker, of Goldsboro, N. Y....Sweet Potato (weighed 2½ lbs.), from W. A. Cummings, of Essex, Conn.

Other Vegetables.—Blood Beets (very large), from Conrad Scholl, of Washington Square, L. I....Blood Beets (fine), from H. Schotte, New-York City....Rutabaga and Long Blood Beets, from A. H. Smith, of Stamford, Conn....Silver Skin and Red Onions (fine), from Mrs. E. G. Wheeler, of Hartmount, N. Y....Onions (very large, weighed 3½ lbs.) from Conrad Scholl, of Washington Square, L. I....Vegetable Marrow Squash (very fine), from O. A. Van Lennep, of Orange, N. J....Cultivated Carrots, from J. Van Brunt, of New Utrecht, L. I....Cotton Plant, (very fine—raised from seed from *Agriculturist* office) from Wm. I. Serrell, of Bayonne, N. J....Island of Sea Island Cotton Plants, (growing) from A. Harris, of 174 East 17th street, N. Y....Super moth Nutmeg Melon, from J. Van Riper, of Lodi, N. J.... Vegetable Egg Gourd, from E. Hall, of Deerpark, L. I.... Fancy Gourds, from Jacob F. Braun, of Williamsburg, L. I.... Plant of Red Peppers (very fine), from G. M. Usher, of Port Richmond, Staten Island....Italian Millet, from Mr. Fuller, of Newburgh, N. Y....Millet, from J. McElwee, of Walker Valley, N. Y....Corn (from battlefield of Antietam, Md.), from J. Van Brunt, of New Utrecht, L. I....Cotton from J. W. Rockwell, of Ridgefield, Conn....Water Nuts, (very singular), from Fritz Meyer, of Dessau, Germany.

FLOWERS.

Dahlias (fine collection), Cut-flowers (late and rare), from C. S. Pell, of N. Y. Orphan Asylum....Cockscomb Seedling Phloxes and Verbenas, from W. & J. Cranston, of Hoboken, N. J....Bouquet of flowers, from Miss Emily Studley, of Thompson's Station, L. I....Dahlias, from A. S. Fuller, of Brooklyn, L. I....Cut-blooms of Balsams and Pansies, (beautiful), from Rev. J. Weaver, of Fordham, N. Y....Dahlias, from Mr. Lee, of Brooklyn, L. I....Dahlias, from A. Saltford, Dansprerie, from H. Bussard, of Yonkers, N. Y....Dahlias, from H. C. Ward, of Newark, N. J....Cut-blooms of Cockscomb (very fine), from J. Fossett, of Mott Haven, N. Y.... Phlsiantins Albens, from D. Cordier, of College Point, L. I. Blooms of Passifiora Decaine (very beautiful), Tuberose, Geranium, etc., from A. P. Cummings, of N. Y.

MISCELLANEOUS.

New Jersey Marl, from Ed. Pitcher, of Eatontown, N. J.... Fruit Labels, from Isaac Hicks, of Hempstead, L. I....Egg (large—weighed 4 ozs.—common fowl,) from S. W. Thomas, of Hudson City, N. J.

Men of the noblest dispositions think themselves happiest, when others share their happiness with them.

Containing a great variety of Items, including many good Hints and Suggestions which we give in small type and condensed form for want of space elsewhere.

Read the Calendar.—A large number of hints are condensed into the Calendar of Operations.—This is not a stereotyped affair, used from year to year, but is written for every paper, and generally revised by a new hand, and hence contains new suggestions in every month in every year. Any additional items in this department will be gladly received. We mean to make the Calendar alone worth far more than the cost of the paper.

Where are the Armies?—The map on page 248 will help to follow the great Western armies in Kentucky, or in Tennessee if they go there. The magnificent map of *Virginia* offered as a premium, on page 252, gives the most minute localities of every part of that State, so that every movement of the great Eastern armies can be readily traced. This map is alone worth a dollar, at the usual price of such maps. The maps of the Southern States, and of the whole United States, are also very desirable. We cannot promise any of these maps on the same terms after this month.

Bring Out the Pumpkins.—We invite all who have big pumpkins or squashes, or those specially valuable, if not so large, or fancy gourds, to contribute them to the *Show* to be held Nov. 5th. See particulars on page 349. Let us have an exhibition that will far excel the similar one now in progress in London, under the auspices of the Royal Horticultural Society, and show that, in fact "Americans *are* some pumpkins."

Exhibition of Northern Grown Cotton.—From the few responses to our proposition for a prize exhibition of Northern Grown Cotton, we are in doubt whether many persons are preparing to exhibit. One writes that cotton has gone to so high a price that he can spare none for the show. Will all who are intending to exhibit specimens please write *immediately*, giving particulars, and offering suggestions as to best arrangements for the exhibition, rules for examination and awarding premiums, etc. For several reasons the exhibition can not take place before the middle of December. After hearing from our correspondents we can make a more definite announcement.

The Premium Strawberry Plants.—We have sent out about **40,000** plants the past season, and so far as we have heard, all parcels have gone safely and in good order, with barely two exceptions. This is remarkable, and demonstrates the feasibility of sending plants safely by mail, when rightly put up. These plants, multiplied as they will be, will do much toward introducing at least one good variety over the country, and add to the pleasure of a large number of persons. This is one of the good results of the reduction of postage on plants and seeds. Can not our readers in the *British Provinces*, by petition or otherwise, induce their government to reduce the postage on such articles? To send 8 ounces of plants or seeds by mail 1,500 miles in the States, cost 8 cents, and only 16 cents to any distance. To send the same amount to the British Provinces by mail, often costs $1.60. Some Canadian Postmasters have passed them along, after the 1 cent per ounce has been paid here.——☞ In every case, we have sent on in advance to the recipients of our premium plants, a printed circular, notifying them of the time of mailing them. We are sorry to learn that some did not get the circulars, for they contained several good hints in regard to the best mode of cultivating and multiplying plants.

"Apple Bees" for Soldiers.—L. Palmer, Luzerne Co., Pa., sends to the *American Agriculturist* an account of an "Apple-Cut" in that neighborhood for the benefit of the soldiers. The neighbors, from a mile or two distant, met on a given evening, each bringing a contribution of fruit, which, with the help of patent parers, was quickly prepared for drying. The example is a good one for every locality where fruit is abundant. The Sanitary Commission assure us that there is no danger of too much fruit being sent to the army, and that no more welcome contribution can be made. We call for at least one thousand bushels of dried apples to be forwarded by our subscribers. See Note on page 328. A single peck (8, quarts or 6 pounds) of dried fruit from each family receiving the *Agriculturist*, would furnish *fifteen or twenty buskels* to every regiment now in the field, or likely to be there, though this would be only a pint to each man.

Acknowledgement.—We return thanks to the Officers of many Agricultural and Horticultural Societies, (too numerous to refer to in detail) who have kindly favored us with complimentary tickets and invitations. These have sometimes included a dozen fairs occurring on the same day. In the pressure of other duties, we have been able to visit only those most accessible.

Agricultural Exhibitions.—Though the all-absorbing war excitement frightened many Agricultural Societies into postponement of their annual exhibition, we are glad to note that those which have been held have generally been about as successful as in the average of former years, and in many instances the success has exceeded that of any previous year.

Brooklyn Horticultural Society.—The recent exhibition of this Association at the Academy of Music, was a complete success, both in the amount and character of the articles shown, and the full attendance of visitors. The fruits, particularly grapes and pears, were of the finest description. In the floral department were splendid collections of seedling verbenas, petunias, gladioli, etc. One of the chief attractions was the large show of ornamental-leaved plants, which are deservedly coming into popular favor. This Society has taken rank among the very first in the country, and is greatly improving the horticultural taste of community.

New-York State Agricultural Society.—The Annual Exhibition of this Society, held in Rochester, Sept. 30th to Oct. 3d, though somewhat less successful pecuniarily, than last year, was quite satisfactory. Unpleasant weather, except on the last day, greatly diminished both the entries of articles for exhibition and the number of visitors. There was a good show of Cattle, particularly of Herefords and Ayrshires. Sheep attracted more attention, particularly mutton sheep; South-Downs, Hampshire-Downs, and Shropshire-Downs of excellent quality were shown; Merinos were not as well represented. The display of implements was large, but contained few novelties. The Horticultural Department, under the able superintendence of Mr. Wick, presented very attractive appearances. Altogether, the exhibition was highly creditable to the Society, occurring as it did under the adverse influences of war times and rainy weather.

Queens County Agr. Society, N. Y. The Annual Exhibition of the Society was held this year on the Fashion Race Course—the regular racers of course, being absent. The display was large, especialy in fruits, flowers, and horses, and resulted in large money receipts—amounting to over four thousand dollars.

Fall Plowing for Corn.—John Johnston, of Geneva, N. Y., writes: "I do not agree with your remarks on page 300 of October *Agriculturist*. I have never yet good crops of corn from Autumn plowing. The later in April or May I can plow, and get the corn in before or by May 20, the better the crop. I wish you could see my corn now growing on quite stiff land, where the plowing was finished May 17, the harrow set agoing in the afternoon of the days the ground was broke up, and the corn drilled in as soon as the plowing and harrowing were finished. I have seen the time when, if a farmer planted such land with corn, he would have been thought to know little about raising corn; yet I have had many good crops of corn on the same land for the last 20 years, and I think this year's the best."——But, friend Johnston, you have not told the whole story. Your stiff land is well underdrained, and thoroughly and deeply cultivated, and needs none of the benefits of the course we recommend. Though clayey, it is made dry and pulverulent, and the water being drained out of it, the air gets in during Winter as well as Summer, without turning it up, with plow, in Autumn. Such land is always ready to work, is warmer in Spring, and it stands to reason that on such a soil, a fresh seed-bed, if newly worked, should be just the thing to start the corn up and push it into vigorous growth at once.

Good Wheat in Central New-York. Referring to the *Agriculturist* crop reports, John Johnston of Canandigua Co., writes: "We have excellent winter wheat. I know several fields of white wheat yielding 36 to 40 bushels an acre. These were on summer fallow, or on grass or clover land plowed in August, and top-dressed with well rotted manure before sowing."

Spring Wheat at the West.—Wm. I. Gilchrist, of McGregor, Iowa, writes to correct our estimates of last month. He is a dealer in wheat at that point which he calls "one of the greatest *primary* grain markets in the world, having 12 counties in Northern Iowa and Southern Minnesota tributary to it. From that centre over 2¾ *million* bushels of wheat were sent east during 1861." Mr. G. reports that "Spring wheat is a decided failure in Northern Illinois, Wisconsin, and nearly all through Iowa—probably not three-fifths of a crop, and that of inferior quality, owing to the chinch bug. Last year the wheat of all this region, if taken collectively, would make 'No. 1 Milwaukee Club;' the present crop will not make No. 2. In Minnesota, Spring wheat is fair both in quantity and quality."

The Pear as a Hedge.—Very fine Duchesse pears have been placed on our tables, which were raised by Mr. T. W. Field, of Kings Co., L. I., on a hedge-row of this variety. He has 1,000 feet of Duchesse on the quince stock, set 2 feet apart, in West rows, and well cut back. They have been planted 6 years, and are now giving good crops of extra large pears, one of which weighed 21 ounces. The hedge will not turn steek, but forms a fine screen, thus combining profit and beauty.

Large Specimens of Fruit.—The Exhibition Tables at the office of the *American Agriculturist* bear testimony to the general abundance and excellence of fruit this year. The display for weeks past has been such as we have seldom seen equalled at any County Fair. Besides the great variety shown, several extraordinary specimens have attracted much attention. Among these we may mention: two Duchesse D'Angoulemе pears, one from Mr. Child, Newmarket, N. J., the other from T. W. Field of Brooklyn, N. Y., each weighing 21 oz.—a Flemish Beauty from C. Devlin, N. Y. City, weighing 16½ oz.—Mr. McDonough of Irvington, N. J., exhibited 4 Beurre Diels, weighing together 4 lbs. 8 oz., and 3 Vicar of Winkfields weighing 2 lbs. 2 oz.—Three Bartletts from P. T. & J. T. Ten Eyck, Monmouth Co., N. J., weighed 2 lbs. 6 oz., and 3 Louise Bonne de Jersеys, 30 oz. An apple quince exhibited by John C. Van Etten, North Bergen, N. J., measured 12¾ inches in circumference, and weighed 17 oz.

Prize Essay on Peach Culture.—Wm. Robbins, Suffolk Co., L. I. But few essays on this topic were received in competition for the prizes. Although these contained good suggestions, the Committee did not deem either of sufficient merit for publication.

Will Tobacco Mix? asks "Connecticut River Subscriber." The different varieties, when blooming together, will doubtless hybridize the *seed* so as to injure it for another crop. The growing plants will not be changed in character, until after the seed is affected.

Silk Weed.—Our Canadian neighbors are utilizing the silky egrets or coma of the Asclepias *cornuti*, by mixing it with cotton, producing what they term "Canadian Silk Cotton." They also manufacture a flax from the stems of the Asclepias *incarnata*. This plant is nearly allied to the Calotropos *gigantea* of India, which, mixed with cotton, forms the celebrated Mudar Silk Cotton, and from the fibres of which is made the strong "Bowstring Hemp" of India.

Gazanea Splendens.—M. J. Scott, Franklin Co., O. This comparatively new perennial is not hardy, but requires winter protection in a pit or cold house. Unless having this protection, it is best to obtain fresh plants from a florist, to set out every Spring.

"Packages of Stationery"—A Caution.—Letters are constantly reaching the office of the *Agriculturist*, from different parts of the country, making inquiries about this party or that one, who is sending out circulars, and advertisements, offering "packages of stationery" which are represented to contain any quantity of writing materials, articles of jewelry, etc., etc. "worth a dollar," but "in consideration of the times" to be sold for 25 cents, with a large discount by the quantity, and a watch, or some valuable (or value-less) article, thrown in. As a general reply, we say, that these parcels are not worth buying. They usually consist of a large envelope containing a few common envelopes, and sheets of paper, a sheet of recipes gathered from newspapers, a cheap pen-holder or two, and sometimes a brassy ring, or other trinket—the whole worth, perhaps, 4 to 6 cents. Better buy your paper and pens at a store near home, and save half or three fourths of the money. Nobody is fool enough, or generous enough, to offer 25 cents' worth of stuff, with a watch thrown in, for less than their cost. A good round profit above advertising and other expenses is always provided for.

American Cyclopedia.—Vol. XV of this sterling work is out, and filled with interesting articles—extending alphabetically from "Spiritualism" to "Uzziah." One more volume completes the series. We are obliged to defer to another month a more particular notice of Vol. 15. For the general character of this great work, see description under Premium No. 11, on page 346.

Hot Sucking a Cow.—A writer in the London Field relates, that on visiting his cow shed he found a newly-calved cow quietly lying down chewing her cud, and a huge rat lying at full length between her legs sucking vigorously at one of her teats. He had previously noticed that the cow gave less milk than she should have done so soon after calving.

Apples for Milch Cows.—C. D. Walters, Essex Co., N. J. Sound apples judiciously fed to cows will not lessen, but rather increase the flow of milk. They afford an excellent change of diet. Feed them at the rate of five to eight quarts night and morning.

Sheep Disease in Michigan.—Charles Goodrich, of Ionia Co, writes that a troublesome disease has broken out among sheep there. "Lumps appear on the throat, generally one on each side; these gradually enlarge and close the gullet and windpipe to which they are attached, choking the sheep to death. What is the cause and remedy?"

Small Pox in Sheep.—Recent English agricultural journals give accounts of the ravages of small pox among sheep. It is believed to have been introduced by a flock imported from Holland, and has proved disastrous to many flocks. Precautions are being taken by inoculation, etc., to prevent its further spread.

To Cure Kicking Horses.—"J. R.," in the Rural New-Yorker, recommends the following plan: "Let the horse stand between two partitions. Bore a two inch hole in each, on a horizontal line, about one and-a-half inches above the horse's hips; take a round stick long enough to reach across the stall, and place it in the holes, and put a pin in each end of the stick so that it can not fall out. The horse may try to kick, but will not be able, as the stick will prevent the necessary elevation of his hind quarters, and after a few attempts, he will give it up." This may answer temporarily for an already spoiled horse: better never teach a horse to kick.

Martingals for Horses.—C. B. Wells, Cayuga Co., N. Y. Properly broken horses will never need a martingal. It is used to keep the horse's head in good position, which can be done with the reins if the horse has been rightly trained. It may be of service to control a horse which has learned the vice of rearing, but ordinarily it imposes an unnecessary and painful restraint upon the freedom of motion of the animal.

What is Ringbone?—Young Farmer, Sullivan Co., N. Y. Ringbone in the horse is an unnatural bony growth forming a circular excrescence upon the coronet, or part of the hoof immediately above the junction of the hair and hoof. It results from a strain, usually while horses are young, and causes one of the worst and most incurable forms of lameness.

Skunks versus Rats.—J. J. H. Gregory writes to the New-England Farmer, that he has voted the freedom of his farm to skunks, in return for the service they have rendered in freeing his premises from rats. The latter vermin had taken up their quarters under the barn, but when a skunk presented himself, they gave a wide berth to their unsavory neighbor, and totally disappeared. Mr. G. thinks skunks attack poultry only when they can get nothing else, and that their principal food is beetles and other large insects.

Are Coal Ashes Worthless?—"John." No Sir; neither are they of great value. Still they are worth saving. Their fertilizing power will vary, of course, according to the kind of coal used, and the amount of woody substances employed in lighting the fires. A chemist, who analyzed several specimens of ashes taken from an ordinary grate, states that "they consist almost entirely of the various earths, a small portion of charcoal, and the saline matters, of which the sulphate of lime (gypsum), and lime constitute about one quarter." Turning from science to experience, we find that such ashes make an excellent dressing for grass land, and in some conditions of the soil, give a fine growth of turnips. We have found them useful as a mulch about the roots of fruit trees. Of their utility for walks and roads—the ashes to be covered lightly with gravel —we have often spoken in the *American Agriculturist*.

Wheat, Rye, Oats, and Corn in Wisconsin—Large Yield of Wheat.—Wm. H. Baker, of Racine Co., Wis., writes to the *American Agriculturist*, Oct. 8: Winter wheat has done finely. As an instance, Nathan Burnham, near Racine, sowed 4 bushels of bearded wheat on about 4 acres of clayish soil, well tilled, but nothing more, and measured up 158 bushels, besides some not screened, making over 40 bushels per acre. Farmers are sowing winter wheat very largely this Autumn.—Rye and oats have done better than the average. Corn is happily disappointing all, and turning out well. I have over an acre of sorghum looking finely; no frosts to disturb it as yet.

Wheat Thrashing out Well.—Charles Goodrich, of Ionia County, Mich., writes to the *American Agriculturist*: "I find that upon thrashing, wheat turns out beyond all calculation. In this county it is the best of many years. I do not know of a field grown on well cultivated summer fallow, that has not yielded 35 bushels to the acre, while 30, 40, and even 45 bushels are by no means uncommon. I must boast a little for our county, by telling that one field of six acres yielded over 52 bushels per acre. I had 400 bushels myself on ten acres. Corn well filled; early potatoes poor, late promise well."

New Rice Fields.—The high price of this commodity resulting from non-intercourse with the States whence the chief supply has usually been drawn, is stimulating experiments in new localities. The California Farmer urges cultivators to introduce it upon the lands about the streams, mouths of rivers, which are now lying waste on account of the annual floods. Messrs. Judd & Wilder have just sent to San Francisco an extraordinary crop raised in the Sandwich Islands. An area of 15 acres and 80 feet was cultivated, which turned out 89,200 lbs., or 5,935⅚ lbs. per acre. This, at 6 cents per lb., gives an income of over $350 per acre.

Contract to Raise Onions Offered.—Wm. J. Spence, who claims to be on some of the ostracized "barren or waste lands of Long Island," has tried his hand at onion raising for two years, and is well pleased with the result so far as amount and quality of the crop is concerned; his only difficulty has been in marketing or keeping them. He says that if any one will contract to take nice red, or white silver-skinned onions, delivered at the Railroad in Autumn, at 50 cents per bushel, he will bind himself to furnish 1000 bushels or more, raised on the said lands, and consider the contract a very good one.

Agricultural Inventions in One Year.—In the official list of "Agricultural Inventions or Discoveries for the year 1861," and a war year at that, we count 25 bee-hives, 51 cultivators, 26 churns, 70 harvesting implements, 26 corn planters, 41 plows, 45 seeding machines, 9 thrashing machines, and several other farm and garden implements in smaller numbers.

Size of Cistern and Kind of Pump.—H. Schepper, Owen Co., Ind. Eight feet deep and seven in diameter in the clear, is a good size for a family cistern. This will hold over 3,000 gallons, or 95 barrels—enough for ordinary use. When exposed to freezing, a chain pump is preferable. A Douglass or other iron pump is convenient in the kitchen, or where otherwise protected from frost.

Cisterns and Wells—Convenient way to Examine them.—It is probably not known by most persons, that the bottom of a cistern or deep well even, may be thoroughly inspected for filth, or lost articles, by using a common mirror (looking-glass). When the sun shines, hold the mirror so that the light will be reflected in a bright spot at the bottom of the water, and a pin can be seen at a depth of 10 to 20 feet or more. We have in this manner seen fishes at the bottom of thirty to forty feet of clear water. If this can be did by intervening objects, use two or more mirrors to bend the light by double or triple reflections to the desired point. We have thus thrown the light coming into the dining room window, by one mirror through the door into the kitchen, by another to a corner of the latter room, and by a third mirror cast it down into a cistern sufficiently strong to see a small angle worm at the bottom.—*Amer. Agriculturist.*

Grapes and Grape Wine.—Samples from H. H. Brown, Washington Co., Pa. The wine with 1 lb. sugar to 1 gallon of juice is too acid to be palatable; that with 3 lbs. sugar to the gallon is a mild, pleasant drink. The fruit and wine were exhibited at the Fruit Growers' Meeting, and those who examined them unanimously pronounced the grapes Isabellas.

Grape and Fruit Humbugs.—The present Autumn is developing an amount of rascality in fruit trees and vines, that is almost incredible. The favorable season has produced fruit on nearly every tree, shrub, bush and vine. Almost daily gentlemen bring to the office of the *American Agriculturist* specimens of poor fox grapes grown on vines which they bought at high prices a few years ago, supposing they were getting the best standard sorts. They have lost their money, and time, and patience.—We pity them, but they have themselves to blame somewhat, and for this reason: Most of these vines, if not all of them, were purchased, not of regular nurserymen, those who have a reputation to sustain, but of temporary peddlers and dealers who annually open a shop on Broadway, or a stall in the markets, or hawk around the country trash labeled with any name the purchaser may chance to call for. This applies to fruit trees, flowering plants, etc., as well as to grapes. When the truth becomes known a year or two afterwards, the rascals are *non-come-at-ibus*.—There are more left of the same sort.

Seedless Grapes.—S. Gaylord, of Litchfield Co., Conn., sends specimens of wild grapes of small size, reddish color, which he thinks will prove valuable for cooking, as they are *destitute of seeds*. They are indeed seedless, but it is probable that the hard pulp and the poorer flavor will weigh against the absence of seed. They may answer for sauce, but, as a grape, can not be compared with the standard sorts, such as Hartford Prolific, Concord, Diana, Delaware, etc.

Grape Blight Prevented by Bones and Boots.—F. A. Denny, Macoupin Co., Ill., writes to the *Agriculturist* that he kept the blight, (mildew) from his Isabella vines, while those of his neighbors were ruined, by digging trenches and filling them with old bones, shoes, rags, etc., which he gathered at little cost. Probably the *drainage* afforded by the trenches had most to do with the health of the vines, though the bones and rags furnished good fertilizing materials.

Bleeding Grape Vines.—A. C. Eaton, of Huron Co., O., writes to the *Agriculturist*: "Burn woundeel parts with a red-hot iron, or, first put on shoemaker's wax, then use the hot iron. This drives the melted wax into the open pores and stops the out-flow of sap."

"Vineland Lands."—To a number of inquirers. We have not yet been to "Vineland," and can give no reliable information about the lands in question, until we can get time to go and see for ourselves. The reports are that a large tract of land in New-Jersey, southeast of Philadelphia, has long been owned by England, and that it is now offered on sale in small plots or farms. Of the quality of the land, the title, etc., we can as yet say nothing from actual knowledge. Of course, any one thinking of investing, or fixing a home there, will first make personal observation, and thorough investigation.

Peach Trees in Pots.—This method of growing dwarfed trees is coming into favor with amateurs. Though it would hardly pay to raise such peaches for ordinary marketing, they present such a handsome appearance, when in bearing, as to be a fine ornament in the green-house. A beautiful specimen of the Catherine Peach grown in this way, by James Wiggins, gardener for Jas. Brown, Esq., Weehawken, N. J., is now on exhibition at the Office of the *American Agriculturist*. It is 3 feet high, the limbs spreading about 16 inches each way from the center. It yielded 19 well ripened peaches, part of which still remain on the tree. It is growing in a 13-inch pot, and is apparently as thrifty as any of its taller relatives standing in the open field.

Names of Trees.—"John." The scientific name of the common cork-bark elm is *ulmus fulva*. That of the pitch pine is *pinus rigida*. Both are indigenous in this State.

Synonyms of Apples, Pears, etc.—F. T. R., Ottawa Co., Ohio. You will find most of the various names by which certain varieties of fruit are known in different localities, given in Downing's late work "Fruits and Fruit Trees of America,"—a most excellent book of 760 pages, with illustrations of all the leading varieties of apples, pears, etc. (Price $1.75.)

Sweet-Sour Apples.—Since the reference to these on page 229 (August *Agriculturist*), we have had several letters from parties growing them. N. G. Abbot, Warren Co., Pa., says he has apples which are plainly Talman Sweetings on one side, and R. I. Greenings on the other. He offers no explanations of the anomaly.—M. A. Barker, of Wyoming Co., N. Y., says apples with one side sweet and the other side sour, are obtained by splitting a sweet and a sour cion, carefully tying them together and inserting at the grafting season. Even a bud on each must be split, and the two united just in the outer edge of the cleft, and be well covered with wax. This has been stated before, but so far as we can learn, no one is able to produce the "half and half" apples at pleasure. They appear to be a *lusus naturæ*, a sport of nature, not to be produced by human art with any certainty.

Seedling Apple.—From J. A. Lewis, Windham Co., Conn. Resembles Porter in size, form and color, of whiter flesh, moderately juicy, mild sub acid flavor, and apparently worthy of dissemination.

Manufactory of Flax Cotton.—We learn that Mr. Samuel C. Allen, an inventor of machinery for making flax-cotton, has recently purchased large buildings, water power, etc., in Lawrence, Mass., for the establishment of a manufactory of flax-cotton goods. It is said that the company engaged in this enterprise have abundant means; the present scarcity of cotton will certainly give great encouragement to the undertaking.

When to Gather Cotton.—O. C. Wilson, Williamson Co., Ill. The practice at the South is to commence picking as soon as enough bolls are open to keep the field hands profitably employed. The character of the staple is injured by much exposure to rain, and a heavy storm often causes much difficulty in the picking by tangling the fiber with the burr. Northern grown cotton will need to be picked early, perhaps while the seeds are yet green, which will do no harm, provided it is afterward dried in the sun. It should, under all circumstances, be dried of dew and rain before storing.

Missouri Corn—Housing Stock, etc.—Wm. Russell, of Iron Co., Mo., planted corn on timothy sod, heavily surface manured, dropping 2 kernels at each step 1½ to 2 feet apart, and covering with the foot. Rows 3½ feet apart. Went over each row with 2 horse harrow, having front tooth out, which left the surface light. Followed in 2 weeks with shovel plow, which was all the cultivation given. There were no weeds to trouble the crop. At harvest he found a heavy yield, with 1 to 2 ears on every stalk. He cuts his stalks with a power cutter, and feeds out during the winter. His cattle are regularly housed in cold weather which he thinks more than pays in the diminished food they consume, besides saving the manure which would be lost were they running at large.

Fall Pippins kept until Spring.—M. L. Goff, of Brooklyn, N. Y., writes to the *American Agriculturist*, that last year he bought a barrel of Fall pippins (not winter apples) in the market, and sorted them over into three lots: those perfectly sound; those slightly bruised; and those mellow—throwing the decayed ones aside. They were then all wiped dry with a towel and wrapped separately in pieces of newspaper. They were then packed into an old cheap trunk, the soundest on the bottom and the mellowest at the top, and the trunk set into a small dark closet off from a room seldom warmed in winter. At New Year's a few were taken out and found as good as when put in, and from then until the *last* of April they were occasionally drawn upon, all remaining entirely sound. The last dozen or so were a little shriveled, but still very good.

Working Orchard Lands.—William Ralston, Guernsey Co., Ohio. Moderate cropping rather benefits than injures orchards, provided plenty of manure be supplied, and proper care be taken not to injure the trunks and roots of the trees. A heavy sward excludes air, and is unfavorable to rapid growth or full fruiting. Hoed crops are generally preferable for orchard culture.

Seedling Pears.—C. S. Rust, Oswego Co., N. Y. The pears sent us are undoubtedly seedlings. They appear to be worthy of dissemination among the really good pears, and are therefore entitled to a name.

Test of a Grape.—Mr. G. R. Garretson, seedsman of Queens Co., N. Y., says: a *good* grape is one whose skin we can eat, and whose seeds can be spit out.

Evergreen Vine to Cover a Stump Fence.—C. A. Hindes, Allegany Co., N. Y. The European Ivy is the most suitable evergreen climber to cover the unsightly roots of your fence, and the Holly or Mahonia is the best shrub to fill the vacant spaces. Covered thus, with the evergreen Mahonia to fill gaps, the fence will be quite ornamental.

Lead and Copper Wire.—Lead wire is much used in England for tying up fruit trees and vines to stakes and trellises, also for attaching labels to stakes. It is soft, flexible, durable, and less hurtful to plants than copper wire. It is made of lead and an alloy mixed with it. For the coarser uses of gardening, especially where much strength is required, this is undoubtedly a good thing. Yet for common, every day work, such as tying plants to stakes, etc., we much prefer the old bass matting. This is cheaper, more easily handled, and sufficiently durable.

Second Crop of Hubbard Squashes.—A subscriber in Lamartine, Wis., in a note dated early in September, said: "A Hubbard Squash vine on which seven squashes have ripened, has now a second crop as large as goose eggs. The vine was well shortened-in early in the season."

Coal Tar on Cabbages.—"C. C.," of Jamesburg, N. J., referring to the experience of A. P., page 263, (Sept.), says that if he had diluted the coal tar with water before using, a tablespoonful of tar to a pint of water, it would not have injured his cabbages, but would have kept the slug from them. He "knows it, for he has tried it."

Value of Sunflower Seeds.—E. J., Millville, Pa. Sunflower seeds contain a large amount of oil, which may be expressed and used for burning and other purposes. They are very valuable as feed for poultry, being worth probably as much per bushel as corn.

Bouvardia.—G. T. Rockingham Co., N. H. This evergreen shrub requires the protection of a greenhouse or flower pit, in Winter. It does well for a border plant in Summer. Bouvardia *triphylla* with bright scarlet flowers is the more common variety. They are renewed by cuttings, generally of the roots.

Keeping Geraniums, Verbenas, Heliotropes, etc., through the Winter.—"L. H. R.," Rock Bottom, Mass. A green-house or pit, such as is described on page 273, Sept. *Agriculturist*, is the best place for these plants during winter. They can be kept in a cellar, but will require some care, giving them just enough water for moisture without causing them to mold or damp off.

Flowering the Camellia.—E. S. Bartholomew, Chautauqua Co., N. Y. Repot soon after they are done blooming, which is usually in February and March. Moist recommends as soil for potting: 3 parts loam, 2 parts leaf mold, and 1 part each of sand and well rotted manure. Keep the plants now in pots in moderately cool moist rooms (parlors and living rooms are too dry) until December, when they may be carried to the warmer apartments to prepare them for blooming. Water and syringe them frequently. Eight inch pots are large enough for blooming.

Japan Lilies.—M. T. Scott, Franklin Co., Ohio. These are very pretty, and perfectly hardy. Most florists and seedsmen now have them on sale at 25c. to 37c. per bulb. They may be planted in the Fall or Spring.

Dahlias Changing.—"Ignoramus," as he calls himself, of Bloomfield, N. J., says he purchased choice dahlia roots, and planted with care in 1859. They were put in the cellar the next Winter, and planted out the following Spring, but he was surprised to find the blooms had changed color, and now he can hardly find one like the original in the whole collection. He wishes to know whether others have found the same trouble.

Flower Seeds from Colorado, which have failed, were probably killed with kindness and too much water, says J. B. W.

Bladder Nut (*Staphylea trifolia*), is the name of the shrub sent by R. B. Griffith, Grand Isle Co., Vt. It is a native of the northern States, generally found in moist shady places. Its inflated capsules are quite showy.

Growing Plantsin Moss.—This is nowa-days put forth as something new; but we learn from Phil. Transac. Abridg., Vol. 10, p. 796, that it was done by C. Bonnet, of Geneva, in 1745. He grew successfully, wheat, barley, peas, pinks, daisies, tulips, and cuttings and layers of vines.

Double Crocus.—"Horticola." We have never seen it, but have read of such a thing. Clusius, an old author, speaks of the "crocus, vernus, latifolius, flavo-vario flore duplici, the double cloth of gold crocus." Sabine says that some consider this only a sport, but he is satisfied that the double-flowering bulb has appeared. In the *Hortus Floridus*, we find two crocuses figured, one of which is described: "crocus pleno aureo flore striato." When we are so lucky as to find two double crocuses, "Horticola" shall have one of them.

What ails my Verbenas?—"Jennie," of Brooklyn. We can not tell you positively without knowing more about the case. In some places, verbenas suffer from a species of mildew or rust; in others, from minute insects. We suspect *your* trouble arises from setting your plants in the same bed every year. Experience shows that they will thrive best in soils renewed every second year. Let the soil be light and poor, rather than heavy and rich.

The Botanist Douglass.—"Amateur" inquires from whom the fine spruce-fir, *Abies Douglassii*, was named? It was from Mr. Douglass, the botanist and indefatigable plant collector. He traversed many portions of the world in search of new trees, plants and seeds. It is even said that he has enriched England with more varieties than any other traveler. We are indebted to him, among other things, for a fine Spirea, for the elegant Clarkia, different species of Pentstemons, Lupins, Œnotheras, Gesnerias, Ribeses, the Spruce already named, also Pinus Lambertiana, Pinus Douglassii, etc., etc. He traveled up and down our Pacific coast, in South America, and in the Sandwich Islands. It was in the latter country that he met his death, and that in a most melancholy way. In roaming among the mountains he fell into one of the pits dug by the natives for the purpose of catching wild bulls. One of these animals was in the pit when he fell into it, and gored him so dreadfully as to cause his death.

Egg Plant Made Palatable.—We have just learned to eat egg plant with pleasure, and perhaps now it is more the fixings than the plant itself. It certainly tastes well cooked thus: Cut in thin slices; dip these in (hen's) egg beaten; sprinkle on powdered cracker, and fry with as little grease as possible.—After eating them awhile in this very palatable form, we may come to like them pure and simple.

The Largest Cheese.—W. Whitford, alluding to the cheese spoken of in the September *Agriculturist*, says it was probably the one made in Cheshire, Mass., and sent to Thos. Jefferson, while he was President of the United States, 61 years ago. Mr. W., who by the way is now 81 years of age, recollects the cheese well, as it was pressed in his uncle's cider mill; it was four feet in diameter, and weighed 1,300 pounds.

A Large Cheese.—It is reported that a dairy firm, Messrs. Steele & Bro., owning seven hundred cows, near San Francisco, Cal., made a cheese weighing 1,779 lbs., which sold for 25 cts. per pound in San Francisco, amounting to the round sum of $444.75!

Metheglin.—E. S. Locke, Warren Co., Ohio. Metheglin is honey and water boiled and fermented, and sometimes flavored with spices. We do not know the particulars for making it, and find nothing in the cooks.

Red Ants in the House.—G. Bassler, Butler Co., Pa. Another subscriber says he has "well nigh exterminated these rebels by persistent efforts in feeding fresh meat followed by hot water baths, scalding whole regiments at once." Dishes of sweetened water set in different parts of the house will assist in their destruction. Sponges baited with sugar become filled with them, when they may be scalded out in hot water.

Coffee.—Mrs. J. Shirk, of Parke Co., Ind. The coffee of commerce will not grow at the north, except in glass-houses. The Illinois kind you speak of is bogus—it is only a sort of *pea*. We paid 2c. each for 50 kernels sent by mail, just to prove what we suspected, viz.: that they were the "chick pea."

"Turn to the Left."—Dr. J. S. Shimer, Lehigh Co., Pa., accounts for the rule in this country, requiring teams to turn to the right, as follows: When heavy four and six horse teams were chiefly used, the driver either rode the saddle horse or walked beside him on the left side. This would make it more convenient for him to keep to the right, in order to avoid collision. He says that drivers of two horse teams almost universally occupy the left of the seat, and hence can better turn to the right.—In N. Y. State the custom of drivers is the reverse; they sit on the right hand, but continue to turn to the right. Either the seat, or the direction of turning should be changed.

Steam Fire-Engines.—These are rapidly superseding the hand-engines, both in this and other cities. At a large fire, within two blocks of the *Agriculturist* Office, we noticed six steam-engines throwing their powerful streams into the fifth and sixth story windows. The fire was kept from spreading beyond three or four buildings where it originated, which could not have been done with the hand-engines. One who has worked at the brakes of a hand-engine until nearly exhausted could not but look upon these muscle-saving machines with a feeling of relief as, hour by hour, under a broiling sun, they poured enormous streams of water without cessation into the burning buildings.

Origin of Fires in New-York.—From the Fire Marshal's report, we find that for the six months ending first of June, there were 185 fires in this city, the principal of which were caused by the following, viz: defective stoves and pipes, 25; gas leakages, and gas in windows igniting curtains or goods, 21; carelessness with lights, 20; sparks on roofs, 11; defective chimney flues, 10; grates, fire places, and fire boards, 9; furnaces, 8; children playing with fire or lights, 8; intoxication, matches, steam boilers, and hot-air registers, 6 each.

Dried Fruit for Soldiers.

This matter, first proposed in the *American Agriculturist*, last month, is meeting with a general response. The subject was laid before the Sanitary Commission at Washington, and Secretary Olmstead immediately telegraphed, not only here, but to the press of the country generally, that dried fruits would be most acceptable, and, that too many could not be provided. Imagine the home table spread three times a day with nothing but soldiers' rations, (mainly bread and meat), and every one can judge how acceptable would be a dish of dried apples, or peaches, even if stewed in water only. Most camps are supplied with sugar, however. We repeat, that all parcels sent to the office of the *American Agriculturist*, will be forwarded hence without further expense. Mr. Lilienthal, who has an immense tobacco manufactory, generously volunteers to detail a sufficient number of his employees to repack all fruit sent here, to do all the necessary carting, and to provide for the expense of forwarding from this city to Washington and other points. As a general rule, however, it may be well to send fruit direct to some favorite regiment. The Express Companies will carry such parcels cheaply. Any surplus, after providing for your own regiments, please forward for those soldiers who have no country fruit-growing friends to look out for them. Let the fruit be well dried, so that it will keep well (but do not crisp it by the fire). Probably it will keep best in small bags or parcels, packing these into large bags or barrels for transportation. Let the "paring bees," and the evening home circles employ many active hands in preparing dried fruit for the noble soldiers.

P. S.—Since the above was put in type, Mr. Lilienthal has called to say that he has extensive lofts, suitable for drying apples by steam heat, with a large number of employees whom he can set to work, and he will be happy to prepare and dry, at his own expense, any surplus fruit which others are willing to contribute, and which they cannot attend to themselves before it would decay. We trust that this proposition will be freely responded to, and that a very large amount may be contributed. We know Mr. L. to be the man to carry out anything he undertakes. Those sending fruit will, of course, deliver it here free of expense for freight and cartage. Better send it direct to his principal office, No. 217 Washington-street, (west of the City Hall.) Acknowledgment of all fruit received will be made to the senders.—It is proper to state that Mr. L. requested that his name might not appear in this matter, but to have it done privately, or through the *Agriculturist* Office. We thought it necessary, however, to the success of the enterprise, to state who is at the head of it. Were we at liberty to do so, we could tell of very large contributions for the comfort of the soldiers, made by Mr. L. since the war commenced. We only refer to the matter, in this connection, to incite others to co-operate with him in this well-timed endeavor to contribute to the pleasure of those who are so nobly fighting our battles for us.

Notes on the Breadstuff Markets.

Columns of figures are not usually very interesting reading, but the condensed tables and the list of prices current now and one month ago, given in the Market Review of the *American Agriculturist* (page 347) will attract the attention of farmers, and even of the general reader. In table 1, it will be seen that the *receipts* of wheat for 23 business days, ending October 18, amounted to 5,079,000 bushels, against 3,270,000 bushels for the 26 previous days; or allowing 215,000 bushels for the less receipts of flour, the increase is still equivalent to more than a million and a half bushels of wheat, with one day's less transactions. The increased receipts of corn, barley and oats are correspondingly large. The *sales* of wheat have been over a million bushels greater, and of flour twenty eight thousand barrels greater. The *exports* of breadstuffs for three years, given in table 3, are the most important features of the market. It will be seen that unprecedently large as they were last year, they have been still greater during the first 9¼ months of this year. During that period this year, we *exported* from this city: of wheat, 19,097,373 bushels; last year 18,642,887 bushels; and the previous year only 8,101,018 bushels. Of flour, we exported this year 2,436,328 barrels; last year 2,121,403 barrels; and the previous year 1,340,981 barrels. Of corn we exported this year 9,228,402 bushels; last year 9,380,595 bushels; the previous year only 2,170,894 bushels. Of rye, we exported this year 1,060,018 bushels; last year 501,795 bushels, and the previous year barely 450 bushels. These figures, and the fact that the export demand at this moment is as great as ever, confirms what we have insisted upon for some time past, viz.: that there is again this year a material deficiency in the cereal crops of Great Britain and the rest of Europe. In the London journals, up to the harvest season, and in our conversations with the leading dealers of that city, it was constantly held out that their greater area of growing wheat, and the constantly *expected* favorable weather, would give them at least an average crop. Our personal observation of the actual condition of the growing grain, and information from many private sources, led us decidedly to the contrary opinion, as we informed our readers at the time.

The table of prices current now, and a month ago, show a very large advance in wheat and flour, and considerable advance in corn. Thus: State flour has risen from an average of $5.40 per barrel last month, to an average now of $6.65—equivalent to an advance of over twenty three per cent. Other brands have similarly advanced. All brands of white wheat have risen from an average of $1.44 per bushel to an average of $1.55. All kinds of red wheat, from an average of $1.20 to an average of $1.33½ per bushel. Corn (mixed) from an average of 57 cents to an average of 64½ cents. The benefit to farmers of the increase in exports, and the advance in prices is discussed elsewhere.

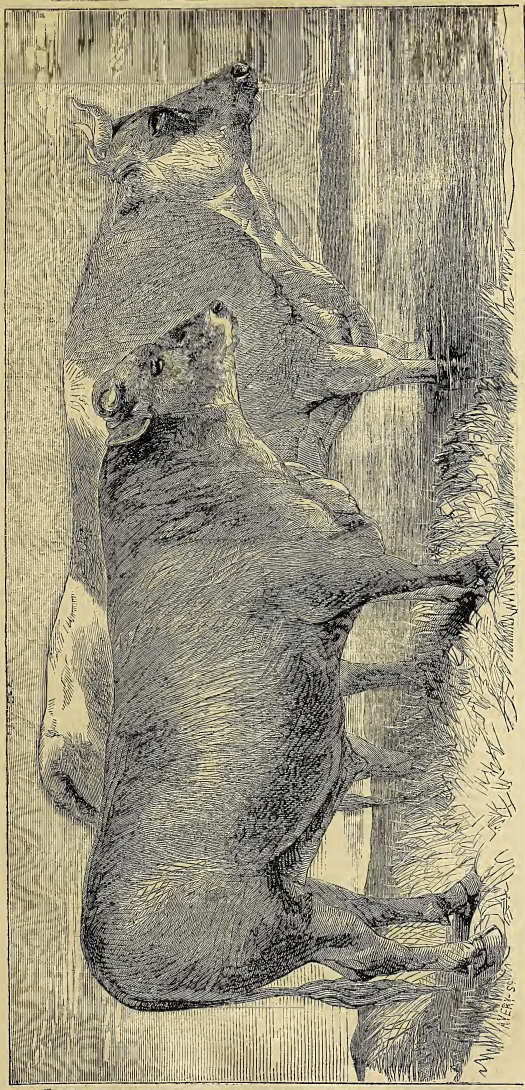
The Rise in the Value of Gold, and its Effects upon Farmers.

One of the marked events of the month is the rise in the value of gold, as compared with the legal tender currency of the country. At the time of this writing, gold is quoted at $132—that is, $100 in American gold coin will buy $132 of bank notes, or United States Treasury Notes, either of which pass current in trade or in the payment of debts at their par value. Any one having $100 in gold can buy 100 bushels of wheat of a grade quoted in the market at $1.32 per bushel. Or, *vice versa*, a farmer having 100 bushels of wheat which in a foreign market would buy only $100 in gold and enough more to pay the expenses and profits of export, can sell it for $132 of a currency that will pay his debts to the merchant, or on his farm. Again, suppose a London grain dealer, whose purchases are on the gold basis, desires to procure 10,000 bushels of first grade wheat. In his own country or elsewhere in Europe, he must pay, say $1.50 per bushel, or $15,000. The same grade of wheat is quoted in New-York at, say $1.60 per bushel. Add 20 cents per bushel for freight, insurance, and other expenses, and the 10,000 bushels of wheat would cost him delivered in London $1.80 per bushel, or $18,000 in all. But his $15,000 sent in gold, or laid out in exchange, would buy in New-York $19,800 of the par currency, from which he could pay $18.000 for the 10,000 bushels of wheat at $1.60 per bushel and $2,000 for expenses, and yet save $1,800. The same reasoning applies to other articles of export—flour, corn, provisions, etc.

These figures, though not representing exactly the actual difference in prices, are a fair illustration of the effects upon our breadstuffs and provision markets, of the recent rise in the value of gold as compared with the legal currency of this country. The exporting of grain and provisions has been greatly stimulated, and shipments abroad have gone up to unprecedented figures, as detailed in another article.

We are not discussing the advantage or the disadvantage of this disturbance of the currency of the country. The country at large is not any richer because a hundred million bushels of wheat are represented by a hundred and thirty two million dollars of legal currency instead of one hundred million gold dollars, for the real value of the two are the same. The particular point we are here aiming at, is, to show that this great advance in gold is inuring to the special benefit of farmers, even doubly so. *First*, it has created a greater foreign demand for our produce, as illustrated above, thus enlarging the market as well as increasing the prices. *Second*, the greater prices Farmers receive for their grain, butter, meat, etc., though not in gold, are in a currency that is a legal and acceptable tender in the payment of their debts to merchants, their land debts, etc. The nominal rise during the past month, of 10 to 20 cents per bushel in wheat, of $1.20 to $1.30 per barrel in flour, of 8 cents per bushel in corn, of 2 to 4 cents per bushel in oats, of 4 cents per pound in butter, etc., is so much clear gain to farmers, in the payment of debts previously contracted. But the rise in articles which farmers must buy, is nearly equal to the advance in what they have to sell, and more, on some articles. (The price of the *American Agriculturist* is about the only thing that has not gone up lately.) The advance in sugar, coffee, cotton and other cloths, however, is due more to the high tariff, taxes, and other causes growing out of the war, than to the advance in gold, and nearly the same prices would have prevailed had not farm products gone upward. It is evident, therefore, that however unfavorably others may be affected by the present disturbance in the currency of the country, farmers are clearly the gainers.

The practical lesson we would impress upon farmers is, that they should improve the present opportunity to pay off their liabilities, and get upon safe ground. Because their products can be sold at higher figures than formerly, they should not increase their outlay by more expensive living, by running in debt for dress or carriages, or for more land. Debts contracted now, may have to be paid when money is of comparatively greater value—when a bushel of grain, or a pound of butter will buy much less money. Better take in sail, and be ready for any storm that may suddenly come. Stick to the old coat, and hat, and carriage. A cheaper dress will suffice for a year or two. Patch up the old dwelling, it will keep the family comfortable a year or two longer. Put in a few extra acres, or rather provide for better cultivation of those already planned for. The inflation of the currency *may* continue a year or two yet, in which case products will continue to yield large nominal returns in the market. When they fall, you will need the more of them to sell. A financial pressure must come, when values return to the gold standard. The change may be gradual and extend over years, and not all at once, in a crash and smash. The farmer who is then out of debt, and can raise from his own soil crops enough to supply his actual necessities—his bread and home-produced clothing—will be able to look out serenely upon the financial storm around him. The summing up of our discourse is: Now is the time for farmers to get out and keep out of DEBT.



SWISS CATTLE.—PRIZE ANIMALS AT THE ROYAL AGRICULTURAL SOCIETY'S SHOW, LONDON, JUNE, 1863
(Engraved for the American Agriculturist.)

Swiss Cattle.

The annexed engraving is designed to represent two Prize Animals we saw on Exhibition at the late show of the English Royal Agricultural Society. The artist has hardly done the animals justice. These improved Swiss Cattle somewhat resemble the Short-Horns, though rather larger boned, and not yet fully developed in some of the "points." Intelligent Swiss breeders are making constant improvements however, and several experienced men with whom we conversed, both in Switzerland and Germany, consider them, in their present condition, as better adapted to Switzerland, and to Central Europe generally, than any of the breeds so highly esteemed in England. Prof. Rau, of the Hohenheim Agricultural College, Wurtemberg, has a large herd of pure Swiss Cattle, which he is breeding for dissemination in that kingdom, as he considers them best adapted to that country. The pure-bred Swiss cattle are of large size, medium boned, hardy, and will thrive on pastures too poor for the Short-Horn. They are good milkers withal, and we are not certain that they would not be found admirably adapted to many parts of this country. We threw out this hint to Mr. Thorne, and other public-spirited breeders, who have already done so much for the improvement of our stock. We may add, by the way, that at the Battersea Park Show the Swiss cattle attracted more attention from the curious multitude, than any other class of animals—except perhaps a pen of shaggy ponies, direct from Shetland. Each Swiss cow was supplied with a *large* sweet-toned bell, such as is worn by every cow in their native land. Nothing among Switzerland scenery was more interesting to us than to listen to the sound of these bells, heard upon the mountain sides at the distance of two or three miles, on a still evening.

Milch Cows in Fall and Winter.

Milking, except for a short period after the birth of a calf, is altogether an artificial process. Nature intended animals to yield milk only while it should be necessary for the sustenance of the young; but by long training, artificial habits have been induced, and the flow of milk is prolonged for months, and even for years, after the natural period has passed. Partly for this reason, no secretion of the cow is more easily affected by treatment of the animal. Any derangement of health, insufficient food, or bodily discomfort, at once shows its effects in the decreased quantity and quality of the milk. It should also be borne in mind that the continued flow of milk beyond the natural period is no small drain upon the vital functions of an animal, and this should be counterbalanced by extra stimulus in the form of good nourishing food, and whatever care is necessary to keep up the health of the cow to the highest standard.

At this season of the year change of food is necessary. Long before the pastures are entirely despoiled of verdure, the grasses nipped by repeated frosts lose much of their nutriment. Though cows may gather their fill, it is of poorer quality, and the yield of milk speedily suffers. A daily allowance of bran, shorts, or ground feed of rye and oats, or two thirds oats with one third corn, will supply the lack of nourishment, and show itself, with good interest added, in the milk pail. This feed should be wet before using. We prefer it to feeding with hay, for the reason that nourishment, more than bulk, is needed; they can pick up enough part-

ly withered grass to fill their stomachs. This extra allowance should not be delayed until the animal is suffering from insufficient food. It is far easier to keep a cow in good condition, than to bring her up after falling off.

Pumpkins are usually fed out first, upon failure of the pastures. If it be practicable to keep them uninjured until later in the season, it would be better. They come in best when dry hay and stalks are the staple diet, and something more succulent is craved and needed. It is best to remove seeds from pumpkins; they are an active diuretic, and many believe that they divert to urine fluids which would form milk.

Any person who has been long confined to a single article or two of food, say to salt beef and potatoes, knows how the appetite craves a change. The greediness with which cows lay hold of turnips, mangel wurzels, or other roots in Winter, proves that they, too, relish variety, and in the case of healthy animals, appetite is a safe guide in the selection of food. Even if roots were lacking in nutriment, an occasional allowance of them to cattle would be beneficial.

Observe strict regularity in the time of feeding. If meals are regularly served, animals will patiently wait the appointed time; otherwise, they will be restless and uneasy while looking for supplies, and ravenous when fed.

The importance of comfortable, well ventilated shelter for milch cows is yet greatly underrated, despite all that has been written and said. A large part of the food eaten is consumed in furnishing warmth to the animal. Thus, good shelter is equivalent to a large percentage of food. Besides the actual loss of food from the increased amount required under exposure to cold, there is further loss in milk from the feeling of discomfort. The secretions are always disturbed by influences that cause pain or uneasiness, and every shiver of a half-frozen cow will make itself visible in the milk pail.

In their anxiety to secure warmth, many have overlooked the importance of pure air. Close, crowded stables, reeking with odors from accumulating manure, produce feverish restlessness in the cows, and the flow of milk suffers. At best, confinement during the winter months is irksome to animals, and kindness to brutes, as well as profit, demands that everything practicable should be done to secure their comfort.

For the American Agriculturist.

Feed for Farm Horses.

When I was a boy in the north of Vermont, we used to feed dry hay and oats, unless the horse had the heaves, which was very common among them at that time, owing to feeding too much dry hay and oats, and driving too fast when full. We then supposed they ought to have hay before them all the time. This is a false idea; all kinds of animals will do better on regular meals. Farmers usually feed too much dry hay. You may keep a horse eating all the time and not have it thrive. I came to Massachusetts about 12 years ago, and was engaged in the teaming business about 7 years. I began to feed cut hay and corn meal, and found the horses would do more work and last longer, and be in better condition than when kept on dry feed. Cracked corn and oats make a very good feed for noon, when in a hurry. I would feed carrots all winter in small quantities, especially to young horses and breeding mares. This keeps them in a healthy condition. Team horses may be fed on them once each day to advantage. I am not able to state the amount each horse should be fed: this depends on the size and age of the animal. I would advise all owners to keep their horses, especially those they use, in good condition; it costs less in the end. Colts ought not to have much grain, unless very thin in flesh; they are often injured by graining. A few ground oats, with cut hay or straw wet and mixed, and half a pint of ashes added once in two or three weeks, is all colts need besides hay. The ashes keep the bowels open, and, it is said, free from worms. If living in Maine or Vermont where hay and oats are cheap, I would have the oats ground, and cut a portion of my hay and straw to mix with what grain I fed, and consider myself well paid for the time and trouble. W. R. LEWIS.

Milford, Mass.

Keep Sheep.

Perhaps this counsel is supererogatory just at this time. All wool-growers and their neighbors are fully aware that at present prices, few if any other branches of agricultural industry are more remunerative. The unprecedented demand for woolen goods consequent upon the necessities of the immense armies now in the field and being raised, is still further enhanced by the scarcity of cotton, which brings woolen fabrics into more general use. How long this exceptional state of things may continue, it is impossible to predict with certainty, but there is good reason to suppose that even if the long-wished for peace should be proclaimed within the next six months, the demand for woolens will almost certainly be such as to give a paying return for investment in sheep. One fact alone speaks volumes in favor of sheep-raising. There has been imported into the United States from foreign countries, wool and woolen goods to the average amount of $35,000,000 to $45,000,000 for the last three years, equivalent to the yield of at least 13,000,000 sheep. It is stated by Daniel Needham, Secretary of the Vermont Wool-Growers' Convention, that the average annual increase of population in this country requires the wool of 3,000,000 sheep. If these figures be only approximately correct, they demonstrate the slight danger of an overstock of sheep for many years to come. The present and prospective high tariff will keep up the price of American-grown wool to much higher figures than have prevailed hitherto.

The scarcity of mutton has, as would be expected, been aggravated by the rise in wool. We say aggravated, because year by year before the breaking out of the war, it had been more and more difficult to procure a supply of good mutton at reasonable prices. At present this article is one of the luxuries. Very wisely, few care to sell when prospects for keeping are so good. Even if the wool market should return to its ordinary level, or below it, there is abundant encouragement for sheep-raising.

Of course, each must be governed by the circumstances of his locality, both in deciding to invest in sheep, and also as to the best breeds. Thus, the average cost per head, per annum, of keeping sheep, is estimated as follows: In Illinois, 60 cents; Iowa, 75c.; Michigan, 83c.; Virginia, 60c.; New-Jersey, 60c.; Pennsylvania, 50c.; Maine, $1; California, 75c.; Vermont, $1.30.

In Vermont, after trying almost every breed, the majority of wool-growers give the preference to the Spanish Merino, as yielding the largest return for wool. Where mutton is the principal object, as in the vicinity of large cities, larger middle-wooled breeds, like the Southdown, are preferable. The latter breed probably combine the desiderata of both wool and mutton in a higher degree than any other raised in this country. With the additional security which the tax upon dogs will give, we may safely say the prospects of the sheep interest in this country are better than ever before. A word to the wise is sufficient.

A Good Breeding Ram.

In answer to the question, "What ram shall I choose?" a correspondent of the Mark Lane Express (England), writes, "Take care that in every case you select an animal of like contour of frame, *i. e.*: full and proportionate throughout. To be more minute: His head should be masculine, but denoting kindliness; his neck full and of fair length—not a thick, short, bull-neck, but kind and graceful; his shoulders, chine, and chest, all wide and full in form, the chine joining nicely to the neck, the breast end out, the brisket wide and fat; the ribs well springing and nicely arched; the back and loin level and broad, and fully covered with firm fat and muscle; the hips wide, rump rather long, but full, and not hanging; dock thick and fat; twist wide and well filled; purse well hung, and covered, not too long nor large; legs and flanks thick and full; offal fine but not light; wool good in quality, and as much of it as can be got. The breeder that obtains all these points in perfection is worthy of all credit; but be that as it may, he must seek to obtain them in as great a degree as possible; of course, the more of these valuable points he gets, the better."

For the American Agriculturist.

Rearing and Fattening Hogs.

BY SAMUEL BERRIMAN, OF STAMFORD, C. W.

[The following article was submitted in competition for the prize, and though not awarded a premium, it contains too many practical hints to be left unpublished.—ED.]

The writer has been a breeder of hogs for the last twelve years. The breeds raised have been: Byfield, Suffolk, and improved Berkshire. I prefer the latter, after much experience, for the following reasons, viz.: They breed equally well with the others, fatten earlier, and command a higher price in the market. It is acknowledged that the cost of wintering hogs is one of the greatest difficulties in raising pork; hence a change of breed to one wherein the weight can be attained in half the time, and at two thirds the cost, will be a marked advantage.

The gain derived from raising and feeding improved hogs will readily be seen, when it is borne in mind that the weight usually attained by common hogs kept over winter, is not greater than the ten months improved breeds. Again, for example, what will be the gain in weight on the first day of May, of a four-month's hog weighing sixty to seventy pounds on the first day of December previous, fed and cared for in the ordinary way? This question I have put to many farmers, most of whom admit that such gain is small; others say that such hogs will do well, if they hold their own during the winter. Now if this gain in weight is so small, what is the cost of such gain, or of holding their own?

It would be far better to save the food used in winter, and apply it towards the fattening of Spring pigs early in the Fall. I keep none but breeding sows during Winter. My practice is, to have my sows come in as near the middle of February as possible. The sows and pigs are kept in a warm, comfortable sty, well protected from the prevailing winds. The sow is supplied

with as much corn meal, mixed with skimmed milk or dishwashings, as she can consume during the time the pigs remain with her. The young pigs remain with the sow eight weeks, when the sow is removed and runs at large. The pigs are fed with skimmed milk and dry corn meal, in separate troughs, until there is a good covering of clover on the ground, when they are put into pasture, and the milk and meal gradually reduced. After about a month they will be quite able to live and thrive under the same treatment as the older ones—that is to say, clover as the staple article of food, with such a supply of skimmed milk and dishwashings as the house may afford.

The sows are allowed to have another litter during Summer, which are either used in the family as roasters, or sold for store hogs. Early in September the hogs are taken up and put into pens—say about six in each; potatoes and other vegetables are steamed and mixed with the skimmed milk, etc., from the house, along with a small quantity of ground screenings of grain, or ground barley, and fed three times a day. This course is continued about six weeks; the quantity of ground barley or screenings is then gradually increased, and the steamed potatoes and vegetables decreased until the middle of November, when corn meal, mixed with such a quantity of skimmed milk or dishwashings as may be necessary to make it moderately moist, is substituted until the middle of December, at which time the hogs are slaughtered. In this way hogs are brought to weigh over three hundred pounds at the age of about ten months.

The hams and shoulders are then cured thus: A mixture of one fourth brown sugar to three fourths dry salt is made; the hams and shoulders being placed in a large salting tub (water and brine proof), the skin side downwards, are then covered with the above mixture of salt and sugar, say a third of an inch thick, a little salt and sugar being applied from time to time on such portions of the meat as become uncovered by the formation of brine—particular care being taken to keep the meat well covered near the bone. The hams and shoulders from hogs of about three hundred pounds require to remain in the tub under this treatment, about three weeks. They are then hung up in a dry room, for a week, afterward put into the smoke house and smoked with corn cobs for a month. They are then sewed in cottou bags and lime-washed. Thus secured, there is no difficulty in their keeping good for twelve months. Hams and shoulders cured as above, are always saleable at top prices for family use. No distant market is necessary, the demand of the immediate neighborhood being always greater than the supply.

In regard to the side meat, the first care is to have clean, sweet barrels. Each side being cut into three pieces, is packed thus: the bottom of the barrel is covered with salt about an inch thick; the flesh side of the pork is then covered with a thin coat of salt and packed as closely as possible in the barrel; between each layer of meat about half an inch of salt is applied. When filled, the top receives a similar coat of half an inch of salt, and the barrel is then headed up. Meat thus cured from hogs fatted as described, brings a full price here, and is always saleable.

Pigs dropped about the middle of February, will be ready to take off from the sow about the time when most cows are coming in, and the farmer is thus enabled to give them a plentiful supply of milk. They are fat when taken from the sow and thus are kept fat. The meat while heavy, is young and tender, and a preference is always given to such pork in every market.

Query.—Is it profitable to raise hogs in any of the Eastern or middle States?

For the American Agriculturist.

Will it Pay to Winter Turkies.

The great seasons for the sale of poultry are Thanksgiving and Christmas, and then the market is abundantly supplied, and prices rule low. Farmers are anxious to sell their fowls to get rid of the expense of keeping them through the Winter, when their appetites are ravenous, and the corn and boiled potatoes disappear rapidly. It is clear it will cost something to keep them; it may not be so clear that it will pay. A little transaction of my own, last Wiuter, may throw some light upon this question. I bought a flock of twelve turkeys—the mother bird, and eleven young ones—the last of August, the average live weight of the young being about two pounds apiece. They were killed along as wanted in the family from November to March, and the monthly gain in weight was about two pounds and a half for the hens, and three pounds for the gobblers. They gained quite as much in Winter, as in the Fall, living upon corn, oats, boiled potatoes, and having access to the pigs' troughs. The number of males was six, and the weight of the mother ten pounds. The market price of turkeys was eight cents, in November, and thirteen in February. Had they all been killed November 1st, they would have weighed about 93 pounds, and come to $7.44. Had they all been kept to the 1st of March, they would have weighed about 215 pounds, and come to $27.95. The double gain, in weight and price, is an important consideration. The gain in weight was more rapid than I had supposed, before applying the steelyards.

The experiment furnishes a useful hint to farmers, and to villagers. If prices are not satisfactory, it will pay to hold on, and keep feeding poultry. The growth, and the increased price, in mid-winter and Spring, will pay for feed and leave a handsome profit, I think.

I find it difficult to raise turkeys, on account of my own and my neighbors' gardens. But the garden is out of the way by the 1st of September, and a late brood of turkeys bought of a farmer, will do no damage. They are about as easily managed as a hen and chickens, and give a great deal of satisfaction, where there is room for them. They are beautiful to look at while growing, and they make roast turkey cheap and easy to a good many who do not know exactly how to pay the common market price for the luxury. This is an item of household economy worth looking at by those who have only an acre or two of land. So thinks JONATHAN.

For the American Agriculturist.

Saw-Dust for Stables.

One of the papers reports Dr. Dadd as objecting to the use of dry saw-dust as a litter for stabled horses, on the ground that it absorbs the natural and healthy moisture from the hoof, and renders it brittle and dry, and so leads on to cracked and contracted feet, to corns and similar diseases. I had supposed this "eminent veterinarian" too sensible to hold such an opinion.

If the pores of a horse's foot were open and coarse, say like a piece of sugar or a sponge, the saw-dust might absorb moisture from them injuriously. If I lay a sponge on my hand, it does not take up its moisture. If I spread saw-dust on my hand, it will absorb whatever perspiration or other wetness there may be on the skin, but it will do nothing more. So saw-dust will take up whatever liquid manure there may chance to be on the floor of the stable, but it will not suck moisture out of the horse's hoofs. In my own practice, I have long used saw-dust to keep the horses' feet moist, though I do not, for this purpose, use the dust in a *dry* state. I spread it over the entire floor, two inches thick, sprinkling that which is under the fore feet with water, just enough to keep it moist. The dust under the hind feet gets moistened in other ways. By this means the hoof is kept soft and moist, almost as much so as if the animal were running at large in a pasture. Of the valuable liquid manure saved in this way, I need not now speak. EXPERIENCE.

It Pays to take Care of Implements.

There is danger lest, in the hurry of work, tools large and small, will be exposed to rain and sun. When so neglected, great harm is done them. The wood-work shrinks, and cracks, and rots, and the iron work rusts and is liable to break. Such implements are disagreeable to work with, and they are continually going to decay. We believe it would be a saving of money, in the long run, to take time, even in the busiest seasons, to clean and house daily all implements of the farm and the garden.

The proper care of tools involves the painting of those which are ever exposed to the weather, such as carts, sleds, wagons, horse-rakes, etc. This may seem a trifling matter to some careless farmers, but it is one of great consequence. We wish to cite the testimony of a practical man, in the Rural New-Yorker, which is right to the point. He says: "I had a sled made in the fall of 1834, at a cost of $19.00. I have the same sled now (1861) and will warrant it to carry as large a load as when it came out of the shop. With the exception of the shoes, which are getting very thin, it seems as perfect as when new. I have not paid out fifty cents in repairs, except for painting. It has been painted twice during this time, and has not staid out doors ten nights during the whole time. In the fall of 1858, I exhibited this sled and one double wagon that had been used eight years, one hoe that had been in use 20 years, without even a new handle, and one pitch-fork that had been in use 15 years without even a new handle, at the Adams' Agricultural Fair. I did not expect a premium, but was awarded a discretionary premium. The committee on Tools pronounced them as good as new, with the exception of natural wear."

A premium wisely bestowed. And here let us repeat an important item, more than once stated in the columns of the *American Agriculturist:* A mixture of three parts lard and one of resin, melted together, is one of the best coatings for all steel or iron implements. The lard makes the resin soft, while the latter is a sure preventive against rusting. The mixture is good for plows, hoes, axes, indeed for *all* tools and implements, as well as for knives and forks packed away. The coating can be very thin.

FARMING IN AUSTRALIA.—A traveler writes to one of our papers that mahogany trees are abundant on the Swan River; that farmers are clearing up the land, and putting in crops of wheat, oats, etc., and that "the government is making roads and good *mahogany bridges!*" He adds that they have very little thunder there, and that Kangaroo flesh is abundant. Do any of our enterprising farmers wish to migrate?

Mammoth Millet.

The accompanying engraving is an exact sketch of one of a cluster of millet heads now on exhibition at the office of the *American Agriculturist.* There are larger heads, but this one is the largest we could get into our columns. The straw, including head, is 6 to 6½ feet high, strong and full of leaves, which supply a good deal of forage. The artist has not attempted to exhibit the multitude of seeds which crowd each other upon the closely clustering panicles. By counting the seeds on some of these, and estimating for the rest, we find the average number on a single head about 25,000! These samples were presented by Wm. Fullerton, Esq., of this city, who has it growing in considerable quantity at his farm near Newburgh, N. Y. He uses both the ground seed and the straw for cattle feed; both are relished, and produce good results. It thrives most luxuriantly on a bog meadow thoroughly drained. It grows slowly, and should be sowed on freshly harrowed land in good condition, so that the seeds may start at once and get ahead of the weeds. Mr. F. esteems it as one of the most profitable crops. We are happy to state that Mr. Fullerton has promised us all the seed he can spare, to be distributed among our subscribers the coming Winter.

Experience with Hungarian Millet.

J. H. Wright, of Cook Co., Ill., writes to the *American Agriculturist*: In June 1861, I harrowed 18 acres of prairie sod, until it was perfectly mellow, and sowed ½ bushel of seed per acre; then harrowed again and rolled, which I consider a very important item. I also sowed 8 acres of old land, finishing July 5th. The millet was ready for the machine September 1st, but owing to wet weather, was delayed for about three weeks, when the seed was ripe. I stacked one hundred and ten loads, estimated at eighty tuns. After having fed one third of it, I thrashed the remainder, which yielded me four hundred and fifty bushels of seed, weighing fifty six lbs. per bushel. My stock do well on the thrashed straw. The seed, being small and hard, is very difficult of digestion, and I think must injure cattle or horses if fed exclusively on it for any length of time. I should, if possible, cut it while green, when I consider it superior to any forage crop I ever raised. It will thrive on any *good* soil, and suffers but little from drouth. If well put in, it is a very sure crop. I should sow another year as soon as June 15th. I think it would be excellent for feeding green to cows in Summer.

Sorghum Culture and Manufacture.

F. A. Denny writes to the *American Agriculturist:* My mode of planting sorghum is, to prepare and cultivate the ground the same as for corn. High hazel ground is the best here, although it will grow on almost any good corn land. Black prairie soil does not make as good syrup as other soil. Plant as early as the ground is sufficiently warm, and thin to five or six stalks to the hill, keeping free from grass and weeds, until large enough to plow. About the middle of September a majority of the seeds will have turned black, and the lower part of the blades will become yellow, when it will do to commence grinding. Most people strip the cane while standing, and cut the tops down to second joint. I pressed some without stripping, which turned out as well, and saved expense. For pressing I used a common two-horse three roller upright mill, rollers ten inches in diameter, twelve inches high. I also used one of Cook's Evaporators No. 2, placed on brick work, which does much better than the rocker, as it gives more heating surface. I placed a barrel under the mill to receive the juice, and at the lower end on the outside I put in a common wooden faucet, which conveyed the juice into a spout or tube, made by plowing out about an inch square groove in a piece of 1½ inch pine, 2½ inches wide, with a strip of weatherboard nailed on top to keep out dirt. The spout conveys the juice into a barrel set in the ground close to the evaporator. The tube was protected by a bridge laid down over where the horses crossed it. I placed extra hopper-shaped sides to my evaporator, to prevent the syrup from boiling over. I use a very hot fire, and boil as fast as possible, which throws up the scum better (and makes better syrup) until it is nearly done, when I let the fire cool down a little until it is run off. A little experience will soon teach when it is done.

Cook's evaporator regulates the flow of syrup so that I can run off just as much as is cooked enough. I let in the juice next the chimney, and let out the syrup at the front end over the fire, which I think is best, as I can control the fire to prevent burning the syrup when it is too hot. I used a small portion of lime as a neutralizer while the cane was green, but it makes the syrup dark. After the cane was ripe, rapid boiling and skimming alone made very superior, light colored syrup which kept well, and retailed at the mill at 50 cts. per gallon. Others here have made syrup by a different process and with kettles, but it has not kept well. Last Fall, with a man and boy, I made about 1,400 gallons. The cane did not yield near as well as previously.

Sugar from Corn Stalks.

H. A. Sheldon of Addison Co., Vt., writes to the *American Agriculturist:* I took two stalks of Stowell's Evergreen sweet corn, of average size, after the corn had been taken off, pressed them (to one joint above the top ear) between rollers half an inch apart, and obtaining five fluid ounces juice of specific gravity 1.066. Two grains quick lime were added, and the juice was boiled, strained, and evaporated to a trifle over half a fluid ounce of rich, transparent syrup. In a former experiment not weighed, it crystallized into good sugar. As I did not probably obtain more than half the juice; and allowing two square feet of land for each stalk, the result would be 66 gallons syrup, or 300 lbs. sugar to the acre. The flavor of both sugar and molasses is much pleasanter than that from sorghum.

For the American Agriculturist.

Quick Returns in Farming.

Perhaps in no calling is capital so slow in yielding its interest as in husbandry, pursued by the old methods. This accounts for the extreme reluctance with which gentlemen of the old school make their investments in improvements. If they invest in bank stock, they are reasonably sure of seeing dividends every six months. But in farming, it takes a long while for the money to come back again. A crop of wood must grow twenty years before it can be gathered. The same amount kept at interest would have a chance to double twice. A horse does not reach his maturity under five years, and a cow must be three years old before she begins to pay her way. We have to wait nine months for the harvest of the winter grains, and three or four for the Summer crops. A merchant changes his money often, sometimes handling his entire capital four times a year, and making a handsome profit each time. Every body seems to move faster and to get rich faster than the farmer.

There is truth in these statements to a certain extent. We can not have great permanence and security in our investments, with quick returns and large profits. Yet something can be done to make the farmer's sixpence nimble, while he lays his plans for twenty years ahead. He may get much quicker returns from some kinds of stock than from others. Poultry, pork, and sheep come to early maturity, and begin to pay the same season. The hen bought to-day, begins to lay eggs to-morrow, gives chickens in a month, which make good broilers in three months. The turkey's egg of to-day is a twenty pound gobbler in six months, worth two dollars. A litter of pigs of ten or more, is worth thirty dollars at two months old. A lamb at three months is worth three dollars. These animals all yield meat for family supplies the year round, and make the farmer nearly independent of the butcher. They keep the butcher constantly in his debt, and make the dollars as well as the sixpences rather nimble.

And then the dairy business need not be very slow in bringing money. Butter, of course, goes to market every week, and is everywhere a cash article. Cheese can go off once a month, and lighten the labors of the dairy woman, while it makes heavy the purse of her husband, if he have been so lucky as to marry a woman who knows how to make a cheese. If the milk is sold there is a daily disposal of the products, and returns come in weekly or monthly.

In grazing fat cattle the returns are less frequent, but it has the advantage of being a wholesale business. Cattle bought in Spring are sold in the Fall, and generally bring profit enough to keep one comfortable through the Winter.

In the management of manure, there might be much quicker returns, especially of fish and the concentrated fertilizers. The yard manure, which is generally a year in accumulating, might be spread upon meadows both in Spring and mid-summer, and bring crops within sixty days. This is an article that can not be safely hoarded. The roots of grasses will turn it into money right early. We have sometimes spread manure in May, and seen it double the crop of hay cut early in July. We have spread it in August, and made the aftermath luxuriant for cows all through September and October. There is a great advantage in having this flush feed late in the season. It makes a full flow of milk, and the butter and cheese are nearly equal to the products of June. By this process, the manure is turned into money in a very short time. Farmers upon the shore where fish are caught, have a great advantage in having manure always accessible. We have applied fresh fish in the hill to the growing corn late in June with the best results. Manure is quite too precious an article to have it remain idle in the yard.

AN EASTERN FARMER.

For the American Agriculturist.

When to Sell Potatoes.

It is full one half of farming to know when to sell products. With many of small means the temptation is strong to sell as soon as the crop is gathered. The hay, the grain, and roots go immediately from the field to market. It saves once handling and the peril of loss from fire, rot and other causes. This makes potatoes cheaper in the fall months than at any other season of the year. Every body who raises potatoes wants to sell. The merchant who is shrewd, buys frequently of the necessitous farmer, at thirty or forty cents, and sells in the Spring at wholesale for seventy-five or eighty cents.

Any one who will trouble himself to look over the prices current of potatoes in years past, will see that the price is from fifty to a hundred per cent. higher in March and April, than in November. Five per cent. will probably pay for storage and handling. Farmers generally have ample store room for all they raise, and they may as well share the profits of the merchant. If the crop is unsound, of course the sooner it is sold and consumed the better. If in good condition, it will generally pay for keeping until prices are remunerative. CONNECTICUT.

[This depends much upon circumstances. We think five per cent. will seldom pay for risk, to say nothing of expense of storing and handling. If a farmer has had successful experience in keeping potatoes, it is generally worth while to store them. Our own observation is, that the loss from rotting, shrinkage, mice, expense of storing, and interest, averages from 25 to 30 per cent., taking the country together, in which case it would be as well to sell at 30 cents per bushel in Autumn as at 40 cents in Spring. Still, somebody must keep them, and the skillful farmer may better make the profit than any one else, if he can safely do it.—ED.]

For the American Agriculturist.

Manuring without Manure.

It often happens that a farmer wishes to manure a field or two more than his dung heap will allow. It is sometimes the case, also, that he wishes to enrich a piece of ground lying at too great distance from his barn-yard for convenient hauling of manure. What shall he do? In reference to the first, we say, if you do not wish to meddle with patent fertilizers, use muck, if your farm contains a bed of it, or if you can get it with reasonable cost of labor and money. To prepare it for use, haul it out into the middle of the field, and mix it thoroughly with ashes or lime. One hundred bushels of hard wood ashes unleached will neutralize the acids of thirty cords of muck, and this will manure two acres of land. The ashes will cost from ten to fifteen cents a bushel, and the muck if bought will cost, perhaps, fifty cents a cord delivered on the field: if found on the farm it will cost only the time and labor of digging. If this compost is made up in the fall, let it be shoveled over once or twice before using in Spring.

When ashes are not conveniently at hand, lime may be used. Take fresh, unslaked lime, mixing at the rate of half a cord of muck to a bushel of lime. Add a bushel of salt to six bushels of lime, dissolved in water enough to slake the lime finely, preparing the lime only as fast as wanted, and spreading it on fresh in layers over the muck. The layers of muck may be about six inches thick. Spread on lime enough each time to thoroughly whiten the surface. Carry up the heap about six feet high, and as many wide, and make it as long as the amount of muck on hand will permit. In the course of a month, the muck will be well decomposed and sweetened, and may be shoveled over again and incorporated well together. Then it can be used whenever wanted, at the rate of fifteen cords, as required, to the acre. Supposing the lime to cost from twenty to thirty cents a bushel, this excellent compost can be prepared at the rate of from $8 to $10 to the acre.

For fields lying at a great distance from the barn, a manure of this sort, made on the ground, would be excellent. In the possible lack of muck, turfs from the fence-corners, forest-leaves, rotten logs, etc., might by turned to good account. Of course, if a load or two of some highly concentrated fertilizer, such as hen-dung, privy contents, etc., be carted out and mixed into the heap, it would add to its value. *

Shade a Fertilizer.

One holds that darkness favors the deposition of nitrate of potash, which is a fertilizer, in the soil. Another, that shade brings in the earth-worm, whose perambulations benefit the soil. Wherever there is a flat stone, or board, or heap of rubbish, thither comes the earth-worm. He is a regular sapper and miner, boring the ground for a foot deep, with a multitude of holes, and leaving behind in his exertions a compost which is quite enriching. He is a Jethro Tull, tilling and tilling the ground, and so fertilizing it with the gases of the atmosphere.

Mending our Ways.

The common practice of throwing up dirt, annually, from the sides of the road into the middle of the highway, is a *very* cheap and easy method of mending our roads, but a *very* poor one. For first, this provides no solid foundation for the track, and the covering is of the worst possible material for a road; it is better for the compost-heap than for the highway.

The first want of every road is a hard bottom of some kind. In many localities it may be composed of small cobble-stones, or of broken boulders, or coarse gravel, or the slag of furnaces—anything that will stand firm under heavy pressure, and which will afford drainage in wet weather. An excellent practice—perhaps the best—is to take off about six inches of earth from the middle of the track over a space at least twelve feet wide; lay a good frost proof drain along the middle; then cart in loose stones from the field, or the refuse of the quarries, enough to fill up this trench, putting the large, flattish ones at the bottom; break the others into fragments of convenient size with long-handled stone-hammers, and pound them down compactly together. Now draw on gravel, from two to three inches in depth, rounding the whole off smoothly. It is of the highest importance that the middle of the track should be several inches higher than the sides, so as readily to turn off the water which falls upon it. Finish the work by making shallow, saucer-

shaped ditches on each side of the road-way, to carry off the surface-water. Such a road will be durable, yet will need occasional repairs, which should not be neglected until the foundation is broken up. All that is needed, is an annual light dressing of gravel to fill up the ruts, and to keep the surface well rounded and smooth.

Where gravel does not abound, resort may be had to shale or slate-rock from the hill side, or the refuse of furnaces. But whatever material is used, let it never be forgotten that the one indispensable thing is, first to make a hard, firm bottom, and then to keep the surface well rounded and smooth, so as to shed water quickly into the gutters at the sides.

Roads on the hill-side are harder to manage than those on level ground. Here, too, the hard foundation is needful, and the rounded top. But in addition, there should be turn-outs, or water-breaks, every five or six rods, to turn off the water from the track; otherwise the road will soon be worn into deep gullies and spoiled. These, however, should not be so large as they are sometimes made—a foot in hight is enough, and they should be laid at such an angle that the water will quickly run into the side gutters.

The Great Bee-Master.

Translated from the German for the Amer. Agriculturist.

Crossing the River Oder from West to East, near the City of Brieg in Upper-Silesia, we are at once in the land of the "Wasser-Polaken," a Polish tribe under the dominion of Prussia. We must, however, wander about ten miles over a sandy plain and through gloomy pine groves, ere we reach the Polish village Carlsmarkt (Karlovizze). This little village with its small Catholic parsonage has been for about ten years the attraction of travelers from all parts of Europe, nay even from America, for here those improvements in bee-keeping began, which have raised this branch of agriculture to a hight, which it had never reached before.

The garden of the parsonage is well-stocked with hundreds of bee-hives of various forms, many of them of original designs, and the air is filled with thousands of humming bees. Among them, in a plain dressing gown, a little velvet cap on his head, walks a simple, active man, as quietly as if they were some of the blossoms that the morning breeze blows from the trees. The bees sit on his neck, back, breast and hands, even in the wide sleeves of his gown, yet this does not disturb him in the least. Here and there he takes them off gently and lets them fly, smiling quietly when some visitor takes fright from the bees, or shrieks when a bee stings him. He, himself, is seldom stung, and if it ever happens, he cares as little as if it were the bite of a musquito. His look is steadily fixed on the hives and its inmates who swarm around him. If his visitors ask him questions, his answers are rather short; one must know how to ask him interesting questions, to induce him to enter into a conversation. He who wishes to learn something about the management of the bees, must learn to see and observe for himself. This is the habit of the Bee-Master, whose countenance is so good-natured and simple, and yet not wanting in spirit, and who shows a certain reserve, or rather bashfulness, except when he forgets himself in his enthusiasm for his subject.

This man is Dzierzon, the pastor of the village. He is of Polish extraction, as his name shows, and knows the bees as if he were one of them, and has learned how to educate them. They must do what he will; if he want honey, they must make honey; if he want wax, they must make wax; if he want more bees, they must breed. This power he has attained by thoroughly learning the nature of the bee. According to their nature, he takes advantage of their instinct and faculties, avoiding everything which they dislike, protects them from their enemies, nurses them in their diseases, and renders, so to speak, their lives comfortable. And the consequence of all this is, they are able and willing to work for him in the way he chooses, to the utmost of their power, like the people of a kind-hearted manufacturer who cares for them like a father. One must have seen Dzierzon's continual care and watchfulness over his little pets to gain an idea of the "*Bee-Father comme il faut.*" He forgets nothing that must be done or changed at the hives, to protect them from rain or the burning sun, etc., and every bee which he sees exhausted, is taken up by him and carried to his home. On cold mornings he goes about with a little box, gathering the benumbed bees from the ground, and warms them by keeping the box on his body. His activity is thus not small, since he possesses other apiaries besides that at Carlsmarkt, and cares for all of them with equal tenderness. And he takes in hand also hammer and saw, auger and pincers, and repairs his hives as well as any artisan.

More than any other, Dzierzon possesses two qualities: judgment and power of observation. By them he has penetrated into the very mysterious life of the bee, deeper than any mortal before him. Nay, so minute have been his investigations, that scarcely any essential characteristics have remained undetected. He astonished the natural philosophers at his first appearance before the public with his discoveries, showing that the queen-bee is impregnated but once in her life, and that she is the only egg-laying bee in the hive. The more these two discoveries were doubted at first, the greater was Dzierzon's glory, when he proved the incontestible truth of the same, by that tribe of bees from Upper-Italy, which is of a yellowish color, and which Virgil made famous by song. Dzierzon introduced these bees into Germany in 1853 and the *yellow* queens from Italy produced, crossed with the *black* German drones, again and again *yellow* bees, while the *yellow* queen-bee born in Germany, according to the black drones with whom they lived, produced *black* or *blackish* bees.

Further trials founded upon this difference of color, gave full proof of the truth of Dzierzon's statement, so that it is no longer doubted, and Dzierzon stands before us as the greatest theoretical and practical bee-cultivator in the world. Before Dzierzon, the whole economy of bee-keeping, a few cases excepted, consisted in depriving the bees of as much honey as possible, which was naively styled "robbing." No one had formed an exact idea of their nature and disposition. Superstition thought it only necessary to tell the bees, when their master was dead, lest they should die themselves. The little creatures were left in those places in which they had been found in their wild state, i. e. hollow trees.

All this Dzierzon has thoroughly improved. He teaches the breeding and rearing of bees according to a regular plan. According to his method, one may be independent of the whims of the bees, can make use of their services at the right time and in the right way, can breed bees enough in a few years to fill hundreds of hives, and again arbitrarily lessen their multiplying and gain the more wax and honey, at pleasure.

"Mr. Smith, I wish to speak to you privately; Permit me to take you apart for a few moments." Smith—(who was not in the least frightened)—"certainly, my dear sir, if you'll promise to put me together again all right."

A Farmer's Experience in Kansas.

To the Editor of the American Agriculturist.

I emigrated here in the Spring of 1858, and was just in time to put in a good crop of late corn. The many different instructions in regard to breaking up prairie, induced me to experiment until I found the best method. The first year I broke about three inches deep, and in the fall I perceived that it did not '*rot*' as I had expected. Accordingly, the next year, '59, I broke two inches deep, and my greatest expectation was fully realized. I found the sod completely loose and very easily cross-plowed for fall wheat. I find that breaking the sod and letting it crumble is the best plan; the fall rains have a much better chance of washing it down than if it lay flat upon the 'under sod.'

My experience has led me to believe that corn must be planted (in this State) either very early or very late. I have tried it both ways, but have always found the late corn to do the best. The wheat crops are different. Spring wheat should be sowed as early as possible, and fall wheat the same. Some have differed with me, but at last have found that early wheat always does the best.

As to potatoes, I believe that in this section of country at the present time, they will amount to nothing. The vines are very thrifty and a dark green, and do very well until about the time they begin to blossom; then a very small bug, resembling the "lightning bug," swarms by the million, lighting upon the vines, completely stripping them of their leaves and stems. If some preventive could be found to kill them it would make thousands of dollars for the man that invented it. Any thing that grows upon vines (potatoes excepted) will do very well here. Watermelons grow to an enormous size. I raised one here in '59 that weighed 56 lbs.; ten men eat what they wanted of it and there was enough left for me. I sold the melon for $2.50. This year, however, they seem to be scarce; no person here planted them. I am fully satisfied that this is the best stock-raising country in the world. Cattle will live the year round independent of man's labor.

WILLIAM H. LAMB.

Look out for Weeds!

What, *now*, when the growing season is so nearly over? Yes, now, emphatically NOW. Just at this season, especially in the potato fields and gardens, and by the sides of fences everywhere, weeds are ripening their seeds and scattering them far and wide over the surrounding land. In former days, when the potato held its leaves fresh and green throughout the entire Summer, weeds were smothered out, and the ground nicely cleaned for the next crop. But of late years, since the blight has set in, the tops die early, and weeds spring up and get vigorous possession of the land. Special care is needful, therefore, to subdue these interlopers. Go through the fields, at once, and cut down or pull up the luxuriant weeds before they ripen their seeds and scatter them in myriads over the field. By all means pull up those in the garden. Pile them all in heaps, and as soon as partially dry, mix them in a brush heap and burn them, or better, add them to the manure heap, where fermentation destroys the vitality of the seeds.

Now for a General Clearing Up.

Commence about the buildings. There may be the neglected stables which have been used while vacant in Summer, as receptacles for loose straw, empty barrels, broken implements, and all sorts of rubbish stored there amid the haste of the season's work, to get them off from the barn floor, and "out of the way for the present." The room will soon be needed to shelter stock during cold nights and inclement storms.

The poultry house may need cleansing. If the deposits have not been removed, add them to the compost heap. Thoroughly cleanse the roosts and give the whole apartment a good whitewashing as the best preventive of vermin.

The barn-yard should never become the dismal swamp too often witnessed toward Spring. Arrange drains to quickly carry off falling rain, provide eaves tronghs and leaders to conduct the water from the buildings away from the yard. If water for stock can not be conveniently brought to the yard from other sources, a cistern to receive that from the roofs will give a large supply of the best quality. Raised walks will greatly add to comfort in the daily visits to the different departments during the Winter.

Many meadows are disfigured and the grounds worse than wasted by scattering thickets, bushes and stumps. These, and hedge-rows along the fences and in the corners, are the magazines of weeds which send ont their marauding forces yearly. Take them ont by the roots; aeres may be added to many farms in this way. The roadsides should be cleared of such nuisances.

A large stock of firewood may be gathered on many farms by collecting broken rails and half decayed fencing materials which lie scattered about the premises. There are also fallen trees and branches broken off by storms in the woods which may be turned to good account in the woodpile, if gathered before covered with snow.

In short, let there be a general clearing up of the premises, so that winter may find every thing prepared for its coming, and the farmer may have the comfortable feeling that all is *snug*.

Hardy Trees and Plants.

No one can take up a nursery man's catalogue, without seeing certain trees described as "hardy," "half-hardy," "slightly tender," etc. The same thing is seen in horticultural books and papers. Now this is all well: it helps one to arrive at an approximate idea of the character of the tree, but it does nothing more. For experience shows that hardiness is quite a relative term, depending on soil, exposure, elevation, and other things. The only way to ascertain with certainty whether a tree is tender, or no, is to *try it*. Give it the average treatment of other things; don't nurse and pet it, neither handle it roughly. For the first Winter, a little protection may be allowed, but not afterward. If it succeeds well for two or three years it is probably hardy.

Cheap Paint for Rough Fences, Out-Houses, etc.

The Scientific American says: "Pulverized charcoal and litharge (oxide of lead,) in equal quantities, mixed with raw linseed oil, makes a cheap and very durable dark-brown paint for rough boards of out-houses. It is also a good paint for exposed iron work. The addition of yellow ochre makes it a dark-green color."

This appears to be a good recipe, if charcoal can be conveniently pulverized finely. It would need to be passed through a fine sieve to remove the lumps of coal. Probably the coal dust with the litharge would form a good body, while the litharge would make it dry rapidly. For producing black color merely, it would be cheaper to buy lampblack, which is in reality a very finely divided charcoal collected from the smoke of resin or turpentine. In ordinary times lampblack is very cheap and might be used instead of the charcoal. The greenish tint given by the yellow ochre would be preferable to the dark or blackish brown of only the litharge and coal or lampblack. Can any one speak from experience in regard to the above recommended paint?

How to Make Handy Farmers.

We use this heading to denote those men who are skillful, and ready in doing whatever is needful to be done on the farm. A thorough agriculturist ought to be an intelligent man in more departments than one. He should know a little of Chemistry, in order to understand the theory of manures, the nature of different soils, the action of the atmosphere, etc., etc. And Botany would teach him the names, the origin, and the most scientific mode of managing the grasses, grains, vegetables and weeds within his domain. Geology would teach him very much about the subsoil. The elements of Architecture would help him in building a house or a hog-pen. Philosophy would not come amiss. Not that he should be a learned professor in any of these studies, but a slight knowledge of them, and the possession of books treating on these subjects would be very useful to him. With a little effort, he could then easily "post" himself on any subject requiring his immediate attention.

But this is not the precise point we are aiming at. It was a more practical matter, and was intended to urge young farmers to become skillful, handy, in all the operations of agriculture. An illustration or two will show what we mean. John Smith is a hard-working farmer. From January to December, and from morning to night, he is ever busy; but he does not always work to advantage. He always works in a particular way, having no skill in adopting new and improved methods to save labor. He is not handy at all sorts of work. He can hold a plow, but can not mend a harness; he can hoe and dig like the veriest slave, but can not repair a broken tool: whenever such an accident happens, he has to stop his most pressing work, and go a mile or two to the village to get mending done which he ought to have been able to do himself. He can drive a horse, or yoke of oxen, but can not doctor them for a bruise, or other slight ailment. Yes, a good farmer is he, yet with certain important drawbacks which add much to the drudgery and cost of his labor.

John Jones is made on a different pattern. He is as industrious as John Smith, but don't work as hard. He turns everything to account, and *makes* circumstances favor him. If one method will not serve his purpose, perhaps another will, and he tries it. He has a knack at doing a little of anything and everything. If any of his roofs leak, he can mend them; yes, and with the help of a few hands, can shingle them complete. His awl, waxed ends, and a few pieces of leather in his tool-shed, enable him to mend his harness quickly. He can repair a bob-sled and paint it. He can graft, and bud, and prune his fruit-trees, and do it well; in short, he is a Jack-at-all-trades, and, in a good degree, independent, and master of his situation. Such a man is bound to succeed, be his avocation whatsoever it may.

The way to multiply such men is to commence early. Let the father and mother teach their children to help themselves. Give them a few tools to work with at their leisure. Encourage them to make and mend, and to become "handy." Praise their successful experiments. Inspire them with the just pride of being independent, of being able to take care of themselves, of accommodating themselves to their circumstances, and of making events bend to their will. The seed thus early sown will spring up and bear fruit abundantly in after years.

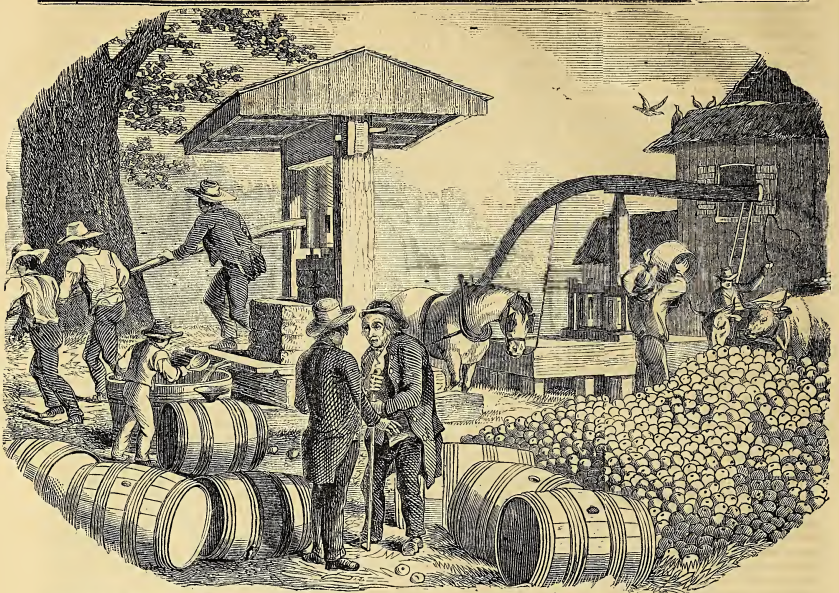
Sweet Potatoes Successful at the North.

Upon our table is a sweet potato worth looking at. It is well proportioned, 12 inches long, and girths over 13 inches; weight 3¾ lbs.! It was grown by Wm. F. Walker, commission merchant of this city, at his country place on the Passaic River, six miles north of Newark, New-Jersey.—We notice this potato more particularly, to call attention to the fact that Mr. Walker's experience confirms what we have all along claimed in the columns of the *American Agriculturist*, viz: that sweet potatoes can be advantageously grown in this latitude, and further north. Mr. Walker cultivates from one fourth to a full acre every year, for his own family use. He says he can, on his soil, which is sandy, produce a hundred bushels of sweet potatoes, cheaper, and with more certainty, than the same amount of mercers. He prepares the land the same as for other potatoes, taking that which was manured broadcast the previous year, and, after plowing it, opens furrows with a plow, shakes in a light coat of well rotted barn-yard manure, and throws back the soil with a plow, one furrow from each side, leaving ridges 2½ to 3 feet apart. The plants are set along these ridges, 1½ feet apart. A plow is run along between the rows, followed by the hoe, before the vines get too large. After this, say twice during the season, the vines are gathered up and twisted in masses, and laid along the top of the ridges. This prevents their rooting at the joints, and also lets the sun in upon the soil. The potatoes grow large, and are of excellent flavor. The variety is what is called the Nansemond; the seed or vines originally came from Mr. Murray, the well known sweet potato grower of Ohio.

In addition to the above, we will say, that we are daily using a full supply of excellent sweet potatoes grown on our own place, where they are quite as productive as the common potato, and grown quite as readily, with little if any more outlay for seed. For our method, see p. 108.

How to Keep Sweet Potatoes for Winter and Spring Use.

Contributed to the *American Agriculturist* by J. C. Thompson, Staten Island, N. Y. Select the first clear drying day after the frost blackens the vines. With a grass hook or scythe cut off the vines and roll them out of the way. Use a fork to lift out the tubers; lay them on the top of the ridge to dry. Dig until noon, then begin to pack, taking those first dug. Have dry barrels or boxes with plenty of dry cut straw or fine dry straw ready; take straw and barrels to the field, put in first a layer of straw and then a layer of the sizable potatoes. They must be handled as carefully and packed as nicely as eggs. When full, cover with straw, and move carefully to a dry, warm room or cellar—if to a cellar, keep them up from the floor, and away from the wall; don't move or disturb them in any way; moving brings on decay. Keeping dry and warm is the great secret of success.



Cider—Stimulants—Cider Vinegar.

Cider making in the olden time was reckoned one of the important parts of farm labor. A goodly row of cider barrels must be ranged beside those of beef and pork, and the majority of farmers would almost as readily have dispensed with one as the other. The cider pitcher stood regularly upon the table at meal times, and the jug was a constant field companion. Happily that day is past. Experience has proved that more and better work can be done on the farm without than with alcoholic stimulants. (Fermented cider always contains a large amount of pure alcohol.) Every exaltation of the feelings is followed by a corresponding depression, so that in the end there is no gain of strength from stimulants, while the system is more rapidly worn out by these changes from the normal state. In surgical operations, or in cases of extreme sudden depression, it is sometimes necessary to borrow a little from the future, by resorting to temporary stimulants; but as a rule no permanent good can come from them to a person even in but moderate health. Good nourishing food—like beef steak cooked rare—well masticated, adds positive strength, and is the best of all stimulants. But supposing cider to be uninjurious for the time being, there is always great danger that the use of this, or of any of the beers, which are flat and stale unless they contain more or less alcohol, will develop a taste and craving for stronger alcoholic drinks. The general belief of the above facts has so reduced the amount of cider manufactured, that for years past not enough has been made to furnish a supply of vinegar. It is difficult to obtain a good quality of the pure article in most of our cities. The market is filled with unwholesome compounds, made from the refuse of distilleries, and with acids of various kinds. None of these deserve the name of vinegar, while in some cases they are absolutely poisonous, or at least ruinous to the teeth. Those who have continued to make cider for vinegar, find a ready sale at good prices, and probably apples may in this way be turned to better account than by feeding them to stock, although they are by no means unprofitable when fed.

The requisites for making good cider vinegar are few. Sound apples free from dirt, ground fine will yield the staple. It is well to arrange for two sorts, "extra" and good; the former to be made from the first pressings of the pomace, by which is obtained all the juice possible to be extracted without watering. After this pomace is removed from the press, pour a few pailfuls of water upon it, and shovel it over occasionally for a few days; then press it again, and add two or three quarts of inferior molasses to a barrel of the juice. Keep in a warm situation, and it will ferment into fair vinegar—far better than much of the trash sold under that name.

Vinegar is usually produced by simply allowing cider to stand in barrels with the bung hole open, until the second or acetous fermentation is completed, and it requires several months for the process to be finished, the time varying considerably with the degree of temperature. As fermentation depends upon the absorption of oxygen from the air, it will be much hastened by exposing as large a surface as possible. In some establishments where the manufacture is largely carried on, this is accomplished by allowing the liquid to drip slowly through beech wood shavings; the work of oxydation is finished within a few days instead of extending over months. The old-fashioned plan, however, will answer all purposes of ordinary vinegar making.

What Apple Trees to Plant.

A correspondent of the *American Agriculturist* makes the following well-timed suggestions. Select none but well tried varieties, such as are recommended for general cultivation by the American Pomological Society; leave new and untried varieties for amateurs and nurserymen until they are thoroughly tested. Do not be misled by agents or tree peddlers, few of whom are competent or reliable as advisers.

Purchase none but first class trees, perfect in root and branch; inferior or defective trees are dear at any price. Plant liberally of choice varieties for family use the year round, and if animals be kept, procure plenty of Summer and Fall varieties of sweet apples for their use.

For market, choose but few sorts. Winter apples pay best for the general crop. The Baldwin is the best paying market apple, and next in order of preference is named the Northern Spy*, Roxbury Russet (inferior in quality, but a

* This variety succeeds well in some localities, but can not be recommended for general planting. Except in favored regions it is a shy bearer. (See page 147, May.)

long keeper, and bears handling and transportation well) Wagener, Swaar, and Rhode Island Greening. No variety bears more uniform and abundant crops than the Greening, and it usually commands a fair price; but it bruises easily, and does not keep well long enough to be sent to a distant market in Spring. When the crop is large, the Fall price is not usually remunerative. In many localities the Baldwin yields as well, bears handling better, keeps longer, and in winter commands fifty cents per barrel more. The beautiful Lady Apple, when well cultivated, bears good crops, and commands the highest price in New-York, London or Paris. It bears transportation well, and is worthy of more extensive cultivation. Where suitable land is cheap, an extensive orchard of this variety would prove a very profitable investment.

For family use I would name the following in their order of ripening: Early Harvest, Sweet Bough, Golden Sweet, Summer Queen, Primate, Porter, Maiden's Blush, Jersey Sweet, Gravenstein, Fall Pippin, Fameuse, Twenty Ounce, Esopus Spitzenburgh, Tallman Sweet, and the Winter varieties above named, except Roxbury Russet, and this list will answer every purpose for those residing near large cities where they can get fruit to market in baskets conveniently at any time of year.

For the American Agriculturist.

Root-Grafting Apple Trees.

Apple stocks of the size of a lead pencil are selected, and their roots cut in lengths of four inches. The upper part of the cut is sloped one inch, and slit with a thin knife—a common shoemaker's knife with a narrow blade is generally used. The upper cut of a root is the best. A cion of the particular variety wanted and of about the same size as the root, is cut in same lengths and sloped and slit in the same way, at the bottom to correspond to the cut in the root; then they are slipped together so as to match exactly on one side, and bound with a narrow strip of waxed paper. The cion should be cut square across at the top of a bud. The grafts, as they are now called, are placed close together in shallow boxes, mixed with damp saw-dust and stored in a cool, dry cellar until the frost is passed. They are then planted, with a round or flat dibble, in rows, by running down the dibble a few inches, inserting the graft, running the dibble down again on the side of the graft, and just below it to fasten the bottom well, and then pressing the upper part of the dibble against the side of the graft. Be particular to fasten the bottom well to exclude the atmosphere and press the whole firmly to prevent drying. Two buds should be above the surface; the grafts should be eight inches apart in the row and the rows three and-a-half feet apart. The upper four inches of the roots with their stems are often planted at the same distance apart and budded in July of the same year—these make rather better trees to sell. Nurserymen usually root-graft because it is done in the Winter when help is plenty; one thousand grafts are usually made in a day. Waxed paper is made by mixing six pounds of rosin and one pound of bees wax with one pint of linseed oil or lard, and spread with a brush on manilla paper—newspaper is generally used but it is not as good. When used it is cut in strips one half inch in width.

Toledo, Ohio. J. H. C.

Apple Pomace for Fruit Trees.—A writer in a French Pomological journal states that he has experimented largely in using apple pomace as manure for apple and pear trees, and with the best results. The soil was removed from about each tree to the depth of the upper roots, and three or four forkfuls of the pomace thrown in and covered with earth. A remarkable impulse was given to the growth of the trees, and in several instances where pears had cracked badly, good sound fruit was produced.

Tim Bunker in his Garden.

"What kind of pears do you call them, naber?" asked Jake Frink as he stood admiring a dwarf Flemish Beauty, loaded with ruddy, russet fruit.

"That is a dwarf pear tree," said I.

"It looks like a giant," said Jake, confounding the tree with the fruit. "I never see such pears in all my life. Nothing but perries 'll grow on my place. I've heern of them dwarfs, but never tried 'em. Do all come as big as that?"

"Well, you see, they graft almost any kind of pear on quince, and that makes the tree grow small. But the fruit is generally bigger than it is on the pear stock. Dwarfing does not alter the fruit. It only makes the tree small."

"Dew tell. You see I thought dwarfs was all of one kind. I shall have to own up on these pears, naber. I tell'd you at the time you were settin 'em eout, five years ago, that they never would come to nothin'. Uncle Jotham sot eout a lot, and his'n didn't dew nothin'. They grew miserable scrubs, got lousy, and worm-eaten, and I guess there want one left arter three years. But now I see Jotham Sparrowgrass and Timothy Bunker are tew individuals, if not more."

Jake Frink's eyes hung out as he went round the garden, spying the pears, about as much as when he saw that first crop of hay in the horse-pond lot. I have kept back my pears from bearing more than most cultivators do, and think I find my account in it. Gentlemen who own small lots in the city or country village are apt to be in a hurry to realize; they let every fruit that sets hang on even the first year. This is particularly bad for the bottom limbs of dwarfs, which are the most difficult to coax into a generous growth. If they bear much fruit they will not make wood, and the bottom of your pyramid is spoiled. I have seen a good many dwarfs killed outright by overbearing. With the standards there is not so much danger—indeed, none at all, if we except the Bartlett, and a few other early-bearing varieties.

I picked off all the fruit for three years, and threw all the force of the trees into wood. If I can get good stout wood well ripened in the Fall, I consider this the best crop a tree can bear for four years at least. If a tree is a bad grower, I keep it back still longer. I have some standards out nine years, and dwarfs six, that have never borne a fruit, and I guess I know what I am about. They have blossomed profusely, and some of them set fruit—but I have pulled them off, though it went very much against the grain.

When they come into bearing, after such delay, there is great satisfaction in looking at the fruit, some in eating it, and more still in giving it away. You see, in growing a handsome fruit, perfect after its kind, a man enters into co-partnership with nature. He helps nature to do something which would be impossible without him, and nature helps him. The joint product is as much an honor to man as it is to nature. A basket of fine pears glorifies a gardener as much as a great speech does an orator. The giving away of the fruit or putting it upon exhibition, is the publication of his speech. It sets the gardener to talking in a very mute kind of way that all sensible people comprehend. I should call an orator rather stupid who spouted his speech to the winds. He wants an audience. That gardener lacks both wit and manhood, who is content with eating his own pears. They should have a chance to speak for him.

And this reminds me of a circumstance that has just happened in Hookertown. You see a week ago Sunday, Mr. Spooner preached a sermon on the text "By their fruits ye shall know them," applying the doctrine among other things to Slavery, and showing up this wicked war as one of its fruits. He pictured out a big tree, and the branches hung with treason, rebellion, oppression, theft, murder, and about all the vices that disgrace mankind. Now, you see, human nature is weak, and my mind instead of following the thread of discourse, was running on the fruits in my garden. My Bartletts were just in their glory, and a man couldn't have said fruits on any occasion, without my thinking of them. So when we got home from meeting, I said to Mrs. Bunker: "Sally we needn't be ashamed to be known by our fruits, suppose we send Mr. Spooner a basket of Bartletts."

"Very well," she said. "Send the basket heaping full and send it the first thing in the morning so that he will know what it means."

Sally, you see, is one of Mr. Spooner's right hand men, or rather women, a modern Dorcas, to whom it seems to come natural to help the poor, and make other folks happy. So I thought it fair to credit her while I credited the minister, and put on top of the basket a card: "With the compliments of Mrs. Bunker, Matt. 7: 20."

I am getting to be pretty well along in life, and my enjoyment of gardening increases with my years. I am only sorry that I had not begun to plant fruit trees earlier. I hope your young readers will learn wisdom and improve the present season.

Hookertown, Sept. 15th, 1862.

Yours to command,
Timothy Bunker, Esq.

Preparing for Winter.

In this month, most preparations for Winter should be completed. It will not do to wait until the ground is frozen and covered with snow. Work done at such a time will be poorly done. Indeed, much of our fall work should be already accomplished; but let there be no longer delay.

In the Garden—Have an eye to those late vegetables. The cabbages—are they all gathered into the cellar, or covered nicely in the garden, where they can be reached without difficulty? See that they do not get water-logged. Are they likely to be infested by mice? We have known whole stacks to be thoroughly riddled by them. See that they have good ventilation, both those in the cellar and out of doors. And as with the cabbages, so with turnips, carrots, beets, celery, etc. Guard all the latter from frost, mold, rot, and excessive dryness. Keep them sound and plump, ready for man or beast.

Is the garden well ridged up, so as to throw off the surface water, and to bring the stiff, bottom clay up to the frost? Whoever wants to deepen his soil, to kill noxious grubs, and to have his garden dry and early in the Spring, will be sure to throw it up into ridges in the Autumn. A long spade, and a strong arm and will, can accomplish this quickly. Lay the ridges in a different direction every Fall.

The bean-poles, stakes for tomatoes, melon and cucumber boxes, and any other frames for small hot-beds—are they all under cover? It is well known that they will last many years

longer, if this care is given them; and besides, a garden looks slovenly, with its summer furniture lying around loose. One's reputation for order and neatness is worth something.

Has that wet corner been drained? It has troubled you for several years. Vegetables, vines, and fruit trees planted there have struggled hard to live: you have often wished it drained, but have not yet found just the right time for doing it. *Now*, the present week, is just that time, for the ground is clear of crops, and you have the most leisure. Cut the drain at least three feet deep; secure a good fall and outlet; if possible lay hard-burned pipe, of not less than two inches bore, making good joints, and covering all well before hard frosts. That piece of work will yield you real satisfaction.

A word or two for the grape-vines. The first week of this month is perhaps the best season for pruning. Later in the Fall or Winter, it is too cold for comfort to the fingers, and the work is not apt to be done carefully. If the vines are to be laid down and covered for the Winter, (and there are few if any kinds not thus benefited,) it is best to prune before putting down. They take up less room, and you have the cuttings for propagation if desired. The mode of pruning will depend on the method to which the vines have previously been subjected. If it be the *spur-method*, then cut back the side-branches to two good buds. If it be the *renewal*, cut out the old bearing wood down to a strong bud at the base, and cut off the new cane (the present summer's growth,) at the top of the trellis. Now, bend down the canes carefully to the ground, fastening them down with cross stakes. Throw a little rubbish over the canes, and upon this put a few inches of common earth, only just enough to hide the vines from sight. Too thick a covering is as bad as none.

Are the roses, vines, shrubs, and other plants of the flower garden protected against injury in Winter? Even the common June roses bloom better if laid down and slightly covered. The hybrid perpetuals are not safe without some protection. The Bourbons, Noisettes and Chinas absolutely require it; indeed, experience shows us that the best place for them between November and May, is the cellar, or green-house, or cold frame. Around the crowns of nearly all herbaceous plants and rare shrubs, a few leaves or a handful of rubbish should be gathered and a shovel full or two of manure added. The good effects will be visible next season. Newly-planted shrubs and small trees, (conifers in particular, if not certainly hardy,) should be blanketed with evergreen boughs, tied loosely about them. If any one is experimenting with rhododendrons, kalmias, azaleas, etc., we would advise him, for at least the first year, to stick in a few pine or cedar branches among them. Or, better still, drive in a few stakes, and tie to the evergreens to them; else the snow will beat them down on the tender plants and break them. The broad-leaved plants will be sure to winter safely, and come out in the Spring fresh and strong. We need hardly add that hillocks of earth should be thrown up around the stems of all newly planted fruit trees. This will guard them against the gnawings of field mice, will protect the roots from excessive freezing, and keep the tree ballasted against riotous winds.

ELSEWHERE.—See that the sheds and barns are snug and tight. When the sailor sees a storm coming, he furls the flapping sails, shuts down the hatches, and makes all things trim for the gale. So should the farmer and gardener, on the approach of stormy Winter. Batten up those wide cracks, on the windy sides of wood-shed, stable and cow-house. Give every loose board the benefit of a nail or two. Provide, in every possible way, for the comfort of man and beast. Lay in good supplies of wood or coal. See that the stoves and pipe are in good order. Have the chimneys burned out on some damp, quiet day, not waiting to have it done accidentally, and at a bad time. In short, do now whatever it becomes a good householder to do at this season. Then, when the winds roar, and the snow falls in eddying heaps, you can sleep quietly, knowing that you have done your duty.

Cleaning up the Flower Garden.

While neatness and order are always desirable in this department, there may be too much of even this good thing. In their anxiety to have the flower garden the "pink of neatness" when it can no longer show the pink of beauty, young gardeners are scrupulous to remove all fallen leaves, dead stalks, and whatever might offend the eye. This is very well, provided something be substituted in their place as a protection for the roots that are to bear the severity of the Winter. Doubtless, one reason why many of our fine shrubs and herbaceous plants prove so tender is that they have to go through the Winter *naked*. We strip them of the clothing which nature designed for them, and then wonder that they get frost-bitten!

Look at our wild plants, covered in Winter by their own decaying haulm, by scattered leaves, and the overhanging forest. Transplant them into our spruce parterres, where every brown leaf is swept up in the Autumn, and they would surely suffer, if not wholly perish. So it is with the common domesticated plants of our gardens. Many of them have, indeed, got used to the exposure, yet they suffer from it. The better way is to allow of a little sloveliness in the garden in Autumn, *rather* than expose our favorites to an untimely death. Let the leaves and dry stalks fall down around the crowns and roots of the plants, and so protect them from the vicissitudes of the Winter. This is nature's plan, to be followed *when* we can not improve it.

A very efficient and neat way of affording needed protection is to cover the roots with small branches of evergreens. They lie lightly upon the soil, and are rather ornamental in appearance. If these can not be had, straw, or leaves from the woods, properly secured, will answer every purpose. If neither can be used, leave the dried stalks, and clear up in Spring.

Prepare now for Spring Gardening.

Spring work in the garden is by most farmers left to be done at leisure intervals between the more extensive operations of putting in the field crops. It often occurs that, from press of business, much that should be done in this important department is neglected or slighted, because the leisure is not found, and as a consequence there is but a poor show of vegetables throughout the season, and these always late. Something may be done during this month of November toward early gardening in Spring.

At this time most of the vegetable crops have been secured, and there is sometime to work in the soil. If it be wet, draining now will prepare it for plowing next year before the fields are ready to be worked. If draining be impracticable, plowing and subsoiling will greatly improve it. Trenching, especially on heavy soils and working in plenty of coarse manure or muck, will greatly ameliorate heavy soils. A good coat of manure plowed in now, ready to be lightly cross-plowed and thus thoroughly mixed with the soil in Spring, will give a good rich tilth.

Now is the best time to set asparagus and rhubarb roots, two indispensables in every family garden. If old roots are procured, they will yield at least a partial supply for the table next Spring, and much time will be gained in their growth. Though late, strawberries will live and thrive if transplanted with care immediately. They may yield but little next season, but the work will be done, and when the fruit does come, you will feel abundantly repaid for the labor. Blackberries, raspberries, currants, etc., may all be put in place, also a few dwarf pear trees, if there be space. These trees require much care to produce well, but every cultivator will soon find them his especial pets in the garden.

And the grape vines. Have you a full supply? Do not let the Fall pass without securing enough for plentiful family use. These and the currants, gooseberries and dwarf pears, will be benefited by spreading coarse manure about them as far as the roots extend. The winter rains will carry much of it into the soil, where it will be ready for use by the roots in Spring.

Finally, now is the time to build or repair the fences, gates, trellises, etc. A coat of paint, or even whitewash, would add fifty per cent. in appearance to many a garden enclosure, in addition to its value in preserving the fence.

Blood's Seedling Grapes.

We have received samples of these from Mr. James Blood, of Newburyport, Mass., with an accompanying note, stating that they were raised from seeds of Malaga raisins. Mr. B. is doubtless sincere in his belief that such is the fact, but from the peculiar muskiness both in taste and smell, the thick leathery skin and hard pulp, so little removed from the ordinary wild grape, we should have judged them seedlings of the fox grape. Two kinds were sent, one purple, the other amber color; the former the best, but neither would seem to be very desirable where the Concord, or Hartford Prolific will mature. Mr. Blood says they are hardy, and ripen from 8th to 12th of September. *

A Tour in My Garden.

MR. EDITOR:—While some men travel over land and sea in pursuit of pleasure, I contentedly stay at home, and take a daily trip through my garden, my wife and children accompanying me. Would you like to overhear our quiet talks? Now, we touch upon

DWARF PEARS.—Wife and daughter ask if these trees are called dwarf because they look rather feeble, and bear so little fruit. No, no, dears: in your simplicity, you are hard upon me. The trees are made dwarfish by being budded on quince roots, but they ought not to look feeble, and the fruit ought to be large and abundant. I ought to have manured the roots last fall; then the trees would not reproach me so. But next, look at our

MELONS.—How did you manage *them*? I started them on pieces of turf in oyster-kegs, (sawed in two,) plunging them into the soil of a hot-bed. When they were large enough to transplant, the season was ready for them; and all I had to do was to turn them out bodily from the kegs, and set them out, turf and all. This gave them less check than though I had sown

them in the hot-bed itself and transplanted each plant separately. I think ten days were gained in this way, and I mean to follow it every year.

GRAPE VINES.—And did you raise these little ones from seed, father, just as you did the melons? No, indeed. Over yonder, are several rows of vines raised from seed of the choicest varieties. They will bear fruit next year; yet I think, judging from the looks of the leaves, that the fruit of most will be poor. For, you must know, that the seeds of grapes do not produce vines exactly like their parents. These plants, on this side of the walk, were raised from cuttings put into the ground this Spring; I dug trenches a foot deep, spread a little sand at the bottom, set in my cuttings in a slanting direction, and covered them, leaving only one bud out of the ground. These plants are just like the parent vine from which the cions were cut.

THOSE QUINCES are large and beautiful; have you any secret process for beating your neighbors? No; I simply set out healthy plants in good soil; I keep the ground clean and well enriched. A little salt is spread on the border once in two years, but I am not sure that it is of much importance. I thin out the old wood every year or two, and that is the whole secret.

And so ended our little stroll for one day. Don't you think, Mr. Editor, that we can ourselves get some good suggestions from our families, while we also teach them valuable lessons in gardening? So thinks A READER.

The Adirondac Grape—Interesting Report.

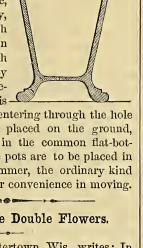
This new grape has heretofore been shown at a few Northern Agricultural Exhibitions, and lately at the meeting of the Amer. Pomological Society at Boston, and not a few have been incredulous as to the claims put forth in its favor, especially as little has been known of its history or exact locality. Mr. Bailey of Plattsburg, who is as yet the only propagator, sent us a cluster of the fruit Oct. 1st, and we laid it before the Fruit Growers' Weekly Meeting, at the office of the *American Agriculturist*, Oct. 2d. It was pronounced very fine, resembling the Isabella in size, and general appearance, but of a lighter color. It has very little pulp, and a pleasant but not very high flavor. In these respects it so much resembles the foreign grapes, that many gentlemen half suspected it to be an exotic variety, and the fruit grown under protection. To get at the truth of the matter, we proposed that the Society should send a competent uninterested committee to Lake Champlain, to investigate the matter thoroughly, in part at our own expense. The idea was favorably received, a few public spirited gentlemen offering to contribute something toward the expense. The meeting unanimously selected Mr. A. S. Fuller as a suitable person to go on the mission. Mr. F. started on the journey, traveled some 300 miles, and returned in time to report at the meeting on Oct. 9th, as follows:

I went to Plattsburgh, but there learned that the original Adirondac vine was in the grounds of J. G. Witherbee Esq., at Port Henry, in the town of Moriah, Essex Co., about 40 miles north of Whitehall, in latitude 44°. (Mr. W. not being a propagator of fruits, and not attaching much importance to the matter, sometime since agreed to furnish Mr. Bailey of Plattsburg with all the cuttings, except what he gave to his friends). The original vine stands about 10 rods up the slope, and about 50 feet above the waters of lake Champlain. The hills at the base of which the vine grows are some 200 feet high, and shelter it on all sides as well as it could be protected naturally, the valley opening only to the South. The soil is a deep sandy loam, intermingled with the disintegrated rock continually washing down from the hills above. Mr. Witherbee says he first noticed the vine in 1852, and, supposing it to be a wilding, or an Isabella, dug it up, as he supposed; but the next season a sprout from the old root, or a seedling, came up in the same place, and this was allowed to grow. The following winter it killed to the ground, but the next season it made such a fine growth that he protected it at the approach of winter. The following season it produced fruit which ripened some weeks before the Isabella standing in the same garden. This vine has been laid down and covered every winter since, and has never failed to produce a good crop.

The vine at the present time has three shoots from the ground each of which is about 1½ inches in diameter. They cover a trellis some twelve feet high, and sixteen feet long. The vine can not be said to be trained, although a part of the branches have been tied to the trellis. The leaves are now (Oct. 6th,) perfectly healthy, there having been no frost to kill them, neither have they been attacked by mildew. The Isabella and several other varieties in the same garden, are also perfectly healthy, and growing rapidly. The Isabellas are not yet ripe. The vine has every appearance of being an Isabella both in leaf and wood, with perhaps the exception of the *ale* of the leaf overlapping more in the Adirondac than in the Isabella. The points of difference are: The earliness of ripening, and the larger size of the bunches and berries, and the lighter color of the fruit. The clusters are more compact, and the berry is nearly round, while the Isabella is oblong. The quality of the fruit is very good, but not rich; pulp very tender, parting readily from the seed. The clusters of fruit presented herewith, I gathered from the vine myself; it will be seen that they correspond entirely with those shown at our meeting in the office of the *American Agriculturist* last week. I consider it a great acquisition. A. S. FULLER.

An Improved Flower Pot.

The accompanying sketch represents the cross section of an improved flower pot, which has some manifest superiority over those in common use. It has a broad base, and so stands firmly, even when filled with tall plants and when blown upon by high winds. And besides, by the peculiar arrangement of its bottom, it is proof against worms entering through the hole in the bottom, when placed on the ground, which is a great evil in the common flat-bottom pots. Where the pots are to be placed in the soil during the summer, the ordinary kind would be preferable for convenience in moving.



How to Produce Double Flowers.

A subscriber of Watertown, Wis., writes: In a former number of the *Agriculturist*, mention is made of fine specimens of balsams produced from seed several years old. The long keeping of the seed is one secret of success. Balsams are best when the seed is between 4 and 7 years old; stock-gillics, wall-flowers, etc., must be grown from seed at least 2 years old. Treat the annuals named in the very best manner; leave only a few seeds on each plant; sow them in the most fertile and best prepared ground; and yet they will deteriorate from year to year when grown from seed of the preceding year. The reason is obvious. The double flower is a monstrosity, is a disease; the essential organs of the flower, those which in the natural state of the plant should have produced the seed, are wanting, being converted into mere protecting organs, or leaves. But that monstrosity is just what we desire; and the best and surest way to continue it, in perennial and biennial plants, is to propagate by cuttings, layers, or grafting, instead of in the natural way, the parts so severed from the mother plant and brought to form a new plant retaining the desired double flowers.

The Yuccas.

He who wants to adorn his garden with something really *odd*, should have one or two Yuccas. They are unlike almost everything else. The plant they most resemble is the old Century-plant. Mr. Downing suggests that the most appropriate place for them is near the dwelling, on account of their stiff, architectural expression. Set them in ornamental pots or vases, and place them on the corners of a parapet or terrace. The foliage is bold and striking, and the flower-stalks, which shoot up some three or four feet, covered with creamy white blossoms, bell-shaped, and pendulous, are exceedingly interesting.

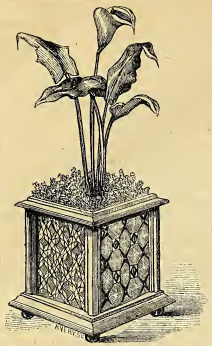
We recollect seeing, a few years ago, one variety of the Yucca growing wild on the shores of the St. Johns, Florida, where it is called by the inhabitants, "Adam's Thread and Needles." This name originates from the sharp points of the leaves, and the thready filaments hanging from either side. The common variety (*filamentosa*) is hardy in the northern States, and will grow in almost any soil. As to exposure, it does best when partially protected by overhanging trees. If set in the open garden, it is well to put a rough box over it in winter, or to throw a few evergreen boughs around it. Yet this is not necessary. A new variety, the *stricta*, is said to be quite hardy and desirable. [The above is from an associate Editor of the *Agriculturist*. We have three Yuccas growing at as many points in an open, exposed lawn, and have given them no protection. They have flowered finely every year since setting out. The roots of hardy Yuccas are now obtained quite cheaply at most of the leading commercial gardens.—O. J.]

The Euonymus.

This shrub is popularly known by several names, as spindle-tree, burning-bush, smoke-tree, strawberry-tree. There are several species—twelve in all, we believe—four of them native to this country, and six of them quite hardy. The English species has four varieties, of which the broad-leaved (*E. latifolius*,) is the finest. These shrubs do not push out their leaves quite as early in Spring as the lilacs, but they hold their foliage later. Their flowers are but little showy, yet the fruit makes up all deficiency. This hangs in clusters of brilliant red, of the size of a strawberry, (hence one of its names) and clings to the stems long after the leaves have fallen, even when covered with snow.

Of the broad-leaved species, Loudon says: "This forms much the handsomest shrub, from its broad shining leaves, and its large, red, pendulous fruits with orange-colored seeds, which, when the capsules open, are suspended from their cells somewhat as magnolias hang from their stobiles." The wood is handsome in winter, being of a dark, reddish green, and with long-pointed buds. It grows from eight to ten feet high in deep soils, and produces greenish white flowers in June and July. To attain perfection, it should be planted in an open lawn, and be allowed to develop itself on every side. It should be in the smallest collection of shrubs.

PRESERVING CARNATION BLOOMS.—To do this, keep the stems well tied to stakes, and soon after the bud expands, tie a soft string around the blossom to keep it from breaking down. Why might not rings of thin India rubber be made to slip over the opening buds, which would expand enough to admit the development of the flowers, and yet would prevent their breaking?



Glass Mosaic Flower Pots.

It is rather a matter of surprise that so few improvements have been made in the style of flower pots for use in the house. The old red earthenware article so commonly seen, is very unsightly, and greatly diminishes the otherwise attractive appearance of the flower stand. Painted wooden boxes are objectionable from their speedy decay, and the broken and disfigured china-ware, pitchers, etc., which are pressed into service, are in worse taste than the red crocks.

There were shown at the recent International Exhibition in London, very beautiful articles for this purpose, made of colored glass set in a light iron frame work, as shown in our engravings. The glass used was of different colors, and arranged in regular mosaic patterns, giving a very beautiful effect. They were of different forms, square, rectangular, octagonal, etc., and of numerous styles of mosaic. The more expensive sorts were very elaborately finished, forming objects every way worthy a place in the most richly furnished drawing room.

We present these as a hint to some of our manufacturers. The only objection will be the cost, but perhaps that may be reduced to come within the means of the masses. Even if the above described styles are not adopted, we look for some improvement over the present rude manufactures, which are entirely out of keeping with the other articles that make up the furniture of the sitting room.

ORIGIN OF THE WORDS NOSEGAY AND BOUQUET.—A writer in the Gardener's Monthly records that Cleland, in his Celtic Vocabulary, says: "gay, applied to nosegay, comes from the Else tongue, in which *geach* signifies a bough or bunch of flowers which might be held to the nose. From the old word *bought*, or little bough, comes the French word *bouquet*, for nosegay.

Beautiful Floral Ornaments.

Hyacinths, as ordinarily grown in glasses and pots, are deservedly favorites. Few flowers give better reward for the little pains required to raise them successfully. A very tasteful arrangement of these with other bulbs is common in Germany, which we do not remember to have seen practised here. Single hyacinths, together with Scillas, Snowdrops, Crocuses, and other small bulbs, are placed in shallow dishes—soup-plates answer a common purpose—and arranged in any form to suit the fancy. The roots spread out and intertwine until the flowers rest on a network that keeps them in their place.

Having selected the bulbs, place a foundation of charcoal, and on this a layer of damp white sand. Set the bulbs a little distance apart, and remove the dish to a dark room where they may remain for about three weeks. This treatment encourages the roots to form plentifully before the buds appear. At the end of that time a little water may be given (being poured down the sides of the dish), and if the roots are pushing the bulbs up out of place, pour dry sand over them, so as to surround them at least half way to their crowns. When the blossom buds and leaves have made a little growth, they should be brought to the full light of a window, and in all respects treated like those in glasses.

Dwarf hyacinths are best for this use. They are raised from well ripened bulbs of the same kind as the large ones, but not much exceeding a large walnut in size. They may be obtained at most seed stores, and will yield a large amount of enjoyment for the money invested.

A very pretty experiment with hyacinths is thus described in the "Parlor Gardener": Having made your choice among the brightest shades of blue, red, and yellow, you must give your greatest care to a charming experiment which will be the source of a very agreeable amusement for you all the Winter. You can procure, at a small expense, two vases of plain, clear, uncolored glass; both of the same form, except that one has no bottom, and is a little smaller than the other. They are to be used as follows: Put into the one open at both ends, one of the finest of your hyacinth roots; suppose you take one of a fine red—a Sultan Soliman, for instance; place this bulb in a position inverse to its natural position, that is, with the bottom up, and the top, from which the leaves and flowers are to come downward even with the orifice at the bottom of the vase. Then you must crumble a mixture of good garden earth and leaf mould over the bulb until the vase is three-quarters full. A second bulb with a flower in strong contrast to the first, say a blue, if the flower of the first is red, and *vice versa*, must be next placed in the vase, so that the top shall be even with the upper orifice. You have nothing more to do than to place the vase thus prepared upon the first vase, after filling it with water. Two similar couples look very well, placed upon two ends of the mantle-piece of a room in which people habitually sit, and where, consequently, fire is constantly made while the cold season lasts. The earth in the upper vase should be moderately watered as soon as the bulbs are placed in it, and then kept constantly moist, avoiding excess, by renewed watering whenever you perceive that the earth is getting dry.

At the end of two days, the crowns of the two bulbs will both send out straight, white roots; those of the reversed bulb turn down in curves, but do not fulfil their functions worse for that. Very soon the two bulbs placed in a contrary position to each other put forth leaves—the one into the air, the other into the water; then you will see appear in the midst of the transparent liquid the buds on the floral stalk, and finally the flowers, as beautiful, as well formed, of as rich a color, surrounded by leaves of as fine a green as the corresponding parts possess, of the other flower planted in the ordinary manner, and vegetating and developing in the air—its natural element. It is true that time is necessary for all this to be accomplished; bulbs planted in October will flower fully in February or March; but is it not a pleasure to watch day by day the phases of development, above all that of the hyacinth which ends by blooming in the water head downward?

Hints on Vases, Statues, etc., for Gardens.

In works of art, like the vases we pictured in a former number of the *Agriculturist* (March, 1861), the vase itself is the principal thing. The base and pedestal are subordinate; they are simply the means of raising it from the ground, and supporting it where it can easily be seen. Hence, they should be of coarser material than the vase; coarser because they are designed to come in contact with the rough earth, because they are to serve as foundations, and because they will thereby set off to better advantage the costliness and delicate beauty and fine workmanship of the vase. And the same difference should appear between the statue, or other figure, and the pedestal on which it stands.

If, then, this principle is a correct one, it would seem that our manufacturers of iron, and terra-cotta vases, etc., err, on the score of propriety and taste, in sending out their wares painted all of one color from top to bottom. To our view, a perfect arrangement requires that the base, rising from three to six inches above ground, should be of granite or limestone, resting on a solid pier reaching below frost. The pedestal, if of iron, should be painted and sanded so as to represent some corresponding material, such, for instance, as red or brown sandstone, indicating, perhaps, a little refinement upon the rough base. Then, the vase itself should be of the purest white, to represent marble. We question the propriety of sanding the vase, at least unless it is quite a plain one, for the sand fills up the finely wrought lines, and defaces and blurs over what ought to stand out in clear relief. It also gives the vase a roughness inconsistent with the idea of polished marble. It is a debatable point whether a vase or other figure should be painted a dead white or with a gloss. The first gives a more marble-like look; the latter protects the iron best.

Many persons no sooner get a vase into their grounds, than they fill it with soil and set out plants in it. Small and very plain vases may be so used as flower-pots, but large and finely wrought specimens should be regarded rather as pieces of sculpture, and be kept inviolate and

in the most scrupulous neatness. They are copies of great works of art, beautiful in form and symbolic device, interesting from classical associations, and so, worthy to be carefully preserved and contemplated for their own sake—not for the perishable flowers they happen to contain.

THE HOUSEHOLD.

Good Butter in Winter.

For the benefit of my lady friends, I will give my experience of twenty-five years, in making nearly as good butter in Winter as in Summer. In the first place, we suppose the cows to have been fed on good feed. After the milk has been strained, put it on the stove to heat, either in the pans or in any other way thought proper. Do not make it too hot, or the cream will not rise; it may then be placed in a clean cellar, free from vegetables or any thing that will give the cream an unnatural taste, or in a cupboard with a canvas door, in a moderately warm room; if in the latter place, it should not be put in until the steam has passed off, otherwise the shelves will be liable to mould. The milk should not stand longer in Winter than in Summer, or the butter will be bitter. In 36 or 48 hours it should be skimmed, if in a cool place, sooner if in a warm one. If the milk is thought to be too rich to give to the pigs, let it stand longer, and use the cream that rises on it for shortening or in some other way than for butter.

If the milk has been kept in a cool place, take the cream to a warm room a day or two before churning. If you wish the butter to look and taste like grass butter, grate orange carrots, put some hot water or milk to the pulp, strain and add it to the cream, which should be a little above 60° when you commence churning. A common sized teacupful will color six pounds of butter. After churning, draw off the buttermilk, put cold water in the churn, and churn a few minutes, and if managed right, you will never fail of having good butter. I rejoice that the prejudice against washing butter with cold water is slowly passing away. Heating the milk I believe is an English method, and ought to be more generally practised, then there would not be so much poor butter in the market. So says a BUCKS CO. FARMER'S WIFE.

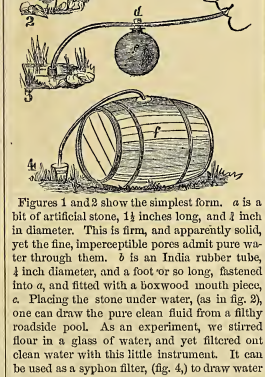
Eaglewood, Pa.

Mica Lining for Butter Boxes.

A novelty that promises to be useful, has been exhibited at the *Agriculturist* Office, in the form of wooden butter boxes lined with *mica*. (This is the material used for transparent stove doors, lanterns, etc.; it is popularly but wrongly called isinglass, from its resemblance to that substance. Isinglass is a translucent glue or gelatinous substance, prepared from the intestines of fishes, and used in cookery for jellies, charlotte ruse, and similar purposes.) Mica is found abundantly in some quarries. Thin sheets of it, closely joined, are placed on the inside of the butter boxes; these effectually prevent any taste from the wood, and being a very poor conductor of heat, may assist in this way also to preserve the butter. The patentee, A. T. Peck, of Cortland Co., N. Y., adds a hinged cover, with a rubber band around the edge to exclude air. These boxes would answer well for keeping bread and cake moist. It is claimed that they can be made of all sizes, nearly as cheaply as good butter tubs or firkins. If as valuable as they appear to be, they should be largely manufactured at once, and an ample supply thrown into the market.

A Simple, Cheap, Convenient Pocket Filter for Soldiers and Others.

While crossing the ocean last Summer, the water brought up on one occasion was so roiled with sediment as to be disagreeable. An American lady of our company at once took from her reticule a little apparatus which could be packed in a large match box, and filtered the water perfectly clean from the pitcher into a tumbler. We tried to find one of these filters in London and Paris, but did not succeed. On coming home, we found them at a few places in New-York; but though said to be patented, we have been unable to learn the name of the patentee, or to find any one specially interested in bringing them before the public. We have therefore purchased one, and made the engravings at our own expense—for the benefit of the inventor, the dealers, and all concerned, and especially for our soldiers who are often obliged to go thirsty or obtain drink from filthy pools of water.



Figures 1 and 2 show the simplest form. *a* is a bit of artificial stone, 1¼ inches long, and ⅞ inch in diameter. This is firm, and apparently solid, yet the fine, imperceptible pores admit pure water through them. *b* is an India rubber tube, ¼ inch diameter, and a foot or so long, fastened into *a*, and fitted with a boxwood mouth piece, *c*. Placing the stone under water, (as in fig. 2), one can draw the pure clean fluid from a filthy roadside pool. As an experiment, we stirred flour in a glass of water, and yet filtered out clean water with this little instrument. It can be used as a syphon filter, (fig. 4,) to draw water from a cask, pitcher, or pail, into another vessel. To do this, immerse the stone, suck until the water is started, then depress the mouthpiece below the level of the fluid drawn from, and a stream of clear water will continue to flow. Another good suggestion, made by the artist, (Dr. Newberry,) while sketching the above, is, that a wounded soldier, having one of these tubes, can draw water from a tumbler or canteen, while lying upon his back, without raising his head. They are retailed at 50 cents each, and wholesaled somewhat less. The weight is less than 2 ounces; they can be packed to go by mail within 2 ounces, making the postage only 12 cents, under 1,500 miles. We have sent several to our friends in the army, and until they are on sale generally, will procure and send them, post-paid, to any address desired, for the retail price, (50 cents), as we can buy enough cheaper at wholesale to about cover the postage.

Fig. 3, is a new modification, just out, in which the rubber tube is about two feet long, and at *d* is fitted a cap with rubber washer, so arranged that by turning off a nut, and pressing the rubber washer firmly over the mouth of a bottle or canteen, (*e*,) the water, instead of passing on into the mouth, falls into the canteen. This will enable the soldier to fill his canteen with filtered water at pleasure. This form costs 75 cts. at retail, and weighs 3 ounces, making the postage 18 cents. We can forward them post-paid for about 80 cts. They are very desirable, but the lighter, cheaper form, fig. 1, will perhaps be as good for the soldier, who dispenses with every ounce of weight and inch of bulk possible. We have only spoken of them as being useful to the soldier; they are of course useful to any one having occasion to filter water for drinking.

High-heeled Shoes are Bad.

Can any tall person give a good reason for wearing high-heeled shoes or boots? In the case of persons of short stature there may be an excuse, if not a reason for the practice. Every one naturally desires to stand up to the average hight in community, and an extra inch of leather under the heel is perhaps as inexpensive a way of gratifying this vanity as can be devised. Yet it costs more than may be generally supposed—more we think than the benefit(?) derived can balance. The arrangement is clearly an unnatural one. The untortured foot of a child forms an arch, with the heel and the "ball" for the abutments, which rest squarely upon the ground. In the natural position, much of the weight of the body rests upon the key or top of the arch, which from its elasticity partly yields to the pressure, and thus acts like a spring to relieve the jar which walking, running, etc., would give to the whole frame. Now when one abutment of the arch, the heel, is raised from its proper level, the weight above is partly thrown from the top of the arch where it belongs, on to the heel, and thus the step is rendered less elastic, and more jarring is given to the frame. The increased shock is very slight, it is true, but the constant repetition of even this, which occurs in the every day exercise of the feet, will in time make itself felt. This is more to be apprehended from the fact that the spinal column which is directly affected by any such jar, is the most important center of nervous influence, and extremely sensitive to any unnatural treatment.

But even if no danger be feared from the above effects, there are palpable evils to the foot itself, resulting from wearing high heels. By their use the foot is forced forward into the shoe, crowding the toes against the leather, which very soon results in corns, bunions, in-growing nails, and all the evils which have called into existence the race of corn-doctors and chiropodists. This difficulty is still further aggravated by the absurd fashion of "stub-toed" shoes, which has been prevalent for sometime past. To prevent the foot thus sliding forward, shoemakers often fit the shoe tight upon the instep. This interferes with the free movement of the muscles and bones of the foot, impedes the circulation, produces cold toes, and general discomfort.

Another objection to high heels, of no small importance, is the danger from falls which they occasion. We have known several serious accidents caused by the heels catching upon the edge of a stair and sending the wearer headforemost down the whole flight. It is to be hoped

that all the readers of the *American Agriculturist* are so sensible as not to follow the absurd whims of fashion, yet some of their neighbors may be benefitted by the hints above given, if conveyed to them. A single layer of leather under the heel to receive the extra wear, is all that should be allowed, excepting in the cases of those very short people who can rise in the world by no other means; they may be permitted to suffer corns and risk their necks if they insist upon it.

Down Spreads Better than Cotton Comforters.

To the Editor of the American Agriculturist:

In a former number of the *Agriculturist* I noticed an objection to cotton comforters on account of their weight and bulk in washing, and lamb's wool blankets were recommended instead. I object to blankets because it takes so many to render a bed comfortable in cold weather. I would recommend down spreads, both for cheapness and convenience. Last winter I experimented with one down spread, containing one pound and a quarter of down, and two cotton comforters, each containing six bunches of cotton batting, and the result was, the down spread kept our bed warmer than the *two* comforters.

Now let us count the cost of each, saying nothing about the extra work to make the two.

1½ lbs. down $1.00 per lb.	1.25
16 yds. calico, 12½ cts. per yd.	2.00
1 bunch cotton batting	60
Total of one down spread	$3.85
6 bunches batting 60 cts. each	$3.60
16 yds. calico 12½ cts. per yd.	2.00
Total cost of one comforter	5.60

Lamb's wool blankets enough to make a bed comfortable in extreme cold weather, of course would cost more than either. A down spread is as easily washed as a single blanket, for when the down is wet there seems to be nothing of it. For the benefit of such as may never have seen this article, I give the directions for making.

Prepare the cloth as for any comforter, tack the lining upon the quilt frames, lay a border of cotton batting; now put on the outside, and tack it down around the edge; then quilt a line along the upper edge of the border to keep the down out of the cotton. Finish the border according to your taste, take it off the frames and bind it. Then baste the mouth of the sack containing the down around the space left in one of the seams of the spread shake the down from the sack into the spread, and when the sack is ripped off and the seam sewed up, the comforter is done.

In spreading it upon the bed, much trouble will be saved by shaking the down all to the front side, then spread it smoothly and put the outside quilt on before shaping the down; then gently pat it to its proper place as in shaping a light feather bed. A FARMER'S WIFE.

When to Peel Potatoes.

A subscriber asks of the *American Agriculturist* the decision of a mooted point between himself and wife, as to whether potatoes should be peeled before or after cooking. One party argues that it is necessary to remove the skins before boiling, to permit hurtful gases to escape, and to allow the water to enter the potato, to cook it thoroughly.

As to the gases, there need be no fear. Good sound potatoes contain no gas that is noxious. Instead of opening a way for the water to readily enter the potato, we think it desirable to keep it out as much as practicable. Potatoes contain water enough in their composition to answer all purposes for cooking, as is seen in the moist substance of a baked potato, which is generally conceded by almost every body to be better than the boiled article. Youmans, in his "Hand-book of Household Science," states that a pound of the substance of this vegetable is composed of about three quarters of a pound of watery juice, to two or two-and-a-half ounces of starch. The tissue of the potato consists of a mass of cells, each of which contains some 10 or 12 starch grains loosely situated and surrounded by the potato juice, which contains albumen. In cooking, the water of the juice is absorbed by the starch grains, which swell and often burst the cells. The albumen coagulates and forms irregular fibers. There is, then, no necessity for letting water enter the potato through openings made in the skin.

Even if potatoes boiled whole were no better than those peeled before cooking, economy would decide in favor of the former practice. Part of the substance is necessarily wasted by peeling raw. It also takes more time than after cooking. From these considerations we decide in favor of leaving the skins uncut until removing them from the pot. They will keep hot much longer if the skins are left until used at the table; but it is generally thought preferable to mash and otherwise prepare them before placing them before guests. *

Use More Corn in Cooking.

IMPORTANT HINTS TO ECONOMICAL HOUSEKEEPERS.

Will the ladies please look a moment at the Market Report, and note the difference in the selling price of a bushel of Wheat and a bushel of Indian Corn. In the New-York market, at the time of this writing, the best white wheat is quoted at $1.47 per bushel; the best corn at 64 cents per bushel.—Now we hesitate not to say that, after grinding and bolting, a bushel of corn will furnish fully as much solid nutriment as a bushel of wheat; that is, $1 expended in corn will buy as much nutriment as $2.30 expended in wheat. As the cost of transporting a bushel of corn is about the same as for a bushel of wheat, the difference in favor of the corn is much greater at the West. Thus, at a point distant enough to make the cost for transporting a bushel 47 cents, the wheat would be worth $1, and the corn 17 cents—a difference of nearly six to one in favor of consuming corn and selling wheat.

Another fact should be remembered. Europeans want all the wheat we can spare, and will pay a fair price for it. As they have grown little corn, they have not yet become accustomed to its use. And still further, corn does not bear transportation in ships as well as wheat, which operates against large exports of the former. Corn contains more oily food than wheat, and is therefore quite as well adapted for food during the six or seven colder months of the year, when heat producing food is required. The only difficulties in the way of the more general use of corn, is the prejudice against it, and the comparatively little attention given to the best modes of cooking it in palatable, digestible food. We again urge our fair readers to look into this matter. Try different recipes, until some one or more methods are found which prove palatable to the family, and are economical withal. Some of the methods of cooking corn meal in vogue, require a considerable admixture of eggs, milk, etc., which diminishes the economy, though it is to be remembered that a larger application of butter, or gravy, is required on good wheat bread than on good corn bread. As a rule, the butter in a family costs more than the flour. In the *American Agriculturist* for January and February of this year (1863), may be found over a hundred different modes of cooking corn meal, including the prize recipes. Now that cold weather is approaching, we urge our readers to turn back to those directions and see if they can not select some good methods by which they may largely increase the use of the more economical corn in their families.

Good and Cheap Corn Bread.—E. Dickerman, of Middlesex Co., Conn., contributes the following to the *American Agriculturist*, with the remark that he thinks it will be found quite as good as any thing yet published. "We have had it put to practical test, and can endorse it as very good.) Mix thoroughly together 5 cups Indian meal, 3 cups wheat flour, 5 cups sweet milk, 2 cups sour milk, 1 cup molasses, ¾ tablespoonful soda, (first dissolved in the sour milk), 1 tablespoonful salt. Bake in two deep pans for 2 hours. Half the above quantities will be enough for a meal for an ordinary family.

Corn Breakfast Cake.—A housekeeper contributes the following to the *American Agriculturist*, with a sample of the result for the editor, which he pronounces "not bad to take." The writer says: "My cook, Kate, is to be credited with the mixture if you like it": Mix well by sifting, 1 pint Indian meal, 3 tablespoonfuls wheat flour, 1 tablespoonful sugar, 1 teaspoonful salt, 1 teaspoon ful soda, and 3 teaspoonfuls cream of tartar. Mix rapidly and thoroughly with 1 pint sweet milk, 1 beaten egg, and butter the size of an egg. Bake in a shallow pan, 20 minutes, in a hot oven.

Important Hints on Cakes and Biscuit Making.—An old contributor of good hints to the *American Agriculturist* gives the following. They stand to reason: My observation is, that very few housekeepers are aware of the importance of *thoroughly mixing* the ingredients of cakes, biscuits, pie-crust, etc. Where salt, soda, and cream of tartar, are used, a little more of one material is usually left in one part of the flour than in another, and unevenness of taste or lightness, is the result. It is always better to put all dry materials into the flour or meal dry, and mix them well, then always run the whole over once or twice through a sieve before wetting. All lumps are thus broken up, and the mixture is uniform. Let the wetting then be done with all materials cold. Let it be done rapidly and thoroughly, and just before baking. If put into a hot oven at once, the outside is hardened and retains the gases to make the whole light. The after baking should be rapid, but not so much so as to burn the crust; the point is to harden the shell at first before gases escape. Heat liberates these gases rapidly; hence the direction to mix the materials cold.

Biscuits—Crackers—Rolls—Amusing Mistake.—An amusing instance occurred during our stay in London, the past Summer. The English people do not use the term "cracker" as applied to food. They use the general word "biscuit" for all kinds of hard bread, such as are called by us crackers, sea-bread, etc.; while they call our biscuits and other small bread by the general term of "roll"—as breakfast rolls, tea rolls, etc. A lady traveling friend of ours sent out the servant to procure a couple pounds of "Soda crackers" for tea. She was gone a long time, and finally came back with her basket saying that she had been all over and could find no "Soda crackers," but here was the nearest thing to them she could get. On opening the basket it contained two pounds of *fire crackers!* If our friend had sent for soda biscuits, the soda crackers would have been quickly procured at the nearest baker's. This happened near the 4th of July, so that the mistake was not very *mal apropos*, after all.

Good Tea Biscuit without Milk.—The following, contributed to the *American Agriculturist*, we know to be good, having tested excellent samples of the biscuits, or rolls, produced: Mix and *sift well together*, 1 quart flour, 1 teaspoonful soda, and 2 of cream of tartar, with salt to taste. Use butter the size of an egg, and water only to mix it of proper consistence.

Vinegar Recipe.—A correspondent of the Scientific American says: "To one gallon of soft water, add a pint of sugar, or sorghum molasses, stir all well, and then add nearly a gallon of tomatoes, fresh and ripe. Then set the vessel aside, and in a few days you will have the sourest pickles I ever tasted, and nearly the best vinegar."

Cement for Roofing.—"J. L." of Setzler's Store, Pa., inquires how to make a good cement for roofing. We suspect a good many *manufacturers* would like to know the same thing. The article is in the market in great variety, but we know of nothing that we should like to recommend. A good shingle, slate, or well painted metal roof, is generally cheapest in the long run.

The Editor with his Young Readers.

LETTERS FROM MR. JUDD....NO. III.

(*Concluded from page* 313.)

[Below is a small portion of the outline map of London, but it will be better for all to read what follows with last month's full map before them. The maps are drawn to a scale of about a mile to each five-eighths of an inch.]

The large white spaces *N, O, H, W,* represent the four largest Parks of London. These are really grand parks, occupied by small forests and clumps of trees, large grass plots (some containing dozens of acres,) walks, carriage drives, artificial lakes and ponds, etc. There are several smaller parks of a square or so, with trees and grass plots.

Hyde Park, N, is one of the most noted of London. Its Western end is called Kensington Gardens, or Park. Hyde Park contains 388 acres, and Kensington Garden 356, or in both 744 acres. As they join together you will see that here in the midst of London is an open "breathing place" as large as five farms of about 150 acres each. An artificial lake or river nearly a mile long and averaging about an eighth of a mile wide, lies nearly in the middle, curving around towards the northwestern side. On this are pleasure boats in great numbers, and on fair days thousands of people are seen around its sides. Along the south side of Hyde Park is a broad carriage drive, where a great number of the wealthy classes ride out in their splendid carriages, from 4 to 6 o'clock, P. M. Just north of this is a long drive where gentlemen and ladies ride on horseback; though a beautiful road it has the ominous name of "Rotten Row." Broad lawns intersected by gravel walks and drives, and beautiful groves, occupy Hyde Park. (The old Crystal Palace of 1851, stood near the southeast corner. This was taken down and removed 7 miles south, to Sydenham, where it fronts upon a magnificent park, grand fountains, play-grounds, etc. The International Exhibition of 1862 is at *P*, on our map. This is not a Crystal Palace; its walls are of brick, but most of its roofing is of glass.) Kensington Garden or Park (*O*), has many trees, with wide avenues or streets between them. It has one quite large forest of old trees, in the tops of which I saw a flock of thousands of crows, apparently at home, though almost in the city. Hardy trees from all parts of the world are growing in Kensington Park, and almost all varieties of hardy trees, shrubs and plants grow along the double border on the south and west sides. These trees and plants are labeled with the common and botanical names, and with their origin, so that one can here studythe arboriculture and much of the botany of the rest of the world.

Regents Park (H), containing 472 acres, is another fine rural place in the northwest part of the city. This has larger lawns with cattle and sheep grazing, a very irregular lake with small islands, a botanical garden, a drive around it 2 miles long, some villas, etc. The most interesting portion to me, is the noted Zoological Gardens (*J*) in the north part. There are hundreds, perhaps thousands of animals, birds, water fowls, reptiles, etc., gathered from various countries, and living here as nearly natural as may be. The lions, tigers, bears, and other fierce animals are in large cages. The fowls and birds are in spacious yards or enclosures surrounded on the sides and above with wire netting. Pelicans, Ostriches, Swans, Birds of Paradise, Elephants, Rhinoceros, Zebras, all kinds of deer, grouse, all kinds of monkeys, seals in ponds—In short most of the beasts, birds and reptiles known, are kept alive in these grounds. I spent a whole day among them and was not half satisfied. I am sorry to have so little space to tell you about them.

Victoria Park (W), or old "Bethnal Green," in northeastern London, is shaped somewhat like a stocking, and contains 265 acres (a large farm). This is a great play-ground without many walks or drives. On a Summer afternoon there are sometimes 30,000 to 40,000 people here, engaged in cricket, archery (bow and arrow shooting), and other games and sports.

St. James Park of 91 acres, shaped like a boy's kite, lies east of and adjoining the Queen's residence, or Buckingham Palace (*M*). This has a beautiful lake, exquisite gardens, etc., which I have not room to describe. *Green Park* of 60 acres, mainly an open green lawn, lies around and west of *M*, cornering on Hyde Park. These parks, and the smaller ones not referred to, contribute much to the health of London, and add to the beauty of a city which would otherwise be gloomy indeed.—I should have noticed *Battersea Park (R),* an open space of 185 acres on the south side of the Thames river. It is mainly a play-ground where thousands of persons play cricket or "ball," and other athletic games. In a portion of this was held the great Show of the Royal Agricultural Society of England, one of the leading attractions that brought me here this Summer.

The Bank of England (A), is about ¼ mile north of London bridge, and is the great commercial center of the city. The building is massive, low, and its rooms and courts cover about 4 acres! It contains constantly from $85,000,000 to $90,000,000 in gold, and circulates notes to the amount of $70,000,000. These notes are larger than ours; they are very plain, having but few words, or pictures on them, but are printed on a peculiar paper; each one is numbered, and never re-issued, the old notes being destroyed whenever they come back to the bank, and new ones sent out. The specie, when received and paid out, is counted into scales and weighed instead of being counted. There are some 900 clerks who receive over $1,000,000 in salaries; yet the bank makes a clear profit of about $125,000,000 a year, which is paid in dividends.

St. Paul's Cathedral, or Church (C), is nearly ¾ mile north of the river, and ½ mile west of the bank. It is of stone, 500 feet long from east to west, the main part about 100 feet wide, with a transept under the dome, east of the middle, making the ground plan somewhat like a cross. Two turrets or steeples on the west corners are each 222 feet high. The central dome is 404 feet high to the top of the cross, which stands upon a ball. This ball looks very small, yet I went into it with three other persons, and by a little crowding as many more could have found room. The dome and the whole building are so massive and well proportioned, and so surrounded with other buildings, that the Church does not appear large, except when seen from a distance on a clear day; then it looms up above the city in all its grandeur. There are a number of statues and monuments within and under the church. Lord Nelson is buried here; also the Duke of Wellington, and other eminent persons, warriors and statesmen, but no divines, as one would expect to find. One can go all over the church, on paying 3*s.* 2*d.* (about 78 cents).

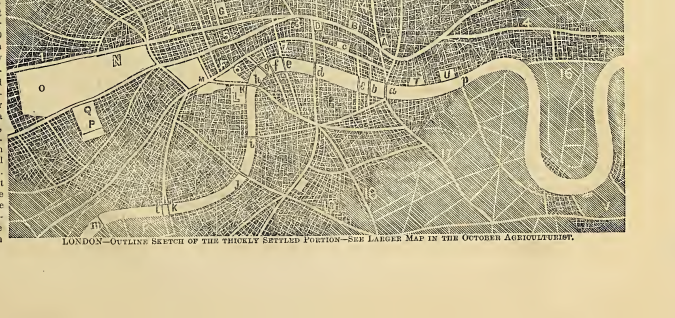
The House of Parliament (K), is on the west side of the northern bend of the Thames, about 2 miles above old London Bridge. Its river front is 900 feet in length, adorned with rows of statues, paneled tracery, shields, etc., all cut in stone. On the southwest end is a tower, 75 feet square and 340 feet high. A central spire is 60 feet in diameter and 300 feet high. The Clock Tower on the northern end is 60 feet in diameter and 320 feet high. The clock face is 30 feet across. The building covers nearly 8 acres, contains 1100 rooms, 100 stair cases, and more than 2 miles of corridors or halls. There are nearly 500 statues in the building, of stone or marble, and a great number of paintings. The first stone was laid in 1840, and the whole structure cost over $10,000,000. The House of Lords or Peers, and House of Commons meet in two rooms,—the former 97x45 feet, and 45 feet high, profusely decorated in gold; the latter 62x45 feet, 45 feet high. The members of Parliament meet towards evening, and sit until after midnight. They sit with hats on, on long seats without writing tables or desks. A ticket from the American Minister admitted me to hear the debates.

Westminster Abbey, at *L,* near the Parliament Houses (*K*), is to many persons one of the most interesting places in London. It is a very old Church, founded in A. D. 616, or 1246 years ago. All the kings and queens of England, since its founding, have been crowned in this church, and most of them have been buried in it, together with many eminent statesmen, divines, literary men, poets, and generals. The walls are covered with portraits and statues of those buried here, and of historical scenes painted on canvas, or cut in stone or marble. There are nine little side chapels or rooms, containing the remains of kings and others, most of which have tombs or tomb-stones, some of them very elaborately carved, and some very grotesque. I recall the tombs of several King Edwards, and Henrys, and James; Mary Queen of Scotts, Queen Anne; Lords Clarendon, Chatham, Pitt, Fox, Canning; the Poets Chaucer, Dryden, Addison, Sheridan, Campbell; the Musician Handel, etc.

Buckingham Palace (M), is Queen Victoria's city residence. (Her country residence is at Windsor Castle, or Palace, on the Thames, a few miles west of London, where she spends the greater part of the year. I visited the farms of the late Prince Albert, near Windsor. Buckingham Palace is ¾ mile west of the Parliament Houses. It is like a large dwelling house, with many fine rooms, paintings, and statuary. People live, eat, and sleep there, just as they do in other houses, having rather more costly furniture, and a larger retinue of servants. Around the palace are beautiful grounds, groves, artificial lakes, statuary, fine walks, etc.

The British Museum (G), is the most interesting of all buildings in London. It is an immense square structure, with a great number of rooms filled with a vast collection of different objects. There are here more than half a million books, besides old manuscripts, and parchments, works of art, minerals without number, Layard's collection from Nineveh, others from Egypt, preserved animals of all kinds, etc., etc. It would be useless for me to attempt to describe this museum. One could spend weeks here without examining all the things to be seen.

The Tower of London (T), is on the bank of the river, ½ mile east of London Bridge. This is more a fort or castle than a tower. It consists of a little over 12 acres, enclosed by high, thick walls, and a deep, broad ditch or moat. Inside of this is another wall, with low towers at its angles. Within the enclosed large space is a long row of soldiers' barracks on the north side. About the middle is the "White Tower," or simply a massive stone building which contains several rooms filled with old armor, coats of mail, spears, battle axes, guns, pistols, etc., representing the kinds of armour and weapons in use in different periods of the past. Here are also the old instruments of torture, beheading axes, blocks, etc. In the center of this is a dark dungeon or cell where some noted persons have been confined. In the northeast part of the enclosed space is a small, but heavy-walled building, called the "Jewel Tower," in which is kept the Crown of England, in a large, high glass case, with other lesser crowns, diamonds, jewels, golden vessels for royal baptisms, etc. Visitors go all through the tower, and see the armor, crown, etc., on paying 25 cents. On the northwest side, forming a part of the inner wall, is an old prison room, where Lady Jane Grey and other eminent persons were incarcerated. Looking out of the window to the open space, you see the place where she was beheaded. The ax, and the block with the deep cut made by the ax, are preserved in the White Tower. In some of the rooms of the Castle or Tower of London,



LONDON—OUTLINE SKETCH OF THE THICKLY SETTLED PORTION—SEE LARGER MAP IN THE OCTOBER AGRICULTURIST.

WHICH IS THE TALLER?—*(Engraved for the American Agriculturist.)*

Thoughts Suggested by the Picture.

What boy does not wish to be a man? Certainly not the one in the picture. He is anxious that his grandmother shall think him a large boy, much larger than his cousin. They have already measured once, and John stood an inch highest, but his grandmother remembered that John's shoes had high heels, while Kate's had none. So both took off their shoes for another trial. Kate does not seem to care much if John is taller, for she takes no pains to hold up her head; but see how John straightens up, and the rogue is on tiptoe, which his grandmother does not perceive, so she thinks he is really outgrowing Kate, although she can hardly believe her eyes. John is as much in play as in earnest, as you can see by his roguish look, but boys often try to deceive others into an acknowledgment of their manliness, much to their own harm. Some make the great mistake of supposing it is manly to disobey their mothers: "breaking away from mother's apron string" they call it. Breaking their mothers' heart strings they should say, for that is what a disobedient boy has commenced to do.

The man who stands foremost in the history of this nation, the immortal Washington, up to the day of his death, showed the most sincere veneration for, and affectionate obedience to his mother. It is related that at one time they were attending a ball given in his honor at Philadelphia, and when 10 o'clock arrived, his mother took his arm, and said, "Come, George, it is time to go," and the great man immediately accompanied her from the crowded assembly. This filial obedience in good part made him what he was. Had he thought it manly to have his own way, he would have been an officer in the British navy. When a boy he was about to enter that service as midshipman. His mother, seeing his heart set upon it, had given a reluctant consent. Every thing was ready, and he was about to start, but he saw the grief of his mother, and refused to disobey even her wish.

We have seen boys trying to be manly by smoking, swaggering, and even swearing. What a mistake they make. (The veriest coward can easily practise such vices: but it requires a courageous, manly boy to maintain a good character, particularly if surrounded by bad examples.) Such boys deceive only themselves. No one else thinks them one inch taller or one whit more like men.

Who can help liking the sweet, mild countenance of little Kate, in the picture. She is content to appear just as she is, and is entirely willing that her cousin shall pass for her superior. She gains much more by her humility than he does by his trickery. And so you will find it in life. Those who are content with appearing just as they are, will escape criticism and secure favor; while those who try to seem great, will only deceive themselves and make enemies among those around them.—Remember well, that a habit of deception grows from small beginnings. John, in the picture, is playing deception now. Another time he will verge a little upon actual deceit; another time he will go further. Keep your conscience sensitive by avoiding the slightest act like deception.

---

have been confined, and some of them beheaded, many persons noted in England's past history—Wallace, Mortimer, King John, Queen Anne Boleyn, Cranmer, and others, Kings, Queens, Princes, Bishops, Generals, etc.

Thames Tunnel (at *p*), is still a curiosity, though pecuniarily a failure. You pay a penny (2 cents), go down a great circular room by 100 stone steps around the wall, and then through an arched passage 1200 feet long, under the bed of the river. The passage is large enough to drive a large load of hay through. Another similar passage way by the side of it is not used now. Between these are pillars, and between these pillars are about a hundred shops, where are sold toys, trinkets, refreshments, etc. The bed of the tunnel arches upward a little in the middle, so that you can not see through the whole length. At the other end, you go up a hundred steps and land on the opposite bank of the river. The walk is cool, not so damp as I expected to find it, and one feels a kind of thrilling sensation when walking under the river, with perhaps great ships floating directly over his head.

Woolwich Arsenal and Navy Yard, corresponding to our Brooklyn Navy Yard, is on the south side of the Thames, 4 or 5 miles below Greenwich. *At Greenwich*, (*Y*), I visited, besides the celebrated Observatory before referred to, a large Naval Hospital, where the government provides a home for her worn out and wounded seamen. Some old soldiers are here also. I was much interested in seeing 1300 of these old men, a majority of them crippled, gather into the great dining halls, and there receive their noon "rations,"—a basin of meat and soup, and a large piece of bread for each. In a chat with one of these old men who had spent 38 years in the English army, it came out that he was, during the war of 1812, in the very battle in which my own uncle, after whom I was named, was killed, and in which my father escaped death by the ball aimed at his breast being glanced off by his musket stock in front of him. The meeting was a strange coincidence surely! In this hospital are some of the finest paintings of battle scenes, of warriors, of soldiers leaving their homes, and of deaths of generals and commodores, and singularly enough, some of the best of these, so acknowledged by all, were painted by our own countryman, Benjamin West, who when a boy began with charcoal sketches in Philadelphia.

Billingsgate, the great Fish Market, on the river just below London Bridge (*b*), is in one sense interesting to a visitor, at 5 or 6 o'clock in the morning. A great number of men and women are then selling fish for other markets, and the loud noise and foul language heard, especially from women, gave origin to the word "billingsgate," now used to designate any foul, slanderous talk.

City Road, (14, 14,) running north from the Bank, and bending round west, furnished an interesting walk. On the west side, at the lower fig. 14, is the old "*Bunkill Fields Burying Ground*," of less than 4 acres, in which have been buried **107,416** persons whose names are registered, besides many others not recorded! I noticed here, among others, the graves of John Bunyan, author of Pilgrim's Progress, Isaac Watts the Poet, and George Fox, founder of the Society of Friends or Quakers, and Mrs. Susanna Wesley, mother of John Wesley. Nearly opposite is the old "Foundry Chapel" or City Road Chapel, where John Wesley founder of Methodism preached. In the small grave-yard adjoining lies John Wesley, Drs. Adam Clarke and Benson the Commentators, etc. (I had an interesting visit to Radnor-street Sabbath School connected with this church, but ½ mile northwest, in a building erected for the school, where 1800 children attend the Sunday and week day schools. I tried to go in unrecognized, just to see *how* they conducted so large a school, but they *guessed* me to be an American, and insisted upon a speech. At their urgent request I talked a little of the war in America, and why and for what we of the North were fighting. The feelings and sympathies expressed by about 200 teachers, and over 500 larger bible scholars who gathered around me, are among the most pleasant remembrances of London, where an American usually finds so little sympathy with his own country in her troubles. The same afternoon I visited the "Field Lane Ragged Schools," at a place not far north of the Post Office (*D*). It was most pleasing to see so many ragged children, and abandoned men and women, brought together and instructed. Better order, or more diligent attention I never saw among any gathering of children. I can not describe several churches I attended, such as Rowland Hill's Chapel, on Blackfriar's Road, south of the bridge (*d*), now occupied by Rev. Newman Hall. Spurgeon's Church, as before stated, is still a little further south. The Church of Dr. Punshon, (the most eloquent preacher I ever heard) is in Highbury, in north London. Dr. Cummings' church is close by Covent Garden Market, near the figure 7 on the map, Covent Market is noted for its flowers, fruits, and vegetables.

But I must close. I would like, if I had room, to tell you much more about the things already described; about the general Post Office (*B*), and the way they gath er up letters and deliver them to the houses in every part of the city, and every where in Great Britain, for a penny (2 cents), not waiting for anybody to go to the Post Office, or to look for their letters, about the Royal Horticultural Society's new grounds at *Q*; the bridges over the Thames, from *a* to *m*; about old Newgate Prison at *D*; about the East India Docks, at 16, which extend across the bend of the river (leaving the "Island of Dogs" in the bend); and about a hundred other things that crowded upon my mind. But I must leave London, and perhaps tell you briefly about Paris, and things to be seen in France, Switzerland, Germany, and Belgium.

Peter after a Rabbit.

A reader sends the following to the *American Agriculturist*. Two boys, Peter and Lemuel, live in the same neighborhood. One of Lemuel's friends, gave him a beautiful tame rabbit, curiously marked with white and black, to which he soon became greatly attached. He was never tired of feeding and petting it, and exhibiting it to his playmates. Peter often visited Lemuel and played with the rabbit, but this did not satisfy him; he wanted it for himself, and tried to buy it, but Lemuel would not part with it. After long coveting, he took the next step, and resolved to steal what he could not get otherwise, probably thinking he would keep it for a day or two, and then pretend it came to him of its own accord. So one night, just at dark, Peter went cautiously to the garden and crept along through the currant bushes towards the rabbit's kennel. Before reaching it he saw his supposed prize cross the path just before him, and eagerly pouncing upon it, grasped it tightly in his arms. But instantly he was almost suffocated with the odor of a young *skunk* which he had mistaken for the rabbit. To add to his chagrin, just at that moment Lemuel's father perceiving the smell, ran from the house and caught him as he was running through the gate. The story was soon known, and Peter and his rabbit became a byword in the village.

A Horrified Dandy.

A laughable incident is related of a dandy who was seated on the balcony of a Saratoga hotel, among a large company. He was exquisitely dressed and very highly perfumed with musk, which is very disagreeable to some persons. A plain farmer happening to pass near him, commenced snuffing suspiciously, and looking around for the cause of the musky effluvia, he soon smelt out the dandy, and thus addressed him: "I say mister, I can tell ye what'll take that smell out of yer clothes. Just bury 'em under ground for a week. My uncle run agin a skunk once and he"—— but before the sentence was finished the enraged dandy sped from the crowd to escape the shouts of laughter, while the innocent farmer who only meant to do him a kindness, was wondering what caused his sudden departure.

"Blue Hen's Chickens."

We have long known that the people of "little Delaware" were called "Blue Hen's Chickens," but could not tell why. At our request, Rev. Dr. Coombe, of Philadelphia, a native of Delaware, furnishes the explanation for the *American Agriculturist*, as follows; In the olden time there was in that State a breed of fighting cocks, noted for their pluck and endurance. They never knew when they were whipped, but would fight on as long as there was a feather left. The only account of the origin of this breed was that they originally sprung from a blue hen.—In the Revolutionary war (1776–83), Delaware furnished a regiment of soldiers, which in numerous marches and battles became distinguished for persistent bravery. On this account they came to be called the "Blue Hen's Chickens." The name thus becoming an honorable one, was afterwards assumed by the people of the State.

Curious Change of Names.

A Scotchman named *Feyerston*, settled among some Germans in Western New-York. They translated his name into *Feuerstein*. On his return to an English neighborhood, his new acquaintances discovered that *Feuerstein* in German, meant *Flint* (Firestone) in English, and thus retranslating it, his descendants are called Flint to this day. A grandson removed to a French settlement, where they called him in French, *Pierre, a Fusil*, and his son removing again, was renamed in English, Peter Flint.

A Cool Soldier.

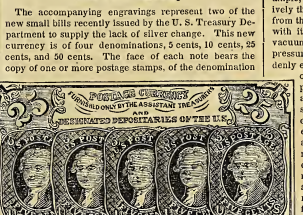
During one of the recent battles, while a regiment of our troops were rapidly marching over a dusty road in changing their position on the field, a soldier noticed a cake of soap at a little distance from the rank, and sprang forward to get it, saying "I shall need it after this fight." The shells of the enemy were falling thickly, and just as the soldier seized the soap, one dropped close by him and exploded, tearing open an immense hole in the earth and nearly burying the poor fellow. Every one supposed he was blown to pieces, but almost immediately he struggled out, begrimed with dirt from head to foot, yet holding on to the soap, and exclaiming, "There, I told you I should need it!" Fortunately he passed through the battle unhurt, and found his well earned soap a great convenience.

An old Illustration, but a Good One.

Two painters were on a high scaffold, in a magnificent Cathedral, frescoing the wall. The master artist had executed a sketch so beautifully that he was completely charmed with it, and while gazing upon it he insensibly walked backward to the very edge of the scaffold. His comrade saw his danger, but feared to seize hold of him or even to speak, lest he should start him back to certain destruction. He had the presence of mind to dash the wet brush in his hand against the entrancing picture. The artist sprang forward, and was in great rage, until he was informed of his narrow escape.....Just so we get absorbed with some object of our affections, and step backward from our upward pathway, unconscious of our peril; then a kind Providence dashes out the beautiful image, to awaken us from our dream-like state, and bring us to a sense of our danger. Thus it is that our nearest friends, or our most cherished earthly possessions, those we are loving too well, are often taken away in mercy.

The New Money.

The accompanying engravings represent two of the new small bills recently issued by the U. S. Treasury Department to supply the lack of silver change. This new currency is of four denominations, 5 cents, 10 cents, 25 cents, and 50 cents. The face of each note bears the copy of one or more postage stamps, of the denomination



shown by the small figures. On the back of each note is a larger figure, showing the exact value in cents, and the inscription: "Exchangeable for United States Notes by any Assistant Treasurer, or designated U. S. Depositary, in sums of not less than five dollars. Receivable in payment of all dues to the U. States, less than five dollars. Act approved July 17th, 1862."—These notes are now being distributed in exchange for those of larger denominations, at the U. S. Treasury Offices in Washington, New-York, and Boston, and will soon come into general use. Silver is so scarce that they are in great demand.

"Shall I Learn to Dance?"

Asks a young reader of the *American Agriculturist*. Certainly, by all means. Commence with the "Quick-step" out of bed in the morning, and keep it up until the "chores" are finished. The boys will of course have a "*cow-drill*" at the barn, while the girls are engaged in a "*country-dance*" in the kitchen. After this, all hands "change," and promenade to school, keeping step to the music of merry laughter. Repeat the same on the way home at night, with an occasional variation in Winter by "tripping the toe" and having a "break-down" in a snow bank. A "reel" now and then will be quite in place for the girls who have learned to spin, but the boys should never think of it. If these and kindred dances are thoroughly practised, they will leave little time and no necessity for the polkas, schottisches, and other immodest foolories of the ball-room.

The Pugnacious Ram.

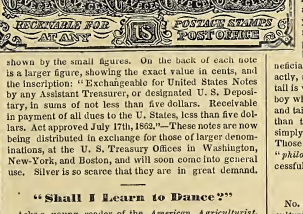
John B. Gough, in one of his eloquent temperance lectures, was encouraging those who signed the pledge to stick to it: "Stick to it," said he, "as the old ram did to his butting." The fable is, that a farmer had a ram which would run his head against the cows, horses, pigs, and indeed against every thing in motion. The farmer himself was more than once butted over, and he finally determined to break up this propensity. So he tied a heavy block of wood upon a rope, and hung it on the limb of a tree. The block was set in motion, and the ram, seeing it move toward him, hit it a blow. This sent it off, but it swung back, when the ram hit it again, and so kept on doing. The farmer watched him until it was dark, and then left him, true to his nature, butting away. Early in the morning, on going out to see how the ram had fared, he found that he had butted himself all away, except a part of his tail, and that was hammering away at the swinging block.—That's the way to stick to your pledge.

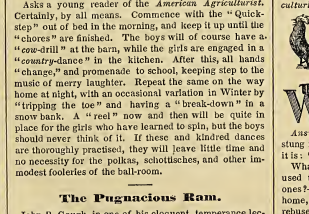
A Funny Mistake.

A little boy asked his mother, what "blood relations" meant. She explained to him that it signified near relatives, etc. After thinking a moment, he said, "Then, mother, you must be the bloodiest relation I've got!"

The Quill and Card Experiment.

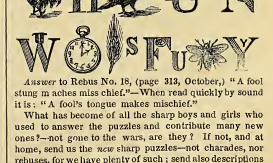
Several of our young readers have sent explanations of this interesting experiment, which was described in the September *Agriculturist*. They agree in saying that the air which is compressed by being driven through the quill, suddenly expands on issuing between the disks, and rushing out in all directions carries with it part of the air separating the disks. This causes a partial vacuum, and the pressure of the air upon the surface of the upper card is greater than that below it; consequently, the card is forced toward the quill, instead of being blown away. Willie Carrington writes that something similar occasionally occurs during hurricanes. For example, when the sides of a barn roof face respectively the North and the South, if a hurricane comes from the North, as it rises over the roof, it carries with it a portion of the air, thus creating a partial vacuum on that side. This partly removes the pressure from without, and the air inside suddenly expands and forces outward the northern portion of the roof. He also describes the following experiment, illustrating the same principle, which any of our young readers can easily try for themselves: Take a piece of thin paper, about ten inches long and two inches wide, and paste the two edges together so as to form a long tube. Insert a cork into one end of this tube, and thrust a common goose-quill, open at both ends, through the cork. The engraving shows the proper arrangement. Now blow hard through the quill, and instead of seeing sides of the paper swell out, as might be expected, you will find that they are forced together by the pressure of the outer air; and they will continue in that position as long as you continue to blow through the quill.—There are many of these philosophical toys, which are both pleasing and instructive. Anything that leads a boy or girl to think, to study into the "*why*," is beneficial. Very few of the boys who fly kites, can tell exactly, *why* the kite rises. The length and weight of the tail is with them a matter of necessity or trial. The boy who looks into the triple action of the wind, string, and tail, and understands them, can make a better kite, than the thoughtless one, who constructs his kite by simply imitating others. It is just so in everything else. Those who in childhood and youth learn to study into the "*philosophy*" of their toys, will be the thinking and successful men and women, when grown to adult years.





Problems and Puzzles.

No. 10—*New Rebus*, contributed to the *American Agriculturist* by W. B. Maccracken, Lancaster, Ohio.



Answer to Rebus No. 18, (page 313, October,) "A fool stung m aches miss chief."—When read quickly by sound it is: "A fool's tongue makes mischief."

What has become of all the sharp boys and girls who used to answer the puzzles and contribute many new ones?—not gone to the wars, are they? If not, and at home, send us the *new* sharp puzzles—not charades, nor rebuses, for we have plenty of such; send also descriptions of new amusements, and anecdotes occurring in your different neighborhoods.

CHILDREN should be well cared for at all seasons of the year, yet in Winter we think it well to "*let them slide.*"

BEAUTIFUL EXTRACT—helping a handsome lady out of a mud puddle.

Is that farmer a ride man who pulls the *ears* of Corn?

"It is said" that in Denmark carriage horses are taught to step high by the substitution of magnifying glasses for blinkers. They mistake every pebble for a boulder, and lift their legs accordingly.—Who says so?

Ram is too good a target to be worn in war. Military and scientific men have decided that soldiers dressed in red are hit 13 times in battle, where those in Austrian gray are hit only 5 times.

Hides are said to be tanned in a few hours by a new process. Our old schoolmaster used to do it effectually in two minutes. We of course speak from observation—not from experience!

"Wake up, here, and pay your lodging," said the deacon, as with the contribution box he nudged a stranger sleeping in a pew.

The road ambition travels is too narrow for friendships, too crowded for love, too rugged for honesty, and too dark for science.

He who swears shows plainly that he distrusts his own word, and thinks others will do so if he does not confirm it with an oath.

There's a plenty of ups and downs in this life. Pendergast once ran for constable, and the next day a constable ran for him. The last ran he got in.

None have been so good, or so great, but have raised themselves so high as to be above trouble. Our Lord was "a man of sorrows."

A poultry fancier lately procured a picture of a favorite hen, which was so natural that it laid on his table every day for several weeks.

DEATH is the only master who takes his servants without inquiring into their previous character.

Fast horses win cups by the use of their legs. Fast men lose their legs by the use of cups.

The man lacks moral courage who treats, when he should cheat.

The wasp attacks the ripest fruit first, so will slander attempt to wound the most honest fame.

A horse that kicks, if he does not bite, is like a crazy old gun—more dangerous at the breech than at the muzzle.

By preparing for the worst, we often secure the best.

A Crooked Nose is but for every man follows his nose.

PREMIUM LIST,

For 1863---Volume XXII.

New Subscribers get the Rest of this Year Without Charge. (*See page* 352.)

Good Pay to Voluntary Agents who attend to Collecting and forwarding Clubs of Subscribers to the American Agriculturist.

(Premiums open to all who Desire them.)

Every subscriber is invited to renew his own subscription, and to solicit others to subscribe. But to all those who will take the trouble to collect and forward clubs of subscribers, we offer a remuneration in the form of *first-rate* articles, as named below. The pay thus offered is much larger than we could pay in cash, though no article is proposed which is not of the best quality, and fully worth the price asked. (We get these articles on extra good terms *when for premiums.*)

Part of the Premium articles announced this month are selected from the best given last year, those which gave universal satisfaction. They are such as will *pay* for the effort to obtain them.

☞ WE WISH IT DISTINCTLY UNDERSTOOD *that these premiums are offered in good faith—no cheap, trashy, imperfect, poorly made, or second-hand thing, will be sent out, but each article offered, is the best of its kind, and every one will be selected by the publisher from the very best manufactured. They will be the best sold in the market at the prices named.*

☞ We offer nothing *for competition.* Each premium is for a specified number of subscribers, and no one's remuneration will depend upon what other unknown persons are doing; every one knows just what he or she is working for.

☞ *We make no distinction between new and old subscribers* in giving these premiums, but it is expected that every canvasser will not only gather up the names of old subscribers, but also secure a large number of new names.

☞ Every person collecting names for premiums, should send two copies of each list of names—one of them marked "For Premiums," and also with the name of the sender.

☞ Every person collecting names for premiums, should send the names with the money as fast as obtained, so that the subscribers may begin to receive their papers; but if designed for premiums, two copies of each list of names should be sent—one of them marked at the top "For Premiums," and also with the name of the sender.

☞ The premiums are offered for subscribers for Volume XXII (1863), *whenever received.* Canvassers will have time for completing their lists, but the premium will be paid as soon as any club is made up—if duplicate lists are sent.

☞ Any person who has commenced sending in names at 90c. and finally fails to get the higher number of names, can fall back upon the smaller number, by remitting the 30 cents extra on each of the smaller number of names required. ☞ Clubs need not be all confined to one Post Office.

Table of Premiums for 1863.

Names of Premium Articles.

Price of Premium.	Names at 90 cents each.	Names at 80 cents each.

26—Family Lard and Wine Press	$7 00		34

Specified in Premiums.

DESCRIPTION OF THE PREMIUMS.

Premium No. 1—Good Books.

This premium will meet the wants of a great number of persons. On page 351 is a list of 58 books, many of them on topics connected with the Farm, Garden, and Honsehold, and a portion of them the very best published. (See remarks in that list.) Any of the books may be ordered, and 16 or more subscribers, may select any of the books in that list, (page 351,) to the amount of 12½ *cents for each name, at the club price of 90 cents, or 10 cents for the amount of 25½ cents for each name, at* 81 *each.* Many farmers' clubs have, during the last year, joined together and obtained a considerable library through these premiums. N. B.—The books will be *delivered* to the recipients, (by mail or express, *free of all cost.*

No. 2—Family Clothes-Wringer.

This is a first-rate household implement—a great saver of garments, and a saver of hard work. Every woman knows that wringing by hand is not only the hardest, wrenching work of washing day, but that the twisting by hand-wringing breaks more of the shers of the garments than the washing and ordinary wear. With this machine set upon the edge of the wash-tub, the garments are easily and rapidly passed between two India-rubber rollers, the water falling back into the tub, and the garments dropping into a basket, in a drier condition than they can be wrung by hand, and therefore more quickly dried on the line. A child can do the work nearly as well as a full-grown clothes. The machine will save its cost several times in a year, simply in the saving of garments. We have had one of the first machines made in the country, and have used it nearly three years, and it is still as good as new. The machines now manufactured are still better, several improvements having been made. The machine figured, No. 2, is the best thing for family use. It is provided with cogs to move the rollers together, so that it is not possible to tear garments, as is the case with cheaper Wringers and provided with cogs. We present one of these No. 2 Wringers to any person procuring and forwarding 18 subscribers, at 81 each, or 37 at the lower club price, (90 cents each.)

Premium No. 3—Best Washing Machine.

Many ladies have asked us, for years past, to introduce a good Washing Machine among our Premium articles, but we have uniformly declined doing so, for want of the right kind of machine. We have, however, purchased a machine worthy of a place in the premium list, in which we mean to put none but those known to be first-rate articles. The **Nonpareil Washing Machine** we have had in constant use in our family for nearly a year past, and it has not only driven out half-a-dozen placed there on trial, but has really given excellent satisfaction. It is the only machine out of twenty we have tried, which the "help" cheerfully use without compulsion. It is a labor-saver and a clothes-saver—two important considerations. (See descriptive and advertisement on page 319.) The clothes are put in, in quantity, and quickly washed by simply turning a crank. The balance-wheel adjusts the force required, so as to make the turning easy. Take it all in all, it is the best Washing Machine we know of, and is worthy of a place in every family. They are of three sizes; we select No. 2, as the best size for common family use. The price of No. 2 is $14. This machine we will present (free by forwarding) 30 subscribers at the regular price, (81 each,) or 70 subscribers at the lowest club price, (80 cents.) The machine can be sent to any point in the land, or by express, and will be delivered free of all expense, except the freight after leaving the city

Premium No. 4—Sewing Machine.

90 Subscribers at 81 each, (or 130 at 80 cents each,) will entitle the person sending in the names to a first-rate **Lock Stitch Sewing Machine,** (including **Hemmer,**) new from the factory, and of the very best make. There is no better machine made than this made, as we have proved by nearly *five years'* use in our own family, in connection with other machines. We want no better. The fact that more of the Wheeler & Wilson machines are sold than of all others combined, is perhaps the best testimony in their favor. The terms on which it is offered above, will enable many families to secure one without direct outlay of money. The Premium Machines will be selected new at the manufactory, and will be forwarded, well boxed, with full directions for setting up and using, and with no expense, except for freight, after leaving the city.

Premium No. 5—Sewing Machine.

60 Subscribers at 81 each, (or 98 at 80 cents each,) will entitle the person procuring them to *Willcox & Gibbs'* $35 **Sewing Machine,** including a set of **Hemmers.** This is the best machine of its kind, (sewing with one thread,) and has several points superior to other machines. It is neat, well made, simple in its operation; and having tested one in our own family for more than two years, we think highly of it, and can recommend it to those who can not afford to buy the higher priced double-thread machines. Some of our neighbors think this machine ahead of all others. Premium 5 Will be selected and sent the same as No. 4.

Premium No. 6—Barometer.

10 Subscribers at 81 each, (or 44 at 80 cents each,) will entitle the person getting up the club to one of *Kendall's* **Anerold Barometers,** (Price $7 50.) This is a good, portable instrument, and valuable to every person as a weather guide, as well as for scientific purposes. We have had one in use for nearly three years, and find it not only accurate, but an admirable weather prophet. Scarcely a rain storm or gale of wind has occurred, that has not been foretold by our barometer. It will save to the farmer and others many times its cost, as a weather-indicator. These instruments resemble a large watch, 5 inches in diameter, and 2 inches thick. Each one is in a neat leather case, and when sent to a distance, this is packed in cotton, in a wooden box 4½ by 8 inches, and can go anywhere, by express or otherwise, with perfect safety.

Premium No. 7—The Aquarius.

This is a capital instrument, valuable to have in every house. It is a force and lift pump, which any one can catch up at a moment's warning, and throw from a pail or other vessel a steady stream of water upon a fire in a house, or elsewhere. It is also provided with both a jet-pipe for use, or sprinkler, and can be used for washing windows, carriages, &c., for sprinkling trees, plants, destroying insects, &c., &c. With it, it is easy to wash the second and third story windows, and to sprinkle water upon the roofs, while standing upon the ground. Such a supply of water often enable a person to so use a bucket or two of water as to extinguish a fire breaking out where it could not be reached with water from the pump alone. It is supplied with suction and injection India-rubber pipes, and with air-chambers to keep up a constant stream. The weight is 8 lbs., and it can be sent anywhere by express. Price, at our express. We estimate this for the Hydropult, as being cheaper, and quite as good. (Price $10.) We will present an **Aquarius** complete to any one forwarding a club of 23 subscribers at 81 each, (or 47 at 80 cents each.) N. B.—Further particulars can be obtained by sending for a descriptive circular to the manufacturers, W. & S. Douglas, Middletown, Conn.

Premium No. 8—Melodeon.

125 Subscribers at 81 each, (or 237 at 80 cents each,) will entitle the person getting up the club to one of *Geo. A. Prince & Co.'s* **$75 Melodeons** (6 octaves). These Melodeons are of very superior tone and finish. We have ourselves used one for three years past, and it has given the highest satisfaction, and is pronounced by all who have heard it, one of the very best. The different priced instruments are of equally good tone—the price varying with the size and style of finish. The size, prices, etc., of these instruments can be learned particularly by sending a stamp to Geo. A. Prince & Co., Buffalo, N. Y., for an illustrated descriptive catalogue. The instruments sent as Premiums will be sent new directly from the factory at Buffalo, ready boxed, and without expense to the recipient, except for freight. Schools and churches can readily combine in getting up and secure one of these instruments. This has been frequently done. See "N. B." under Premium No. 10.

Premium No. 9—Melodeon.

104 Subscribers at 81 each, (or 182 at 80 cents each) will entitle the person getting up the club to one of *Geo. A. Prince & Co.'s* **$60 Melodeons** (4½ octaves.) See No. 8

Premium No. 10—Melodeon.

90 Subscribers at 81 each, (or 130 at 80 cents each,) will entitle the person getting up the club to one of *Geo. A. Prince & Co.'s* **$40 Melodeons** (4 octaves.) Remarks above. N. B.—Higher or lower priced Melodeons will be given for larger lists, in the same proportion.

Premium No. 11—New Cyclopedia—A Splendid and Very Valuable Work.

96 Subscribers at 81 each, (or 140 at 80 cents each,) will entitle the person getting up the club to a set of *Appleton's* **New American Cyclopedia,** now in course of publication, consisting of *sixteen large volumes* of about 770 *pages each. This is a magnificent work, forming a whole library embracing every topic of human knowledge.* Fourteen volumes are now ready, and the remaining two will be furnished as soon as issued. We recommend it to every one, whether they procure it as a premium or not. The work is sold at $3 per volume, or $48 for the set. To no better purpose could any one devote the Winter evenings than in raising a club of subscribers to secure this for himself and family. Several schools have secured it, through the combined efforts of the scholars in raising clubs of subscribers. Boys have also secured it by their individual efforts.

Premium No. 12—Best Dictionary.

18 Subscribers at 81 each, (or 40 at 80 cts. each,) will entitle the person getting up the club to a copy of the *large Pictorial Unabridged Edition of* **Worcester's Dictionary,** (Price $7 50.) This now stands confessedly the most valuable Standard Dictionary published. It weighs nearly 10 lbs.; is 12 inches long, 10 inches wide, nearly 4 inches thick, and contains 1854 pages of 3 columns each, giving the spelling and pronunciation, with full explanations, of every word in the English Language, and as a source of general information on all subjects, stands next to the Cyclopedia. The Dictionary can be called for at our Office, or be sent by Express or otherwise, to any part of the country.

Premiums Nos. 13 to 18—Back Volumes—A First-rate Library.

These premiums (13 to 18,) will enable any one to secure the previous excellent volumes of the *American Agriculturist*

ist, as far back as Volume XVI. We have stereotype plates and can print any number desired of the English Volnmes, 16, 17, 18, 19, 20, and 21, and of the German Volumes 18, 19, 20, and 21. These will be sent in clean, new numbers, each volume by itself, with index complete, and be forwarded *post-paid*. The whole five can be taken together, or one or more copies of any particular volume be selected, as desired. They will be presented as in the table above, viz: For **20** Subscribers at $1 each, (or **36** at 80 cents each,) we will present **six volumes.** For **16** Subscribers at $1 each, (or **30** at 80 cents each,) we will present **five volumes.**——For **13** Subscribers at $1 each, (or **26** at 80 cents each,) **four volumes.**——For **10** Subscribers at $1 each, (or **20** at 80 cents each,) **three volumes.**——For **15** Subscribers at 80 cents each, **two volumes.**——For **10** Subscribers at 80 cents each, **one volume.**——Let every oue selecting these premiums be careful to name just *which* back volumes are desired.

Premium No. 19—Best File for Agriculturist.

Jacobs' Portfolio File, made just to fit the *Agriculturist*—the name gilded on. This is a leather cover or portfolio, so arranged that successive numbers of the paper can be inserted in a minute, and be properly preserved in book form for reading. When one volume is completed, the sheets can be removed and stitched, and a new volume inserted. A single cover will answer for a dozen successive volumes. It is the most complete file yet made. The price is $1, and the postage 23 cents. We will forward it, post-paid, to any one sending *eleven* subscribers, at the lowest club price, (80 cents each.)

Premium No. 20—Paints.

20 Subscribers at 80 cents each, will entitle the person getting up the club to an assortment of *Windsor & Newton's* **Water Color Paints**—consisting of 12 colors, put up in a neat mahogany case, with brushes, etc. These Paints are imported from London, and are by all considered the best in the world. They are adapted to the finest work, or they will make a neat and appropriate present to any of our younger readers. They will be sent post-paid any where in the United States within 3000 miles.

Premium No. 21—Paints.

15 Subscribers at 80 cents each, will entitle the person getting up the club to an Assortment of *Osborne & Hodgkinson's* **Water Color Paints,** consisting of 24 colors or shades, put up in a neat case with brushes, cups, etc. These are of American manufacture, and though not so fine as the above, will answer for ordinary practice by children or beginners, and for common sketching. Sent same as No. 20.

Premiums Nos. 22 to 26.

We have not space left to describe these particularly, this month. The Cylinder Plow was described in this journal last year. It is undoubtedly a great improvement. The Eagle Plow is well known, and so is the Hay and Straw Cutter, and the Steel-toothed Cultivator, one of the most useful implements on the farm. The Lard and Wine Press is a very convenient household implement, for pressing out lard or tallow, the juice of grapes, currants, berries, &c. For the prices, and subscribers required, see the table above.

Market Review, Prices, etc.

American Agriculturist Office, New-York, Saturday, Oct. 18, 1862.

The movements in Breadstuffs continue on a very heavy scale, surpassing in magnitude even those of the corresponding periods of last year; and at present no well-informed dealer anticipates any serious falling off in the proportionate volume of business. The extraordinary rise in the price of gold and the corresponding advance in Sterling Exchange have served materially to encourage the export trade; and the Custom House returns snow a very satisfactory result in this most important branch of the commerce of the port. Our table of prices below indicates a *large advance* in the market value of all kinds of Breadstuffs. This is of course largely due to the rapid increase in the value of gold, as compared with the paper currency, used in the purchase of produce in this market, as well *as throughout the country*. An illustration may be interesting: When a gold dollar is selling for $1.35 of the currency in use, as it was on the 15th inst, the currency dollar is really worth only a fraction over 74 cts. in gold. A barrel of flour, selling for $7 in currency, therefore brings only $5.18 in gold. On the 18th of September (when our last report was made up) a gold dollar was worth $1.17 in currency, making the value of the currency dollar (accepting gold as the standard) about 85½ cts. The currency dollar has since depreciated 11½ cts., or gold has advanced in that proportion. The highest shipping grade of extra State flour sold on the 18th of September for $5.70, and to-day for $7, showing a nominal rise of $1.30 per bbl. Allowing, however, for the advance in gold, there is still an actual specie rise in the price of extra State flour of about 50 cts. per bbl., which is a decidedly encouraging improvement. This illustration applies to the whole list of articles of Produce....In every branch of the Produce trade, the activity has been quite unusual. The home and export demand has been brisk, especially for Breadstuffs and Provisions, and speculation has also set in, partly encouraged by the abundance of currency. As we close the present review gold is reported as declining in price, and paper currency is rising in value, which explains the cause of the temporary heaviness in the markets, to-day. Another adverse influence is that which results from the ravages on our Atlantic commerce, by the rebel Steamer "290," now known as the Alabama. Shippers are reluctant to send forward their property, until they can feel assured of its safe transportation to European markets. Foreign vessels can carry freight securely, but the number of these in port is not equal to the requirements of the export trade, and the high rates which their owners are asking operate as a hindrance to free shipments. It is to be sincerely hoped that our Navy will soon dispose of this piratical craft and any others which *professedly* neutral England may permit to be fitted out from her ports.

The following tables, made up from a great number of figures, present in brief space, and in convenient form for reference and comparison, the most comprehensive view of the transactions in the breadstuff markets to be found in any journal. They are prepared specially for the *American Agriculturist* by a careful reporter of long experience, who devotes his entire time to the special business of watching the markets.

N. Y. Live Stock Markets.—THE CATTLE MARKETS have been well supplied for a month past, the receipts averaging 5,154 head per week. (For two months the weekly average has been 5,252, a larger number than were ever previously received in the same length of time.) There was no change in prices the first two weeks, and the slight advance of the week following was met by a similar decline at the last market, so that prices are the same as at our last report. The cattle were about all sold each week. Until this week much of the stock was poor, but at the last general sales, Oct. 14th, with a good run of well fed cattle in the yards, the prices were equivalent to 8½c. to 9c. per lb. for the estimated dressed weight, for first quality; 8c. for fair beeves, and 5½c.@7c. for very poor to medium animals, the average of all kinds being 7½c.

Veal Calves.—Receipts are on the increase, and prices are advancing, with a brisk demand for good fat veals which readily command 6c. per lb. live weight. Common calves 5c.@5½c.

Sheep and Lambs.—The sheep trade has been remarkably good during the past month, affected considerably by the advance in wool which caused a corresponding rise in pelts. Skins are now worth $1.37 to $1.40 in lots. A good drove of 100 lb. sheep will bring 5c. per lb. live weight, and a little more if extra fat. Ordinary sheep are worth 4¼c.@4½c., and lambs are selling at 5c.@6c. Sold in mixed lots of sheep and lambs, they bring about $4 per head. Some fat lambs have been sold at $5¼ each. Receipts have averaged 13,174 per week.

Live Hogs.—The Autumn season, with cool weather for packing, always brings an abundance of hogs. The average receipts for the past month have been 24,000 per week. Prices have remained nearly stationary, with a good demand at 4⅛c.@4½c. per lb. live weight, for prime heavy corn-fed hogs, yielding good hams and lard. Poor, thin hogs abound, and go off slowly at 3c.@3½c.

The Weather has been mild for Autumn, with scarcely a touch of frost in this vicinity. Everything has been very favorable for maturing and harvesting late crops.——OUR DAILY NOTES, condensed, read: *September* 20, clear, warm A. M. cloudy P. M.—21, cloudy A. M. clear P. M.—22, 23, clear, fine, mild—24, cool and cloudy—25, 26, 27, clear, fine—28, cloudy—29, clear—30, cloudy, ground dry, having had very *little* rain for three weeks.—*October* 1, 2, 3, Northeast rain storm, clearing off warm on afternoon of 3d—4, clear, warm, with rain at night—5, 6, clear, cool—7, 8, 9—fine, warm days—10, N. E. rain storm—11, rain A. M., cooler P. M., with light showers—12, cloudy, rain at night—13, continued rain—14, cloudy A. M., clear and warm P. M.—15, clear and moderately cool—16, cloudy A. M., light rain P. M., with heavy shower at night—17, 18, clear fine, bright days.

The Rain Fall from Sept. 15th to Oct. 15th, amounts to 3.34 inches, which is light for this season of the year. The Barometer has ranged from 29.75 inches to 30.20 inches—a light variation.

Thermometer at 6 A. M., New-York.

[Observations carefully made upon a standard Thermometer (Fahrenheit.)—*r* indicates rain—*s*, snow.]

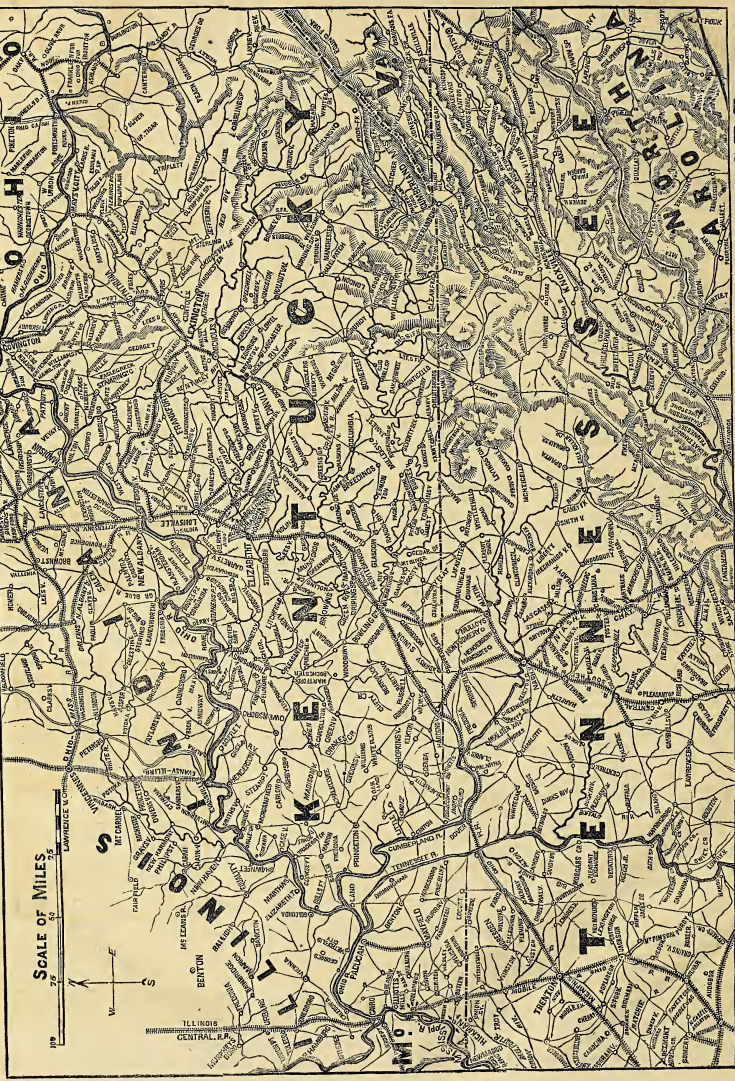
INDUSTRIAL EXPOSITION, PARIS, 1861.

Office No. 505 Broadway, New-York.

STAMMERING.

PAMPHLETS (of the *new edition*) describing BATE'S APPLIANCES, the new *Scientific* and only known means for the rapid and permanent CURE OF STAMMERING, are now ready, and can be obtained, free of expense, by addressing H. C. L. MEARS, No. 82 Broadway, N.Y



MAP OF KENTUCKY AND PART OF TENNESSEE.

The above Map (engraved expressly for the American Agriculturist) shows the field of the operations of the armies in Kentucky and Tennessee.

Death of a Prominent Pomologist.

The country will be pained to learn of the decease of that well-known horticulturist and nurseryman, Wm. Reid, of Elizabeth, N. J., on the 8th of October, of an affection of the heart. His death was announced at the Fruit Growers' Meeting at the office of the *American Agriculturist*, Oct. 9th. where many gentlemen present testified to his worth as an individual, as a public man, and especially to his eminent position as one of the best pomologists, and horticulturists of the age. A vote of condolence and sympathy with the family was passed and transmitted to the family by the Secretary.

Pumpkins, Squashes, and Ornamental Gourds.

There will be a **Public Exhibition** of PUMPKINS, SQUASHES, AND ORNAMENTAL GOURDS, at the office of the *American Agriculturist*, 41 Park Row, New York City, opening on Wednesday, **Nov. 5th, 1862,** at which the following prizes will be paid by the Publisher, upon the official award of competent Committees.

CASH PREMIUMS.

No. 1—For the *Heaviest* Pumpkin or Squash		$20.00
No. 2—For the 2nd	do.	10.00
No. 3—For the 3d	do.	5.00
No. 4—For the Best	do. do. for cooking.	10.00
No. 5—For the 2nd Best	do. do. do.	5.00
No. 6—For the largest yield on a single Vine...*		10.00
No. 7—For the 2nd	do. do. *	5.00
No. 8—For the largest and finest collection of Fancy or Ornamental Gourds*...		10.00
No. 9—For the 2nd	do do. *....	5.00

* All to be grown by one person and to be accompanied by an affirmed statement from the grower, and two disinterested persons who assist in gathering the specimens.

Note 1.—The specimens receiving the Prizes will remain on Public Exhibition at the pleasure of the Publisher who offers the prizes. The other specimens will be subject to the order of the exhibitors, or they will be sold at Auction or otherwise disposed of, for their benefit.

Note 2.—All Exhibitors must notify us of their intentions by Oct. 10th, and deliver specimens for competition on or before Nov. 3d. Specimens to be delivered free of charge.

Where Do You Live?—If every one writing to this office, on any topic whatever, would make it a point to always give the Post-Office, *County*, and **State,** a great deal of trouble, vexation, and some hard feelings, would be saved. We very often receive letters requiring answers, which are necessarily thrown aside simply because the name, or the Post-Office, or the State, Is omitted; sometimes all three are lacking. We of course get blamed for inattention, oversight, haughtiness, and all that, which may be obviated by a little care.

American Agriculturist.

For the Farm, Garden, and Household.

A THOROUGH-GOING, RELIABLE, and PRACTICAL Journal, devoted to the different departments of SOIL CULTURE—such as growing FIELD CROPS; ORCHARD and GARDEN FRUITS; GARDEN VEGETABLES and FLOWERS; TREES, PLANTS, and FLOWERS for the LAWN or YARD; care of DOMESTIC ANIMALS, &c., &c., and to HOUSEHOLD LABORS. It has also an interesting and instructive department for CHILDREN and YOUTH, alone worth the cost of the paper.

A full CALENDAR OF OPERATIONS every month.

THREE to FOUR HUNDRED, or more, illustrative ENGRAVINGS appear in each volume.

Over TWELVE HUNDRED PLAIN, PRACTICAL, instructive articles and useful items, are given every year.

The Editors and Contributors are all PRACTICAL WORKING MEN.

The teachings of the AGRICULTURIST *are confined to no State or Territory, but are adapted to the wants of all sections of the country—it is, as its name indicates, for the whole* AMERICAN CONTINENT.

TERMS—INVARIABLY IN ADVANCE,
(For either the English or German Edition.)

One copy, one year	$1 00
Six copies, one year	5 00
Ten or more copies one year	80 cents each.

☞ Add to the above rates: Postage to Canada, 6 cents; to England and France, 24 cents; to Germany, 36 cents.

Postage anywhere in the United States and Territories must be paid by the subscriber, and is *only six cents a year*, if paid in advance at the office where received.

All business and other communications should be addressed to the Editor and Proprietor,

ORANGE JUDD, 41 Park-Row, NewYork City.

FROM THE STEAM PRESSES OF JOHN A. GRAY.

American Agriculturist in German.

The AMERICAN AGRICULTURIST is published in both the English and German Languages. Both Editions are of the same size, and contain, as nearly as possible, the same Articles and Illustrations. The German Edition is furnished at the same rates as the English, singly or in clubs. A club may be part English, and part German.

Bound Volumes—Binding—Covers.

We have complete sets of Vols. 16, 17, 18, 19, and 20, both unbound, and bound separately in neat covers with gilt lettered backs.

PRICES AT THE OFFICE.

Volumes 16, 17, 18, 19, and 20, *unbound*.....$1.00 each.
Volumes 16, 17, 18, 19, and 20, *bound*.....$1.50 each.

PRICES WHEN SENT POST-PAID BY MAIL.
(*They can not go unpaid.*)

Volumes 16, 17, 18, 19, or 20, *bound*.....$2.00 each.

BINDING.—Sets of numbers brought to the office will be bound up neatly (in our regular style of binding the *Agriculturist*) for 50 cents a volume.

PREPARED COVERS.—Covers for binding, neatly made, with title, etc., gilt upon the back, ready for the insertion of the sheets by any bookbinder, can be furnished for Vols.12, to 20 inclusive, at 25 cents per cover. *Covers can not go by mail.*

TO ADVERTISERS.

Circulation of the Agriculturist.

Beyond all doubt or controversy, the circulation of the American Agriculturist to regular subscribers, is many thousands greater than that of any other Agricultural or Horticultural Journal in the World, no matter what its character, or time or place of issue. The publisher is ready at all times to substantiate this statement by comparing books.

Advertisements.

Advertisements to be sure of insertion must be received at latest by the 15th of the preceding month.

TERMS—(invariably cash before insertion):

FOR THE REGULAR EDITION ONLY.

Fifty cents per line of *space* for each insertion.
One whole column (125 lines), or more, $60 per column.
☞ Business Notices, *Eighty cents* per line of space.

FOR THE GERMAN EDITION ONLY.

Ten cents per line of *space* for each insertion.
One whole column (130 lines), or more, $19 per column.
☞ Business Notices, *twenty* cents a line.

WANTED BY A YOUNG MAN RECENTLY from Pennsylvania Agricultural School, a situation to work in a Nursery and Greenhouse. Address R. O. DWIGHT, Box 2631, New-York P. O.

A FARM WANTED, convenient to railroad, with good buildings, &c., from one to two hundred acres, address, stating price, terms, situation, &c., H. OSBORNE, Box 3559, New-York P. O.

A DESIRABLE COUNTRY RESIDENCE NEAR NEW-YORK FOR SALE.—Containing a large Dwelling, surrounded with trees, shrubbery, lawn, etc. An excellent Barn, with work shop and store rooms. A large garden, (1¼ acres,) thoroughly prepared, and supplied with fruit trees, grapes, etc. With the above, and adjoining it, is another fine plot of about 4 acres, admirably adapted for building upon, or for cutting up into smaller building lots. The two will be sold together or separately. No care or expense has been spared in fitting up the above place, and it is ready for occupation by any citizen who may not wish the trouble of preparing a home. The location is convenient to churches and good schools, and every way desirable. Accessible from the city in 30 minutes, nearly every hour during the day. About $6,000 or $7,000 cash will be required; the rest can remain on mortgage if desired. For further particulars address Z. Box 189, N. Y. Times office.

GOOD MEN WANTED in all parts of the COUNTRY, To sell KETTELL'S Illustrated

HISTORY OF THE GREAT REBELLION, Sold only by Canvassing Agents. Exclusive Territory given. Vol. I. now ready for delivery.
The work is printed both in ENGLISH and GERMAN, and is the BOOK that THE PEOPLE DEMAND.
For territory and terms apply to
N. C. MILLER, No. 25 Park-row, New-York.

ONION CULTURE—Third (new) Edition. This work comprises in 32 pages all the particulars for successful Onion Culture, from Selection of Seed to Marketing the Crop—being the practical directions given by *seventeen experienced* Onion Growers, residing in different parts of the country. Price 21 cents (or 7 stamps), sent post-paid. Address Publisher of *Agriculturist*.

Manufacturers of Pumps, Hydraulic Rams, and other Hydraulic Machines, Hardware, &c., &c., Middletown, Conn. Branch Warehouse, 87 John-st., New-York, where the AQUARIUS can be seen, with Samples of all our Goods.

See Premium No. 7, American Agriculturist.

For Sale by H. B. LANE, 42 Park Row, New-York.

ADAMS'
COTTAGE
Printing Press.

PORTABLE PRINTING OFFICES

For the use of Druggists, Merchants, Seedsmen, and others.
Prices $25, $40, and $60.
For sale by the ADAMS PRESS COMPANY, 31 Park Row New-York.

These convenient Portfolio Paper Files are for sale at the office of the *American Agriculturist*. They are of various sizes, from the large folio to small octavo.

Those made expressly for the *Agriculturist* are worth 60c., 75c. and $1, according to quality, to which 25 cents must be added if to be sent by mail.

EVERY LADY, MOTHER, MILLINER, AND Dressmaker should subscribe for Mme. DEMOREST'S MIRROR OF FASHIONS. It is sent regularly as soon as issued; and the new and desirable full-sized patterns alone are worth many times times the cost of the magazine, independent of the valuable premium that is offered.

The Adirondac Grape.

The earliest and best American Grape known, ripening two weeks earlier than any other good grape. Possessing the most delicious flavor, in fact, equal to the most delicate hot-house grape. It originated at the base of the Adirondac range of mountains on the shore of Lake Champlain. It is believed to possess all the requisites to establish its character as the EARLIEST AND BEST NATIVE GRAPE.

PRICE. One year old vines $3. A limited number of two year old vines at $5. All cut back to 3 or 4 eyes.

Vines will be carefully packed, and forwarded by Express or otherwise. Small packages (less than a pound) can be sent by mail, at one cent per ounce, to any part of the United States. Address with remittance

OUR "EXCELSIOR
BURR STONE MILLS,"
AND
ANTI-FRICTION
HORSE POWERS.

Have taken the HIGHEST PREMIUMS WHEREVER EXHIBITED! NINE FIRST PREMIUMS being received from WESTERN STATE FAIRS last year.

THE MILL may be driven by *horse, water,* or *steam power,* does the work equally as well as the best flat stone mills in milling establishments, and requires but *one-half the power* to do the same amount of work. They are made in the best manner, and will last *thirty years,* and *cost nothing for Repairs.*

THE HORSE-POWER runs upon iron balls, and requires but TWO AND A HALF POUNDS DRAUGHT to keep it in motion. With the same number of horses it will do TWENTY-FIVE PER CENT more work than ANY OTHER POWER IN USE.

Price of Power for 1, 2, 3, or 4 horses.....$125
Price of Power for 5 to 8 horses.....175

THE $125 POWER WILL DRIVE ANY THRESHING MACHINE, and was awarded the first premiums OVER THE BEST 8 AND 10 HORSE POWERS at the State Fairs last Fall.

☞ EVERY MACHINE IS GUARANTEED TO GIVE SATISFACTION, OR THE MONEY WILL BE REFUNDED. ☜

$150. BEST PIANOS. $150.

J. P. HALE & CO, having removed to their new ware rooms

No. 478 BROADWAY,

are now prepared to offer the public a magnificent NEW SCALE, full

7 OCTAVE

ROSEWOOD PIANO,

containing all improvements known in this country or Europe. Over Strung Bass, French Grand Action, Harp pedal, Full Iron Frame, for

$150 CASH.

Warranted for Five Years.

Rich moulding cases

$175 TO $200.

All warranted made of the best seasoned material, and to stand better than any sold for $400 or $500, by the old methods of manufacture. We invite the best judges to examine and try these new Instruments, and we stand ready at all times to test them with any others manufactured in this country.

J. P. HALE & CO.,
473 Broadway, New-York.

GROVER & BAKER'S

CELEBRATED NOISELESS

SEWING MACHINES.

Acknowledged to be Superior to all Others.

495 *BROADWAY, NEW-YORK.*

"Grover & Baker's is the best."—*Am. Agriculturist.*

FOR SEWING MACHINES.

JONAS BROOK & BROTHERS'

PRIZE MEDAL SPOOL COTTON,

WHITE, BLACK, AND COLORED.

200 or 250 yard spools.

For MACHINES, use BROOK'S PATENT GLACE for upper thread, and BROOK'S SIX CORD RED TICKET for under thread. Sold by all first class dealers in city and country; also in cases of 100 dozen each, assorted numbers, by WM. HENRY SMITH, Sole Agent, 59 Vesey-st., New-York.

AN IMPROVED CLOTHES WRINGER.

The best now in use.

Agents wanted for different States and Counties. Manufactured and for sale, wholesale and retail, by

HAINES & PELL, 97 Cortlandt-st., New-York.

Pyle's O. K. Soap

takes the HIGHEST PREMIUMS. The Agricultural Societies of New York, New-Jersey, and Queens Co., L. I., at their recent exhibitions granted the HIGHEST PREMIUMS to **James Pyle** for Soap and Saleratus. Housekeepers will find it much to their interest to use these articles. Sold by Grocers generally. JAMES PYLE, Manufacturer,
30 Washington Corner of Franklin-street, New-York.

Sectional View. A, Lens; B, Object glass; C, Diaphragm; D, Object for Three Dollars. Address

HENRY CRAIG,
182 Centre-st., New-York.

THE CRAIG MICROSCOPE.

This is the best and cheapest microscope in the world for general use. It has just received the First Premium—Silver Medal —at the Ohio State Agricultural Fair. It requires no focal adjustment, magnifies about 100 diameters, or 10,000 times, and is so simple that a child can use it. It will be sent by mail, postage paid, on the receipt of $2.25, or with six beautiful mounted objects for Three Dollars. Address as above.

TEETH

UPON ALLEN'S SYSTEM

CAN BE OBTAINED AT

22 Bond-st., New-York.

By this method the TEETH, GUMS, ROOF, and RUGÆ of the MOUTH are all truthfully represented, affecting those delicate tints, shades, and forms peculiar to the natural organs, thus concealing from the observer the human agency in forming them. This we do positively accomplish, as evinced by our numerous patrons. The natural expression of the mouth, and original contour of the face can also be restored, which rejuvenates the waning cheek.

A descriptive pamphlet may be obtained by addressing DRS. J. ALLEN & SON, as above.

Hickok's Patent Portable KEYSTONE CIDER AND WINE MILLS.

WINE PRESSES, CIDER MILL SCREWS, FRUIT GATHERERS, TURN TABLE and other APPLE PARERS, &c.

Sold at wholesale and retail by

R. H. ALLEN & CO.,
189 and 191 Water-st., New-York.

MRS. WINSLOW,

AN EXPERIENCED NURSE and Female Physician, presents to the attention of Mothers her

SOOTHING SYRUP

FOR

CHILDREN,

which greatly facilitates the process of Teething, by softening the Gums, reducing all Inflammation—will allay ALL PAIN and spasmodic action, and is

Sure to Regulate the Bowels.

Depend upon it, mothers, it will give rest to yourselves, and

Relief and Health to your Infants.

It not only relieves the child from pain, but invigorates the stomach and bowels, corrects acidity, and gives tone and energy to the whole system. It will almost instantly relieve

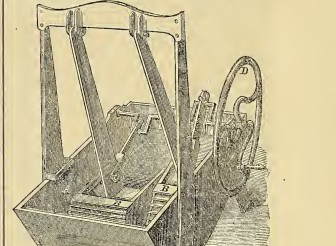
Griping in the Bowels and Wind Colic,

and overcome Convulsions, which, if not specially remedied, end in death. We believe it the BEST and SUREST REMEDY IN THE WORLD, in all cases of DYSENTERY and DIARRHŒA in children, whether it arises from Teething or from any other cause. We would say to every mother who has a child suffering from any of the foregoing complaints—DO NOT LET YOUR PREJUDICE, NOR THE PREJUDICES OF OTHERS, stand between you and your suffering child and the relief that will be SURE—yes, ABSOLUTELY SURE—to follow the use of this medicine, if timely used. Full directions for using will accompany each bottle. None genuine unless the fac-simile of CURTIS & PERKINS, New-York, is on the outside wrapper.

Sold by Druggists throughout the world.

Principal Office, 13 Cedar-Street, New-York.

Price only 25 cents per bottle.



The NONPAREIL WASHING MACHINE

Has been in operation since April, 1861, and the severe and varied tests, to which it has been subjected, in country and city families and laundries, demonstrate that two-thirds the labor and time, and half the soap required in hand washing, are saved by its use, and no injury can possibly result to the most delicate fabric from its action. It is a squeezing machine, and it washes with equal effectiveness a cambric handkerchief, or a bed quilt.

The machine is carefully made of the best materials, and its strength and durability will be found in keeping with its extreme simplicity. There is nothing in its construction liable to get out of order; and no training is required to enable the least skillful person to work it satisfactorily. A girl twelve years old can operate it.

Three sizes of family machines are made, their capacity being about the bulk of five, eight, and twelve shirts respectively. Prices: No. 1, $10; No. 2, $14; No. 3, $17.

Machines to go by Power are manufactured for use of Hotels and Laundries.

Circulars, giving full descriptions, will be forwarded by

OAKLEY & KEATING 13 South-st., New-York.

Only one Item in these Columns to be Read—Which is it?

3,300 Copies Free.

The offer of 14 months for the price of 12, extended only to October 31st. But we print 3,300 extra copies of this November number, of which 300 will be reserved for new subscribers from the Pacific Coast, Utah, and other distant points, and the rest will be presented to the first 3,000 new subscribers now received for volume 23, (1863). All new names for a year, now coming in, are at once entered from the date of reception until the close of 1863. Thus then, all new subscribers sent in this month, get 13 months at the price of a year, and the first 3,000 will receive 14 months. This applies to *all new* subscribers, whether coming singly, or in premium clubs, or for maps, or as awards from Agricultural Societies, or otherwise.

Good Maps Still Offered.

Our arrangement for *Premium Maps* was but temporary, and they could not be promised far ahead. We are happy to state, that they can be continued during November. Here is the offer: For one new subscriber at $1 a year, sent now or during November, we will present, when desired, a large colored map of *Virginia*, including Maryland and part of Pennsylvania. This covers more than *ten square feet*, and gives all the rivers, small streams, mountains, cities, villages, and principal roads in the whole state of Virginia, so completely that the location and every movement of the armies can be followed.

Or,

Instead of the above, a large map of *all* the Southern States, giving all the principal towns, rivers, streams, etc., etc. The above maps are designed as premiums for *new* Subscribers. Any present Subscriber sending in one or more new names, receives a map for each; he may also receive a copy of it for his own subscription, and for other old subscriptions, if they are renewed at the same time at $1 a year. These Maps are wanted by everybody just now.

Another Good Map.

For *two* new subscribers at $1 each we will this month send, when desired, one of the best maps published of the whole *United States*, including also the Canadas and New Brunswick. This covers nearly 1½ square feet. Every county in all this broad territory is colored separately. Mr. Lloyd, the publisher, says there are 300,000 names engraved on it. We could not count them all.

How to Pay Taxes Easily.

A farmer in Central New-York, writes to the *American Agriculturist:* "I paid my taxes last year by investing a single dollar in this wise. After long solicitation by a neighbor, I subscribed for your journal, as it happened, just before you published the article advising us that grain would be higher. I was on the point of selling, but after reading your remarks decided to wait, and thereby gained over seventy dollars on my crop—enough to pay my taxes for two years." This is one instance of many that have come to our knowledge, where a single suggestion in this journal has returned many fold the price of subscription. Help your neighbor pay his taxes next year by inducing him to read and profit by the valuable information continually published in these columns. He will thank you.

In Good Company.

The constant readers of the *Agriculturist* number far more than one hundred thousand, largely made up of the most intelligent, enterprising members of the agricultural community. It is worth something to be introduced to such a society, and share the benefits of their thoughts and suggestions. These are freely presented in this journal, and it would be strange, indeed, if among the whole amount of information afforded, there could not be gleaned a single dollar's worth of useful material for thought and practice. A large number of the subscribers have assured us that they would not part with the knowledge thus gained for many dollars. Please invite your friends and your neighbors to join this good company.

To-day as well as To-morrow.

Those who feel disposed to try for one of our premiums (see page 346) can do it to-day as well as next week, and even better, for subscribers sent in now get not only all of volume 22, (1863) but the rest of this year thrown in.

A Thinking Machine,

Would be worth more to the community than any invention yet brought out. A good journal is the nearest approach to it. It presents thoughts to men, which would never have entered their heads but for its aid, and thus it answers the purpose of a thinking machine. Consider a moment, that hundreds of contributors in every part of the country send their best practical thoughts on farm, garden, and household matters, to the *American Agriculturist*, which works them up, and presents the whole to subscribers for a single dollar a year—and for less to Clubs. Can money be better invested? Please ask your neighbor what he thinks, and will *do* about it.

"Two of a Trade Can Agree,"

Notwithstanding the old adage that they *can't*. Here is a proof in point: Over *Six Hundred* cotemporary Journals have this year stated editorially that the *American Agriculturist* is the best journal in the country for the Farm, Garden, and Household. Most of these journals are on file and can be shown.—"What everybody says must be true." We can not tell how many subscribers think or say the same things, and speak from personal experience. The Publisher will, of course, be pleased to have a hundred thousand more read the paper so as to be able to speak from a fortunate experience. Will the reader please ask his neighbor to make up one of the hundred thousand? There are many, etc., offered to those who obtain subscribers, and extra copies to the new comers.

Good all Around.

Is there a widow or a soldier's wife in any neighborhood, to whom her neighbors would like to give a "benefit?" What better than a labor-saving Sewing Machine? Here is a plan to get one easily. Let *ten* of her neighbors (the ladies of course) unite their efforts for a day, and each solicit 9 subscribers for the *Agriculturist* at $1 a year; or 13 subscribers at the lowest club price of 80 cents each. This will secure a first-rate Wheeler & Wilson machine (see premium list p. 346). By going to different parts of the town a club can be readily raised. Almost every one will put down a dollar for such an object, especially when he will at the same time secure the *Agriculturist* for a whole year, or 14 months if it be done soon. The enterprise will pay all around. At least one will be greatly benefited, and 90 to 130 copies of the paper in a neighborhood or town will tend to rural improvements, to say nothing of increased products upon the farms and gardens, and in-door improvements as well.

How to Buy Cheap.

On page 346 are named a lot of really good articles, one or more of which is wanted by almost everybody. We *give* these articles in return for lists of subscribers—a cheap way to *buy* them. The list gatherer loses no money if he does not gain the largest premium aimed for. Between three and four *thousand* persons have secured one or more of these premiums during the past two years. "What man (or woman or child) has done, man (or woman or child) can do." Who will have a Premium?

Did You Read,

On page 309, what a Michigan farmer said? How a single hint in his *Agriculturist*, about sowing his wheat crop, gave him $300 *clean profit!* Such hints are scattered all along through every number. A man should read without thinking, and the more thinking he does, the better will the work of his hands pay. Please mention the matter to those neighbors who have not yet learned that it *pays* to read and think earnestly about their own business.

Our General.

The *American Agriculturist*, though not a military journal, has yet supplied one general for the field whose services can not be over estimated, namely: "GENERAL INFORMATION"—in all that pertains to operations on the farm, garden, and household. From the *Agriculturist* arsenal there are annually sent forth to the army in the *field*, over 2,000 loads of "fixed ammunition" in the form of useful items, all prepared with especial reference to the wants of the army combating with ignorance, poor crops, poor housekeeping, etc., etc. These articles are *not* mere rehashes of selections from irresponsible sources, but are prepared by our own editors and contributors. Is there not work for our *General* in your neighborhood? Please aid in introducing him into every "strong-hold."

☞ For Terms, etc., See Page 349.

AMERICAN AGRICULTURIST,

FOR THE

Farm, Garden, and Household.

"AGRICULTURE IS THE MOST HEALTHFUL, MOST USEFUL, AND MOST NOBLE EMPLOYMENT OF MAN."—WASHINGTON.

ORANGE JUDD, A.M., EDITOR AND PROPRIETOR. Office, 41 Park Row, (Times Buildings.)

ESTABLISHED IN 1842. Published both in English and German.

$1.00 PER ANNUM, IN ADVANCE. SINGLE NUMBER, 10 CENTS. For Contents, Terms, etc., see page 378.

VOLUME XXI—No. 12. NEW-YORK, DECEMBER, 1862. NEW SERIES—No. 191.

Entered according to act of Congress in the year 1862, by ORANGE JUDD, in the Clerk's Office of the District Court of the United States for the Southern District of New-York.

☞ Other Journals are invited to copy desirable articles freely, if each article be credited to *American Agriculturist.*

☞ See pages 358, 375 and 378, this month.

December.

"All nature feels the renovating force
Of Winter; only to the thoughtless eye
Is ruin seen. The frost-concocted glebe
Draws in abundant vegetable soil,
And gathers vigor for the coming year.
A stronger glow sits on the lively cheek
Of ruddy fire, and luculent along
The purer rivers flow, their sullen deeps
Transparent, open to the shepherd's gaze,
And murmur hoarser, at the fixing frost."

Rude Winter is upon us, with all his frosts and storms. A complete change has come over the aspects of the earth and sky, and a change almost as great over our feelings. The earth has changed her drapery of green for one of russet brown or of snowy whiteness. The sky has lost its golden hues, and the sun, even when it tries to shine, has a feeble smile. The gorgeous colors of the forests lasted but for a day, and now the Winter winds whistle through the desolate branches. The running streams are bridged with ice, and the merry skater on wings of steel rushes along where floating keel plowed its way.

This complete change of the aspects of nature and of the occupations of man, is one of the charms of country life, and one of the advantages which the farmer has over the dwellers in town. The citizen is very much tied up to the same routine in business or in pleasure the year round. He threads the same streets, jogs on over the same horse railroad or in the same omnibus, mounts to the same chair at his office desk, reads by the same gas light the year round. If he packs up his valise, and his wife and daughters get their big trunks ready for a trip to the country, when the dog star is in the ascendant, he does not necessarily have a change or experience any new sensations. The big trunks export no inconsiderable part of the city to Saratoga or Newport, and he finds about the same people and the same pleasures in his Summer jaunt, as in his abode in the city for the rest of the year. If he eats boiled salmon and drinks champagne at the watering place, did he not do the same at home? If he ventures on a glass of Congress water at the Springs, when his stomach is a little out of order, did he not drink the same in Winter whenever the doctor ordered it? If he ventures on bathing, did he not have the same at home, with plenty of soap and crash towels? If the young ladies dance and flirt in the Summer vacation, did they do anything else in the Winter? If the good mother has a reasonable solicitude about marriage prospects amid the gayeties of the grand ball that winds up the season, does she not have a similar palpitation when the season opens for the Winter in the city?

But the dwellers upon the farm are forced by their occupation, and by their circumstances, to a great variety of employment. Every season and almost every month brings new scenes, suggests new thoughts, and affords new enjoyments. If he travel over the same beaten track to mill and to meeting, the scenes along the way are constantly changing. Every month brings its variety of flowers, and its new shade of green upon the meadow, and upon the forest, until the grass becomes russet and the foliage blushes with every shade of crimson, and dies in a blaze of glory. Even the leafless forest has its charms, and the spray of many of our forest trees, as we look up at them against the grey Winter sky, is hardly less beautiful than in Summer. We now have a chance to see beauties in the frame work of the tree, in the arrangement of the branches, and the smallest twigs that the drapery of Summer conceals from us.

Even this season has its attractions for the eye, and for the ear, as well as for the heart. The flowers have gone and every green thing has withered, but the cunning handiwork of the Great Architect is everywhere manifest. We see it in the delicate frost work on every fence and building, and along the banks of every stream. What can be more charming than the fresh fallen snow on a bright Winter morning, as it lies sparkling in the sun, or hangs upon the loaded bushes by the roadside—mimic leaves and fruits, the creations of the night. Then Summer with all its glories has no more brilliant sight than the forest or orchard after a freezing rain, every limb sheeted with ice and every twig pendant with its burden of jewels. The ice that spans the lake and river, is hardly less beautiful than the unfrozen water. We see a new world as we look down into the transparent depths beneath—fishes at rest in their Winter quarters, and shells and aquatic plants.

The songs have indeed gone from the forest, and we only hear now occasionally the solitary call of the bluejay, the cawing of the crow, or the sharp rattle of the woodpecker foraging for worms along the dead branches. But still, there is music even in Winter. Every one accustomed to observe the phases of nature, has noticed the different sounds of the breeze sweeping through leafless trees and through the Summer forest. Almost every kind of tree has a note peculiar to itself, both in full foliage and when its branches are bare. The evergreens alone give forth the same soothing murmur in Summer and Winter. These are the connecting link between the dead past and the bright future, showing that God has not forgotten the earth amid the wreck and ruin of Winter. Who has not noticed the sonorous ring of the loaded cart or sled, as it is driven over the crisp snow path? Then we have the song of the woodman and the echoes of his ax, and the crash and thunder of the trees as they are laid low. Once, too, one of the pleasant sounds of this season was the thud of the threshers as they wielded the flail upon the barn floor. But the improved threshing machines have nearly ended that—saving days and weeks of time to be devoted to other pursuits profitable to the purse or the mind.

Winter brings a very pleasant change of occupation to the farmer. He is relieved from the pressure of seed time and harvest, and has time to enjoy his possessions. There is even more pleasure in distributing his hard earned harvests than in gathering them. He takes pleasure in ministering to the pleasure of his animals, and he has time now to contemplate the grace of well bred horses, the bulk of corn fed Durhams, and the elastic step of his Devon team. He lingers at the stable, plying the currycomb; at the sty, patting the sleek sides of his Suffolks; at the sheep yard, calling his South Downs, as they poke their dusky noses into his basket for the sliced roots and grain. Bridget does not get a chance to feed the poultry now. The master scatters the grain himself with liberal hand, and rejoices in the long train of turkeys, the flocks of geese and ducks, and the multitudinous hens that come flying at his call. Now they put on their most beautiful plumage, snowy whiteness, glossy green and bronze, jet black, and golden yellow—beautiful as they grow, and not less so when they adorn the heads of our village belles. There is comfort in seeing the precious grain disappear, in marking the thrift and happiness of his fowls, and the outworking of their social life. He remembers the proverb, "There is that scattereth and yet increaseth; and there is that withholdeth more than is meet, but it tendeth to poverty." He enjoys the more leisurely pursuit of business, and has time for mental and social culture, for reading, for farmers' clubs, and for the literature of moral life. Amid scenes like these he has no occasion to envy Bullion's bloated prosperity. With a cheerful and a thankful heart, he now welcomes the storms of Winter, and the CLOSE OF THE YEAR.

Calendar of Operations for Dec., 1862.

SUNDRY HINTS FOR THE SEASON.

The Farm, Household, etc.

Vegetation is now taking its long nap, beneath the spotless, fleecy blanket which with motherly care good Dame Nature spreads over her offspring. During all the past season, while we have labored, and while we have reaped and slept, the grasses and grains, the trees and fruits, the vegetables and the flowers, have pushed steadily forward; now they enjoy continuous repose. Not so with us. Our hands may be less active, but the mind will be more so. We are shut up from tilling the fields; the time is auspicious for *cultivating the mind.*"

But there is still out-door work to give active exercise enough to the muscles to keep the physical system in order. In addition to the daily round of labor in caring for the live stock, there are tools and implements to make or repair, the summer's fuel to provide, fencing materials to get ready, marketing of farm produce, hogs to fatten and slaughter, ice to gather, schools and school-houses to be visited: and that most profitable of all farm operations in the older states, increasing the heap of good compost manure. Now is also the time to attend well to the

Accounts—Farmers do quite as large a proportion of their business on the credit system as any other class of men. Very few know from week to week just how their store accounts stand. They leave the affairs there to the merchant. A multitude of transactions with their neighbors are on credit, with no record but the memory, and how many lawsuits grow out of the differences in memories. The farmers of this country will not close up all their transactions of this past year without spending in the aggregate several millions of dollars in fees to justices, pettifoggers, constables, jurymen, witnesses, etc., most of which would be saved if a regular system of account-keeping everywhere prevailed. A regularly kept daily account book, the simpler the better, is one of the best witnesses a man can bring into court, if so unfortunate as to need to go there.——The farmer also deals on credit with his fields, his stock, etc. He should keep such an account with each that the profit and loss can be known. This month, get all accounts adjusted, if not settled.

Buildings—The barns should be looked to. A nail hole in the roof, or a clapboard off, may let in snow or rain enough to spoil a dollar's worth of grain or fodder—perhaps ten or twenty dollars' worth. A lightning rod may save the results of a season's labor. Air-hole in the stalls may require several extra dollars' worth of feed to keep up the temperature in the body of the stabled animals. A shed, and side protection against winds will save many pounds of flesh, or of food to produce it, on each animal that can not be stabled this Winter. An extra pound of hay, at least, will be needed to dry off the rains or melted snow from the fleece of an unsheltered sheep.—Tightening the window sashes, and nailing down the loose clapboards will save many times the labor, in lessening the fuel required in-doors. A bank of earth, or better of tan-bark, against the outside of the walls may save the vegetable stores in the cellar; bad air, or too much warmth within may destroy them. A coat of paint on the clapboards, or on the fences, may preserve them many years longer.

Cattle—Two good, well-conditioned animals are worth more in Spring, than three or four which have barely survived the winter. If the shelter and forage are just sufficient for five animals during winter, better sell the sixth one for a song, or make "crow meat" of it at once. Divide the supply for five among six and they will all come out weak. Six cattle well sheltered, regularly fed, watered and salted, and frequently curried, will eat less than five left to rough it through the cold and storms of winter, and the former will all be far more valuable in Spring. Cattle are as likely to die, or be sick and pining with "colds and consumptions," as the human animal. A well kept cow bears a calf worth twice as much as an ill kept one. Well kept oxen are ready to begin the spring work effectively, and do twice as much as those barely getting through winter. To sum up, taking good care of cattle pays well every way. It does not pay to invite crows to a carnival on the flesh of dead animals.

Club Meetings for Social and Mental Improvement should be held in every neighborhood. They need not and should not be formal and embarrassing, but evening visits, where conversation is unrestrained. They thus contribute to social enjoyment as well as practical improvement. For young farmers, a debating club in which the questions for discussion are of practical agricultural and horticultural interest, tends to develop skill in the use of language, argumentative power, and capacity for public life, besides eliciting useful knowledge.

Fencing Materials—Cut timber when other work is not pressing. Some strip off the bark at once to secure rapid seasoning. This prevents the timber from being worm-eaten, and, perhaps, also from rotting, especially between the bark and wood, where decay soonest begins.

Fodder—The scarcity and high price of hay in many parts of the country, owing to the dry weather, makes it doubly important to be economical in its use. We have kept horses and cattle in very good condition when their principal food was corn-stalks, cut very short and wet up with a little bran for the cows, and a mixture of bran, shorts, ground oats, and corn for the horses. Racks or other contrivances are essential to keep animals from wasting hay. It pays to cut up all hay and straw and wet it before feeding.

Hogs fatten much more rapidly on the same food in warm weather, or if provided with a warm, clean pen or a sleeping place in the straw-yard. Pure water, in abundance, is essential unless fed on moist food. It is generally agreed now, that cooking or steaming food for hogs pays a good return for the cost and trouble. See Prize Article on hogs, page 235 in August *Agriculturist.*.

Horses, perhaps more than other animals, enjoy and thrive upon what suits the human animal, such as light, well-ventilated, neat apartments, free both from cold drafts of air, and from filth and foul vapors. They "catch cold" easily, and being driven at a higher speed than any other animal, are more apt to be affected by cold when tired or left to stand, after a perspiring chase, without being well blanketed. A curry comb and brush are as useful to a horse as washing and bathing to a man.

Ice—See p. 297, Oct. *Agriculturist.* As there shown, it costs little to keep ice all the year. Rough boards nailed on the outside and inside of posts, with saw-dust between, good drainage below, and roofing and ventilation above, will preserve it as well or straw upon the ice, as the essential things. The longer keeping of meats and other food, including bread, cakes, pies, cooked vegetables, milk, etc., generally pays for the cost of ice. The first clean, thick ice, is usually the best. In cold localities, a mass of ice in the form of great blocks may be secured by letting water spurt out from the house in a spray from jets in a pipe or vessel.

Manure—See important hints in last month's Calendar. Ten or fifteen loads of manure on an acre, with no additional outlay for preparing the ground, for seed, or for labor, will often increase the crop by as many as 30 to 40 bushels of corn, 15 to 100 bushels of potatoes, 1 to 15 bushels of wheat, besides leaving the soil in much better condition for the next crop. Every hand ful of manure in a corn hill will add one or two plump ears, of better quality, and more stalks for fodder. It always *pays* to save and apply every atom of manure possible, except in some of the new fertile regions. The man who saves the largest heap of good manure, protecting it from all washings, will be the one who will get the largest and most profitable crops next year, be the weather good or bad.

Muck—Hunt muck, dig muck, haul muck, and use muck, abundantly. It is a far cheaper source of fertility than anything that can be bought. Put muck in the stables, in the sties, and in the cattle yards, to suck up all the liquids. Use all practicable in this way, and pile up more of it, sprinkling and mixing it well with lime or unleached ashes. *Every plant that grows furnishes, in its decay, nutriment for every other plant.* The rich black prairies are simply muck beds, the product of previous vegetable growth. Every farm has some muck; the black soil in the lower grounds are vegetable matters produced there, or washed down there. Save and use all such depositles, the more the better. It *pays* to do so.

Milch Cows—"*Ex nihilo, nihil fit,*" (out of nothing, nothing is made), was the infidel adage of the ancients; it is true, however, so far as all human operations are concerned, and no one can expect the cows to make milk out of nothing. The more good fodder, the more good milk. A cow well sheltered and regularly fed and watered, in short, made comfortable, will yield much more milk from the same food, than one kept uneasy by cold or by irregularity in her food. Succulent food, potatoes and other roots, cabbages, apples, etc., show marked effects in the milk pail. Pumpkins are also very good, but it is advisable to remove the seeds which promote flow of urine, to the loss of milk and flesh. Moistened or scalded bran and shorts are also excellent sources of milk. A bushel of bran per week will usually increase the milk by 2 or 3 quarts per day, which is worth much more in Winter than the cost of the material. We have tried and proved it often; so have many others.

Poultry—As with the cows, so with the poultry, "*ex nihilo, nihil fit.*" The hens will try to continue their species, by laying eggs, when confined to a grain diet; but as a rule, the more animal food, the more eggs. If they can get no animal food otherwise, they will even peck out and eat each others feathers or quills. Their natural food embraces insects and vermin, and when allowed to roam at large to find these, they lay well. To get eggs in Winter give them all the odd bits of fresh meat, lime, etc. Butchers' offal is a cheap source of animal food for hens. We use scraps from the fat trying establishments, buying it in cakes of from 50 to 100 lbs., and throwing them into the yards where they lie until gradually pecked to pieces and consumed. This material costs from ½ cent to 1 cent a pound—usually 1 cent, and it is the cheapest meat we can get for poultry. Grain is good for fattening fowls. Water always accessible, or regularly supplied, is as necessary for fowls as for other animals. They eat the kitchen offal as readily as pigs, and turn it to more profitable account. Avoid giving them salt food. Comfort—that is, shelter from storm and wind, with good feeding—is the best "hen-preserver" we know of. Whitewash on every inch of the poultry house, will keep out lice. A bed of unleached ashes to roll in, is a good protection against the small vermin. Lime in some form, as oyster shells, bones finely powdered, is needed by laying hens; gravel, or course sand, is needed by all fowls.

Schools—See important hints in last Calendar. The man or woman who drops into the school house often, and shows an interest in the pupils and in their comfort, is a public benefactor. Both teachers and scholars are encouraged to good behavior and to extra efforts. Who does not remember the stimulus to the whole school, of a visit from a parent or other person? A school visited two or three times a week, the visitors insisting that no show or change of programme be made, but that all things go on in regular course, will generally be twice as prosperous as the school not visited. No one should leave it to others to attend to this matter. The public school should be the pet and pride of every good citizen of the district. Visit it often as a recognised friend, not a morose critic. If the good deeds be sought out and appreciated, an occasional hint for improvement, in a kind tone, will be kindly received and acted upon by both teachers and scholars. Speaking evil or disrespectfully of the teacher in the hearing of your children, or to those who will repeat the words in their presence, inflicts a lasting injury upon them. Get the best teacher possible, and uphold him, or her, so long as employed, *for the children's sake.* We have known a school deprived of all efficiency, by a thoughtless word about the teacher dropped by a parent in presence of his child, and repeated by the child to other scholars.—A dollar or two extra from each parent is sometimes needed to stimulate a good teacher, is repaid a thousand fold in the present and future. Just as the twig is bent the tree's inclined.——One hint more. Thirty to fifty children in a close, unventilated room 15x20 feet, breathing over and over the foul air, is next to the "black hole of Calcutta." The brain is dull; the feelings of teacher and scholars are morose; and the health of all impaired. Ventilate the room well, but not in currents of air from the window, nor through cracks in the floor to chill the feet, which should always be kept warm. The ceiling or at the top of the walls is the place for ventilators. Let the floors be very tight and warm; the feet of those sitting still are most likely to suffer.

Sheep—See last month's Calendar again. Nothing pays better now, or is likely to, than sheep growing, where bad laws, and worse public opinion and custom, do not harbor and protect miserable sheep-killing curs. The ghosts of 28 lambs murdered sheep, murdered in one day by these pests of farmers, ycleept good neighbors' watch dogs, and scores of other sheep lost in the same way on the pastoral Western farm, always haunt us when we write a word encouraging sheep raising. But, happily, a better state of things is beginning to prevail.——Good feed, reg ular watering, careful protection from rain, snow and biting winds, are repaid with large interest by sheep.—— "Like produces like;" ten or twenty dollars extra now in the purchase or rent of a good buck, will be returned doubled, if not quadrupled, in the better lambs next season. It costs no more to feed and raise a sheep worth six or eight dollars, than one worth two or three dollars for wool or mutton.

Tools—There is a wide difference between working with and without implements. The amolunt of the difference depends upon the perfection of the implements. One man costing $1 a day for board and wages, will cut as much wood with a first-rate ax, as two men costing $2 a day can cut with poor axes. This is six dollars a week. Does it pay to buy a poor ax because it costs 25 cents or 50 cents less? The same reasoning applies to all other implements. Are all the tools well taken care of? Housing and greasing the plow, which may take ten minutes time now, may save half a day next Spring in hunting after, fixing up, getting the rust off, and starting it well to work. That half a day may prevent the putting in of half an acre of corn or other crop. The wood work if exposed to the weather, may give way at a critical time. Take care of the tools this forenoon; something may hinder the work in the afternoon. Coat all iron and steel implements

with a thin film (rubbed on with a cloth) of 3 parts lard, and 1 part resin melted together.

Winter Grain—It is expansion of the water in the soil by freezing, that breaks and tears the roots of plants; keep the soil as dry as possible during Winter, by clearing the drains, opening the dead furrows anew, and seeing that the outlets are free. Better run a one-horse plow through the dead furrows when unfrozen this month, especially in moist land. A little grain will be destroyed, but this seldom comes to much in the dead furrows, while the better draining of the rest of the land will largely increase the product thereon.

Orchard and Nursery.

Fruit and other trees are now at rest, so to speak, and there is not much to be done with them, though here are a few hints worthy of attention: Where the ground is open, and not overwet, trees may still be transplanted. The soil will settle around the roots and they be ready to start into growth with the first approach of warm weather. See remarks last month. All trees set in Autumn are better off if well banked up with earth, even a foot or more. This holds them more firmly against swaying of winds; it protects them from gnawing of mice; it sheds off water and melting snows, and prevents alternate freezing and thawing of the roots. A single hard freezing with gradual thawing seldom injures the roots of trees; the frequent thawing and freezing of wet soil is what breaks and tears the rootlets. Fig trees are best protected by bringing the branches together enough to set a barrel over them, and filling this with earth—putting one barrel on top of another if needed by the light. Tender raspberries, blackberries, and grape vines, when bent down and covered with earth, come out well. Why not protect the hollest apple, peach, plum, pear, and other trees likely to be injured, by banking earth high around them? It will certainly pay to take this little trouble with trees specially valuable, and probably with all kinds, particularly the first year. Stake and tie trees newly set out, if likely to be swayed by winds. Three stakes with a band of straw around the trunk tied to each stake, will hold them firmly, and prevent their being blown out of position, and the breaking of the roots.

The trunks of trees are often blackened and deadened, especially in very cold localities, by freezing at night followed by exposure to the hot rays of the sun, in the day time. This may be prevented by setting up on the southeast side, branches of evergreen trees, as pine or hemlock, where readily accessible. Or the bodies may be encircled in straw, not thick enough to harbor mice. A Michigan farmer in a note to the *American Agriculturist*, recommends binding newspapers around the trunks. Snow, when liable to break or crack the branches, should be jarred off in time to prevent this.

Mice are sometimes very destructive. At the time of this writing, the ground is dry; if Winter closes in without filling up the soil with water, mice will abound and should be carefully guarded against. The very dry Autumn four or five years ago was followed by greater destruction by mice than any previous year within the recollection of the oldest inhabitant. They bred and multiplied all Winter in the dry soil, and made great havoc among the fruit trees. They seldom attack exposed trunks, but make their way under light snow. Banking with earth or tramping the snow hard around the trees keeps them away. No grass or weeds should be left around the trunks as a harbor for vermin. The bark of young trees is most relished by mice, and these trees should be carefully guarded.

Cions may be cut now, or at any time during Winter when not frozen. Keep them in fine, moist, but not wet soil, in a cellar or cisewhere, where they will be cool, but not frozen. See that each bundle of them be rightly marked. Cions should be cut from vigorous trees, and from straight thrifty shoots of new growth. It is said, though we can not vouch for it, that cions taken from the lower branches come into bearing soonest, while those from the top branches make handsomer, thriftier trees.

Preparing for Spring setting of trees may be done now. The soil plowed up deeply now, or before this, will be ameliorated by freezing and thawing, and be better prepared to receive and nourish trees set out early in Spring.

Draining is the most important preparation for fruit trees. A soil made dry and warm by deep draining will, other things being equal, yield twice as much fruit as if not drained. The trees suffer far less in Winter, and will grow and yield much better during the Summer season.

Mulching the ground with a good coat of manure over the roots of trees as far out as they extend, serves more than one good purpose. It not only washes down into and enriches the soil, but it keeps in the frost later in Spring, and thus prevents the too early starting of the sap and buds. This last will be an important matter, if the season open early and hard freezing afterward occur. We speak from experience, from much observation, and from the philosophy of the matter, when we say that trees protected by a few inches of manure around them will in nine cases out of ten, yield the most certain, the most abundant fruit by far. Try the effect upon at least a few trees. If the mulch be thick enough to keep back the fruit buds to an unusually late date, you will be almost sure to get fruit—apples, peaches, pears, plums, cherries, etc.

In the Commercial Nursery, root-grafting, preparing stakes, labels, tallies, planning for the Spring sales, advertising the public what you have in store for them, etc., will furnish abundant occupation. See Hints to Nurserymen on another page of this paper.

Kitchen and Fruit Garden.

Even in this month, there are some things to be looked after. Utility before beauty may be the necessary rule, and so masses of weeds, straw and manure must, perhaps, remain where they are needed to protect plants left in the ground. But when not needed, it adds to one's enjoyment to look out upon a "cleared up" garden plot. It is well therefore, to gather up the stumps of plants, and to rake off the ground clean as if for a new seed bed. The Summer vegetable garden may thus be a Winter lawn.

It always pays, however, to dig or plow the garden soil into high ridges, and let the frost operate deep downward. That noxious subsoil will be rendered wholesome, if Jack Frost be admitted to pulverize it to his liking. The longer parsnips and beets and parsneps, the larger potatoes, the more vigorous above-ground plants will tell next Summer. If manure be ready, dig it into the soil this month if practicable. The frost will help it also, and it will mix with and soak through the soil much better than if worked in hurriedly in masses in Spring.

Asparagus Beds—If not already done, put on a coating of several inches of good horse or other manure, at once. The plants will be thus protected and be ready to start earlier and more vigorously.

Bean Poles and Hop Poles will last twice as long if put under cover half the year. Now, before the ground is deeply covered with snow, is a good time to procure a supply for next season. Time is too precious in Spring to stop to hunt them up. Everybody wants them for Lima beans, one of the best and most nutritious products of the garden—good to eat at home, and now retailing in this city for 16 cents a quart, and for more in Spring.

Brush for peas and tomato vines, and nasturtiums, can best be gathered now. Cabbages and other vegetables stored need frequent inspection to see that decay at some point is not beginning to act as a "yeast" to the heap.

Celery left in the ground may need an extra coat of soil to keep out too-hard freezing, or rather to prevent thawing. We always leave it where it grew, deeply covered as required, and as wanted all along through the Winter; cut out cakes of earth if frozen, carry them to the cellar in baskets, and let the soil thaw gradually. The celery comes out unharmed—rather sweeter and tenderer for the freezing.

Cold Frames need extra covering of mats or straw in severe cold weather, but as much ventilation as the state of the atmosphere will admit.

Clons and Cuttings of grapes, fruit trees, currant bushes, etc., may be made at any time now. See under Orchard Calendar above.

Manure—Let abundant stores be now in process of gathering and manufacture—leaves, muck, vegetable refuse—all increase the value of the compost heap. Every gill of water running from the heap is a waste of fertility. If without shed conveniences, a few boards will turn off washing rains. Keep in mind what a cubic yard of good manure will do for a square rod of ground, and then make good use of the rule of multiplication.

Planning—Now is a good time to begin to plot out the garden ground, and then during Winter let (good) seeds for each plot be provided. A garden of moderate size well planned for variety and succession, will supply the table with agreeable food, daily, from the first cutting of asparagus and the early pie plant, until the last gathering of beets and turnips in late Autumn. Decide upon at least one or two new vegetables to be added next season to the old routine of lettuce, cucumbers, beets, onions, potatoes, cabbages, peas, string beans and green corn. There is okra for excellent soup; nasturtiums for the best pickles and beautiful flowers as well; spinach for greens all Summer and (we have it) nearly all Winter; cauliflower, the best of the brassica tribe; it is good early and late, and pickles finely for Winter use. Of these and others, and of the garden fruits, we shall speak more hereafter.

Raspberry and Blackberry canes of all kinds go through the Winter better, and bear much more abundantly and certainly, if bent over and covered with an inch or two of soil. For the tender sorts, this is essential. It takes but a few moments' work.

Seeds—It is better to buy good seed at any price, than to have any thing but the best free of expense. But all good home-grown seeds should be carefully saved from moisture and freezing, from a hot or very dry atmosphere, from a changeable temperature, and from vermin. Seeds will be high next Spring. It now costs double the usual price to get them from Europe. The wet season there, the 10 per cent. duties added, the premium on the currency to pay the duties, and the cost of the exchange to pay for the seeds, will double the price of the large supplies of seeds we have annually obtained from across the Atlantic. Save a few of the best beets, turnips, cabbages, etc., to raise seed next Summer.

Spinach is one of the first Spring vegetables. At the South it may still be sown, but it is too late in this latitude and further North. The Winter spinach remains green all Winter, and may be cut at any time when not frozen or covered with snow. A slight protection of leaves or straw is necessary.

Strawberries—Experience shows that all kinds of strawberries even south of this latitude, fruit better if protected with a slight covering of tan-bark, or leaves or straw. Too much covering smothers them. The rapid thawing and alternate freezing and thawing almost daily when not protected injures the plants.

Flower Garden and Lawn.

Roses and other hardy flowering shrubs, and also hardy shade and ornamental trees, may be planted out, as long as the ground remains unfrozen. Laying out grounds, grading, making carriage drives and walks, etc., may also still be done. This comprises about all in the line of permanent improvements that is now practicable.

Chrysanthemums—Blooms may be preserved until Christmas by merely potting, and removing to the house. Defer dividing roots until Spring.

Evergreens—The lawn on which evergreens are plentifully interspersed, and tastefully located and trained, presents a spectacle that, in Winter especially, is beautiful indeed, and highly in contrast with the naked, skeleton-like appearance of other trees. The evergreens will need a little care to remove excessive burthens of snow from their branches immediately after hard storms.

Flower Pits will require particular attention to keep them sufficiently protected and ventilated.

Lawn—It is not too late to give a light dressing of fine manure and ashes, leached or unleached, if needed. Rolling is also practicable and beneficial in many cases.

Wall-climbers—Protection to tender varieties may be given by making a light wooden frame to set against the wall over them, covering the frame with old carpets, or other material. Of course such vines as may be taken down and laid on the ground can be protected then with less trouble and expense.

Walks are best made by excavating a concave bed about eight to twelve inches deep, with a ditch for draining in the center. Fill the ditch with rough stones, and also the bed to within about three inches of the surface. Then fill up with gravel and sand, and roll thoroughly. Thus made a walk will *stay* made.

Green and Hot-Houses.

Great care will now be requisite to keep up an even temperature, which should not be suffered to fall below 35°, nor to rise above 45° in the green-house; in the hot-house the limits are from 55° to 65°. Where a collection of cactil is kept, 40° is the lowest limit of temperature. A small neglect, especially in localities where sudden changes of weather are common, may sacrifice much.

Large open tanks of water in the house contribute to the equalization of temperature, and also promote the moisture of atmosphere so essential to the welfare of the plants. This moisture is also promoted by frequent syringings or sprinklings.

Mildew—On its first appearance dust affected plants with sulphur, or syringe with sulphur water.

Ventilate thoroughly, especially on mild days, when the house may be thrown open. Also admit a good degree of light. Shutters should be provided for severest weather, but should be kept on only when necessary.

Stimulate plants beginning to start with dilute liquid manure, repeating fortnightly, until in bloom, and no longer. Exterminate insects by washing with strong tobacco water, rinsing it off thereafter with fresh water,

Containing a great variety of Items, including many good Hints and Suggestions which we give in small type and condensed form for want of space elsewhere.

Who wants a Premium!—Our valuable premiums (except No. 11,) are continued (see page 375). These certainly afford a good opportunity to secure some first-rate article wanted, and at the same time to benefit a whole neighborhood by getting the people to read, and think, and make improvements. Will not a paper like the *Agriculturist*, if read for a year in most of the families of a neighborhood, work out some changes in the habits of thought, in the subjects of conversation, and in the fixing up of matters generally?

Note to Correspondents—Explanation.—We are glad to receive all of the thousands of notes, queries, and items of information sent in; but it is not possible to use them all—at least not promptly. From the mass of questions, we first select those which we feel best prepared to answer correctly. Others are put on file until such times as we can hunt up the information, and this can not always be found. Others are sent to persons who can respond better than any one connected with the office—our rule being to always get the best information possible. It thus sometimes happens that several months intervene before an answer appears. Again, the most important, or the most seasonable subjects, or those of most general interest, receive the first attention. And, still again, a great many questions are asked, which are of not the slightest interest to any one but the writer. We have no right to use, for such questions, space in the paper which belongs to a large circle of readers. When possible, and it is not always so, we answer such questions by letter, preferring to expend time, postage and stationery, instead of space. A general rule is, to throw into the waste basket all communications not accompanied by the writer's name. The reasons for this sweeping rule may not always be obvious to others; a brief editorial experience would make them so.

"Much in Little"—Read the Calendar.—Our readers will notice that the pith or substance of a large number of articles, is condensed into the closely printed *Calendar of Operations*, on pages 354 and 355. With far less labor we could have "spun out" the Calendar to have filled up all the pages devoted to larger type: but our aim is to pack into these pages as many hints and suggestions as possible. If our readers did not appear to prefer the present type, we should print the whole paper in the smallest letter, and thus give still more reading matter.

Our Exhibition Tables.—In addition to the large display of Pumpkins, Squashes and Gourds, (reported on page 362,) our tables have presented many objects of interest during the past month, kindly contributed for the public pleasure by a great number of public spirited persons. The space required for the Index compels us to leave over to next month the report of the articles and contributors. We shall be much pleased to have new contributions come in during all the Winter. These tables may be, and indeed have been as interesting as a county fair, and they are open free to the public at all times.

Improved Aster Seed for Distribution.—No flowering plant is more desirable than the China Asters as they have been recently improved by the French and Germans. Some of the flowers are nearly as large as dahlias in size, and far more beautiful in the fineness of their petals. During the past year we have grown about half an acre, to produce seed for free distribution among our subscribers. Owing to some peculiarity of the season, part of the seed blasted, while the most perfect blooms never yield more than a few seeds. Still, we shall have enough of perfected seed to present a dozen or two seeds, or more, to every subscriber desiring them. They will be announced in our Seed Distribution next month.

A Criticism and an Explanation.—A correspondent, who is "nothing if not critical" writes: "....How often you introduce the *American Agriculturist* into your articles. Is not this over-done?"—We give our correspondent full permission to always skip these words when he finds them; but will just say by way of explanation, that more than a thousand other journals receive the *Agriculturist* regularly,—some as an exchange, and some subscribing for it. Most of these have an "agricultural column," and draw largely for this column upon the matter in the *Agriculturist*. Of course the editors usually (not always) intend to give due credit for articles or information that have cost us time, labor, study and investigation, or money. But some *printers* have an inveterate habit of dropping out the credit. In this way, hundreds, yes thousands of good articles have been copied, and then re-copied, without credit, or perhaps with the credit given to the last journal that used them. From careful examination, we find that more than half of all the good and valuable articles, on farm, garden, and household work, now "going the rounds of the papers" unredited, were originally prepared for and published in the *Agriculturist*. So, to mark our own property, we frequently introduce the name of this journal into the substance of an article, where it can not be left out in copying, except intentionally; even this is sometimes done.

Five Dollars Extra.—For three or four years past, we have been sending this journal to one of the most thorough, intelligent, and successful farmers in the country, in return, as we supposed, for his occasional contributions of useful suggestions for our columns. A few days ago the following note accompanied a letter on farming topics: "By the time the *Agriculturist* comes, I feel ashamed at receiving it so long without compensation, for your paper really gives more useful information than any other paper I read; at least it does so in many things very essential to the farmer. Please find enclose $5, as compensation, in part, for the pleasure my family and myself have taken in reading it. Your sincere well-wisher, ——." This is from a man whom we never saw but once, and that was on his well-cultivated farm, nine years ago. His table was then supplied with all the leading agricultural journals of the day. Such kind words of approval, from such a source, are a far greater stimulus to future exertion in our calling, than any pecuniary consideration, though the sum received is by no means unacceptable in these high-priced paper times; it will also enable us to add so much extra to our contributions to aid the soldiers.

Come and See the Pumpkins, etc.—Some of the finest specimens exhibited are decaying, and several are already gone, but there will be, for several days yet, a display worth seeing by those who can make it convenient to call before they are all gone.

Raising Water with a Pump.—W. B. White, Marion Co., Va. There will be no trouble in bringing water in a pipe, up an inclination of 30 feet, perpendicular high, and 65 feet distant. A common suction pump will raise water 30 feet, and bring it through some hundreds of feet. The greater the hight of pipe, the more friction. Theoretically the raising power of a pump depends upon the hight, and not upon the length.

How to Use Muck.—E. Sheldon, Cattaraugus Co., N. Y. It is seldom, if ever, wise to cart muck from the swamp directly to the field and apply it to the growing crops. A better way is to cart it out into some open corner of the lot, and lay it up in heaps, mixing in lime or ashes, say an inch of lime to each foot or so of muck. After it has lain two or three months, shovel it all over, and mix well together. A still better way is to cart it into a shed, and use it as an absorbent of the liquid manure of the stalls. Such a compost is very good, and effects an important saving of liquid manure.

Cotton in Pennsylvania.—John Oliphant, Fayette Co., Pa., sends to the office of the *American Agriculturist* a very good sample of cotton grown by himself. It was not planted until late, otherwise Mr. O. thinks he would have ripened all put in. He thinks it will be a paying crop there even at half present prices. P. S. Other samples are coming in just as we go to press. They will be noticed hereafter.

"Rags" at a Premium.—The most independent man we know of just now, pecuniarly or otherwise, is the one who most abounds in rags. Good white rags which the gatherers but recently took from economical housewives as a favor to them, at 1½@2 cents per pound, paying in "tin ware," are now in quick cash demand at 10 to 14 cents, in this City. Their bulk, and troublesome transportation, makes the country price considerable less; but all the family rag-bags in the country can now be emptied at double or triple the old prices, and for cash at that. Good housekeepers will do well to make a note of this. It will not take a great number of pounds to pay for the *Agriculturist* a whole year, and one gets back in the *Agriculturist* all the paper made from four or five pounds of nice white rags, in the course of a year.

Flax Tow Wanted—Hemp.—Recently a number of paper manufacturers and dealers have called at the *Agriculturist* office to inquire where flax and hemp, especially flax, are largely cultivated.—They keep quite private as to their reasons for the inquiry, but we strongly suspect it has something to do with an attempt to turn tow, and perhaps hemp waste, to account in making of paper, owing to the scarcity of rags. Will our readers please report any facts they have in regard to this crop, where grown, etc., it may perhaps be of mutual advantage to both manufacturers and flax growers.

Grape Vines for a City Yard.—"A New-York citizen" writes: "The *Agriculturist* has convinced me that I can derive both pleasure and profit from having a few grape vines in my city lot, to train against the house and high fence. I have room for only about four vines, and would like as many varieties. What shall I get, and where?"—*Answer.*—Try an Isabella, a Concord, a Hartford Prolific, and a Delaware. Except this month, you will usually find them advertised in our columns by several reliable growers; or you can get them through Lane's Purchasing Agency, at 151 Nassau-street.

Books Wanted for Sick Soldiers.—A Hospital for invalid soldiers has been established on David's Island near this City, where a large number are constantly receiving attention. A library for their use has been commenced, and contributions of suitable books and magazines are solicited. No better disposition can be made of the thousands of old volumes of readable matter which have been perused and are now lying useless in the houses of many families. They should be sent (free of cost) to "Evangelical Knowledge Society, No. 3 Bible House; or to William E. Dodge Jr., 19 Cliff-st., N. Y.

Shaver's Eraser, Polisher, etc., is a neat little instrument for the writing desk, serving the quadruple purposes of an eraser, polisher, paper-cutter, and folder, and also as a pencil-sharpener, costing from 50c. to $1, or more, according to the style of finish. It is manufactured at New-Haven, and furnished quite as cheaply as the less convenient imported article.

Book on Implements.—W. Ellis, Fairfield Co., Conn. The Young Farmer's Manual, by S. E. Todd, contains good, practical, common-sense directions respecting agricultural tools and implements, together with a large amount of other excellent matter relating to farming. We can forward it post-paid upon receipt of the retail price, $1.25. Thomas' Farm Implements is also a good book on the same subject; price $1.

Double Hyacinths.—"Flora." The first double hyacinth was obtained in the year 1710, or thereabouts, by a Hollander, of the name of Peter Voerhelm. The "hyacinth soil," of which the Dutch have so long made a secret, is simply this: Of rich garden soil, four parts; of sand, four parts; of black mold and cow-dung mixed, three parts; rotted leaves, one part.

The Calceolaria.—"Jane," Syracuse, N. Y. It was first brought into Europe, from Chili, in the year 1773, though, for some reason, it was not much disseminated until 1830. It has been wonderfully improved by hybridization. In 1832, the Messrs. Young, of Edinburgh, sold some of their new hybrids for $10 the plant.

Silkweed or Milkweed, (*Asclepias cornuti*) is the name of the plant bearing pods, sent by P. C. Wadsworth, Town Hill. Its uses are referred to on page 325, November *Agriculturist*.

Cider Wine.—The Country Gentleman gives the following from a correspondent: Take pure cider, made from sound ripe apples, as it runs from the press, put 60 lbs. common brown sugar into 15 gallons of cider, let it dissolve, and fill clean sweet casks with the mixture within two gallons of being full; put them in a cool place, leaving the bungs out for 48 hours; then bung up, leaving a small vent until fermentation wholly ceases; then they are to be bunged up tight, and the wine will be fit for use in one year. It improves with age, and may be left upon the lees.

Medicine for Summer Complaint.—"F. M. H.," probably a physician of this city, thinks the recipe published on page 230, August *Agriculturist* calculated to do harm, as the proportions are not given. Besides, he says, there are so many forms of Summer complaints (derangement of the alimentary canal) that only a skillful physician can properly distinguish and prescribe for them. Pure air and proper diet are recommended as the best preventives, and a good physician to effect a cure.—We seldom notice communications, when not accompanied by a responsible name.

Correct Use of Terms.—D. D. Prettyman, Salem, Oregon. As *custom* forms our language, and as custom invariably puts bread before butter, "bread and butter" is preferable to "butter and bread."

Fattening Qualities of Sheep.—Experiments instituted by Mr. J. B. Lawes, of England, to determine the relative aptitude to fatten, of different breeds of sheep, resulted as follows: To make 100 lbs. of live weight, the Sussex breed consumed 297¼ lbs. of oil-cake, 285¼ lbs. of clover, and 3,835¾ lbs. of Sweedish turnips; the Hampshires, 291½ lbs. of oil-cake, 261¼ lbs. of clover, and 3,966 lbs. of turnips; Cross-bred wethers, 264½ lbs. of oil-cake, 251¾ lbs. of clover, and 3,725¼ lbs. of turnips; Cross-bred ewes, 263½ lbs. of oil-cake, 250¼ lbs. of clover, and 3,671 lbs. of turnips; Leicesters, 263¾ lbs. of oil-cake, 251¼ lbs. of clover, and 3,761 lbs. of turnips; and Cotswolds, 253½ lbs. of oil-cake, 216¾ lbs. of clover, and 3,557 lbs. of turnips.

More Good South Downs.—Hon. E. Cornell, Prest. N. Y. State Agricultural Society, has received in excellent condition nine very fine South-down yearling bucks and fifteen ewes purchased hy him at the final sale of Jonas Webb's flock. We are glad to notice that Mr. Cornell proposes to let the bucks. This opportunity to improve their flocks should not be lost by breeders.

Increasing Weight of Wool.—E. T. Hardy, Floyd Co., Iowa. The weight of wool will not be increased by exposing sheep to the full severity of Winter. Its growth depends largely upon the good condition of the animal. If poorly fed, the scanty nourishment, after sustaining life, will leave little surplus to be appropriated for wool. Shelter during excessive cold, diminishes the amount of food needed to supply animal heat, and more food therefore goes to producing wool.

Buckwheat Straw unfit for Bedding.—W. A. Floyd, Orange Co., N. Y., writes to the *American Agriculturist* that buckwheat straw used as bedding for animals causes an eruption upon the skin, which though not especially dangerous causes great irritation and discomfort. Rye or oat straw is every way better. [This may be so, but we have thought the prejudice against buckwheat flour and straw, as being productive of skin diseases, to be a mere fancy.—Ed.]

Cut Straw for Bedding.—L. D. Weber, Luzerne Co., Pa. It would hardly pay to cut straw by hand for hedding a large number of cattle. Where a horse-power cutter is used, it may be advantageous. The cut straw is much more readily mixed with manure and rotted, and the soiled parts of the bedding are more easily removed without waste. Four to six inches in length is sufficiently fine for bedding.

Grain for Young Animals.—C. T. Wilson, Cayuga Co., N. Y. A small amount of grain fed to young animals in Winter will improve their growth and strength. It is not best to make them fat by overfeeding; give only enough to keep them thriving. More animals are stunted by insufficient food while young, than are injured by too early graining.

Value of the Milk Crop.—It is estimated that the entire milk crop of the United States, for the year 1860, reached $160,000,000. New-York State produces as much milk as all the New-England States, together with New-Jersey, Delaware, and Maryland.

Large Cattle.—W. B. F. Davis, North Berwick, Me., challenges the West to beat a yoke of oxen owned by Capt. Francis Hurd. They were 7 years old last Spring. They stand respectively 5 ft. 4½ inches, and 5 ft. 10 inches high, girt 9 ft. 1 inch and 9 ft. 4 inches, and are 9 ft. 6 inches in length. June 1st, 1864, they weighed 6964 lbs.; Sept. 3d, 1862, they had increased to 8330 lbs., one weighing 4120, the other 4210 lbs.

An Ugly Customer.—C. R. Tyler, of Perry Co., Wis., sends to the office of the *American Agriculturist* the tanned skin of one of the aborigines of that State, a rattlesnake, 5 ft. four inches long, weighing when killed, 6 lbs. Its rattles, 14 in number, indicate it to have been an old settler, and an ugly customer to meet.

Enormous Yield of Buckwheat.—Andrew S. Nash, Westport, Conn., sends to the office of the *American Agriculturist*, a sample of buckwheat which yielded *at the rate of* 2137½ bushels per acre. It should he stated however that the product of only a single stalk with its branches, was ascertained, amounting to 2850 kernels. From this anybody can cipher out the above yield per acre, on paper, *provided* three pecks were sown, and each seed gave a corresponding yield. When any one succeeds in ciphering it out with the plow and thresher, we shall be glad to tell how it was done.

Ice-Houses in Cellars.—T. E. Bennett, Dutchess Co., N. Y. Ice may be kept as well in the cellar as in any other place, if care be taken to exclude air and provide for drainage. Lay scantling upon the cellar bottom in one corner, and build up a double walled box of the dimensions required. Lay a foot of straw upon the bottom and six inches of sawdust or spent tan-bark upon this. Fill in the sides with the same material, and place it between each layer of ice. Finish at the top with an extra layer of straw or sawdust.

Bushel of Grain in Maine.—W. B. F. Davis, North Berwick, writes that in Maine, the statute bushel of corn is 56 lbs., barley 56, oats 30, potatoes 60 lbs.

Cluster Oats.—A. C. Ballict, Venango Co., Pa. The specimen is curious, but is probably only a sport, and not a fixed variety. Such anomalies may sometimes produce a similar succession, but the tendency will be to return to the normal condition. There is a pleasure in experimenting in this line, even though no permanent good comes of it.

Use for Bitter Pumpkins.—Specimens of very bitter pumpkins were sent to the *Agriculturist* office a few years ago and we spoke of them as being of little account. N. H. Lyons, Susquehannah Co., Pa., writes us that they are a good substitute for hops. He cuts them into rings and dries them, after which a piece is boiled in water and the liquid used precisely as one would hops for yeast. He lost his seed by planting too near other pumpkins.

Sorghum in California.—The culture and manufacture of Sorghum in California this year has been very successful. Fields of from five to thirty acres have been grown, and preparations are being made to cultivate on a large scale next season.

---

30 Barrels of Sorghum Syrup per Day.—The Prairie Farmer describes a manufactory at Loda, Ill., where the above amount of syrup is turned out. The mill was erected to accommodate farmers who agreed to deliver 800 acres of cane to be manufactured. Two large grinding mills and a set of evaporators are kept at work night and day, using up about 10 acres of cane in 24 hours. The evaporation is done by steam which also furnishes the grinding power. The syrup is of fine flavor, but rather dark colored, as help can not be had to strip the cane before crushing. The refining process is expected to remove the coloring matter.

Uses of the Roller.—"James." For making and keeping a lawn in fine condition, the roller is indispensable. For farm purposes, it is very useful in the Spring, to press back roots of grain and clover that have been thrown up by the frost; to level down ant-hills; to press into the earth small stones and bones that would otherwise dull the mower's scythe; to crush clods of dirt, and bring the soil into close contact with newly-sown seed; and to give grass a firmer and finer texture.

Keeping Onions in Winter.—H. Warner, Essex Co., Mass. Onions for winter keeping should be stored in a dry, cool place. A little frost does not injure them if kept covered and not handled until thawed out. An upper floor is generally better for the purpose than a cellar, which is apt to be too damp.

Sowing Beets with Carrots.—Rev. J. Fletcher, of Hartford Co., Conn., whose readings of the *American Agriculturist* have led him to experiments of various kinds, has settled upon the plan of sowing alternate rows of beets and carrots, putting in Altringham carrots early in the Spring, 5 feet apart, and sowing white sugar beets between the rows about the 25th of May. He manures heavily, plows deeply, and trench plows by running a light one-horse plow in the bottom of each furrow. He thinks a much greater crop can be thus raised than when on separate plots.

Tansy Tea will Keep off Bugs from the vines of squashes, pumpkins, cucumbers and melons; so says Mr. J. W. Staples, of Orange County N. Y. He informs the *American Agriculturist* that he has tried it repeatedly and always with perfect success. He steeps the tansy plants in a kettle to a strong tea, and then sprinkles it over the vines with a brush. The bugs curl up and drop off, and cease to trouble the vines. A second or third dose is applied after a rain, or when a new crop of bugs comes out. A tubfull of the tea can be prepared at one time, and kept on hand for use as wanted.

Keeping Ants from Trees.—W. Clark, Fulton Co., O. We know no better way to prevent ants ascending trees, than to surround the trunks with sheets of strong paper covered with gas tar. This substance remains sticky a long time, and would prove a hard road to travel for insects. It should not be applied directly to the bark—young trees have been injured by it.

Girdling Trees.—"J. S. jr.," Chester Co., Pa., inquires if the roots of trees can be killed by girdling the trunks at any particular season of the year, so that young sprouts will not start the following Spring. They would probably decay soonest by girdling in mid-summer when the tree is in full leaf.

Evergreens for Shelter Hedges.—O. H. Wadsworth, Moultrie Co., Ill. Evergreen trees are best for screens because they retain their foliage in Winter, and thus break the force of the wind. They should be set in double rows, the outer or most exposed one of pines and spruces, the inner of hemlock and arbor vitæ. In a few years they will form an almost impervious wall about the enclosure.

Evergreen Tree Seeds.—C. R. Griffin, Riley Co., Kansas. Seeds of White Pine, and other evergreen trees can be had of J. M. Thorhurn & Co., this city. They are usually planted in Spring, and will doubtless flourish in Kansas; they grow almost everywhere. It is well to put the seeds in boxes of moist earth during the Winter, or at least to get them into the ground very early in Spring.

Chickasaw Plum.—S. Kinsey, Montgomery Co., Ohio. This is a wild variety not worth cultivating, now that our list of choice plums is so large. It makes a good stock on which to bud other sorts, at the South, but is not perfectly hardy at the North.

Cheap Apples.—One of the Portland (Me.) journals says that a merchant of that city has contracted for 1,000 barrels of good Baldwin apples to be delivered at $1 per barrel.

Origin of the Montgomery Grape.—J. A. Montgomery, writes to the *American Agriculturist*, in relation to the origin of the so-called Montgomery grape, that he procured it from a German living in Lycoming Co., Pa., who could give no definite account of its origin or true name, but who probably brought it from Europe with other varieties. Mr. M. sent some of the vines to Poughkeepsie, N. Y., from which the present stock has been procured by different parties. It is not hardy.

Grape-Growing near Cincinnati.—A correspondent of the Genesee Farmer says that within 20 miles of Cincinnati over 2,000 acres are now cultivated in vineyards, mostly of the Catawba variety.

White Seedling Grape.—F. Kindley, Wabash Co., Ind. Grapes received in fair condition, and we judge them worthy of propagation, as a sweet, vinous grape, with little pulp. The vine is doubtless a seedling.

Michigan Seedling Grape.—Samples received from N. R. Haskell, Monroe Co., Mich., were submitted to the *Agriculturist* Fruit Growers' Meeting, and pronounced to be Catawbas which a favored position or a more vigorous vine had ripened earlier than some immature Catawbas sent at the same time.

Earliness of the Rebecca Grape.—"John." With us, it ripens between the Delaware and Diana, yet improves by hanging long on the vine. It is too tender and too slow of growth, to suit this fast age.

Pears—Winkfield, *not* Wakefield.—Two correspondents take to task the type-setters and proof-readers, and indirectly the editors, of the *American Agriculturist*, for "ignorantly or carelessly always printing the name of a pear, *Vicar of Winkfield*, instead of *Vicar of Wakefield*." The pear in question was obtained from the woods of Clion, France, by a *Curate* living near, and was there called *Le Cure*, (Vicar.) It was soon after introduced into Winkfield, (not Wakefield,) England, and being disseminated thence, it received the name *Vicar of Winkfield*. Our printers and proof-readers are right. This variety is a good bearer, and *has* been in good repute, but there are plenty of better kinds.

Cranberries in Winter.—"Novice." Cranberries should be kept flooded if practicable during Winter, otherwise the frost heaves out the roots, and injures the bearing the following season. We know of no upland variety that gives as certain returns as those taken from swamps, sometimes called upland.

Wintering Stocks and Wall Flowers.—C. N. Doane, Queens Co., N. Y. It will not be enough to cut these down and cover the roots with leaves or additional soil. They must be so kept as not to be frozen. The only really safe place is a pit, house or cellar.

Have you Rhubarb or Pie Plant? This supplies one of the earliest and best materials for pies and table sauce, and is believed to be tonic and healthful. It is very readily grown, and a dozen or fifteen one-year old roots will supply a large family, one year after setting. The Linnæus variety yet stands at the head. It is now quite common, and 1-year old roots or crowns can be purchased of most commercial gardeners and nurserymen. But those who can not get the roots of this variety should sow the seed. This does not always follow the parent plant in character and value, but is likely to produce a good sort, and sometimes even an improved one. We have many promising reports already from seed sent out by us so abundantly the past year, and we shall not be surprised if in several instances the favorite Linnæus be far eclipsed by its offspring. We have again saved several bushels of the purest and best seed, parcels of which will be sent free to all our subscribers needing it. It will be in the seed list next month.

Humbug—A Caution.—Better avoid all the so-called "Insurance Companies" offering to insure soldiers against drafts, sickness, wounds, etc. A magnificent Company (on paper) nominally in Wall-street (really nowhere that we can find) has recently succeeded in humbugging even some of the sharp editorial fraternity, into publishing half a column or more of advertisements, under promise to pay in the future.

Deferred Items.—A large number of basket items are crowded over to next month by the index.

SUNDRY BUSINESS ITEMS, ETC.

1000 December Copies Free.

The extra November edition, offered free to new subscribers, lasted not quite to the middle of the month. Of this (December) number, we will print 1000 extra copies, to be presented to the first 1000 *new* subscribers received for the next volume. All new names sent in prior to Dec. 1st, of course receive the December number, as previously announced.

A Request, and Why Made.

As soon as one number of this paper is mailed, our men commence writing mail wrappers for the next, and these are all called over again and compared with the books, to be sure that there are no mistakes. They are then tied up in bundles for each State, county post office, etc., so that as soon as the printing commences the mailing begins, and follows the presses. But this month, we must delay the wrappers until the renewals are received and entered in their appropriate places in the books. This takes much time and care. We do not wish to put on inexperienced men who might make mistakes, and so our old clerks and bookeepers work almost night and day towards the last of the month. It will greatly lighten the labor, and assist in getting the books regulated, and in the prompt mailing, if our readers will send in as many names as may be convenient very early in *December*.

☞Please always write names plainly, and give without fail the *Post Office*, County, and *State*. Let letters be short, and all business matters on a separate sheet from other topics; put name, address and date, on each sheet.

Two Men

Cultivate the same kind of soil, side by side, with equal market advantages; the one prospers, and the other does not. Why?—*Answer.* One plans better than the other. He gathers all the suggestions from others that he can, and keeps thinking them over himself. Reading about what others do or think, helps a man think himself. Please throw out this hint to a neighbor or two, and ask them to get some good paper, specially devoted to their own pursuit. If they can get no better, let them try the *Agriculturist* for a year.

Send Along the Items.

Anything that our readers can contribute, in the way of successful or unsuccessful experience, queries, hints, suggestions, etc., will supply material, and add to the general fund of knowledge. Just what one cultivator would talk about with his neighbor, concerning his experience on his farm, or in his orchard or garden, or concerning household labors, is just what we would like to have talked over in the *Agriculturist*. It will be fully as valuable when read in printed lines, as when heard in conversation, though some are afraid of anything coming in the form of "book knowledge." Now, when so many thousands are sending in their renewals, let us receive a store of useful material to work up during next year.

☞ Let all such matters be on a *separate piece* of paper from business items, so that they can go to the editors' tables. All money letters are numbered and kept on file by themselves. Each piece of paper should contain the name and address of the writer, and the date.

Great Advance in Printing Paper, but No Increase in Subscription Prices.

A CARD.

Perhaps no other class of persons are now feeling the effects of the war more than publishers. Formerly, a large amount of cotton waste from the cotton manufactories was used in making paper. Now that waste is worked over into various fabrics; and more than this, while cotton rags are reduced to fibre and used in Canton flannel, and even in muslins. As a consequence, "paper rags" are so scarce that paper manufacturers can command their own prices. As an illustration, our paper purchased in advance for part of the next volume cost us nearly a thousand dollars more for *each number* than it did a year ago.—There have been many consultations among publishers, and it has been concluded necessary to advance the rates for papers supported mainly by subscriptions, and by most of those depending upon advertisements. But owing to the prosperous condition of the *Agriculturist* even in this war year, we still keep the price the same, without at all diminishing the intrinsic value of the paper. If the price of paper continues to rise, it may require some sacrifice for the time being, but we prefer this, rather than to vary the terms from what they were twenty one years ago, and have been nearly all the time since. As soon as the four million bales of cotton now locked up in the south are brought into the market (and we are sure they will be in less than one year) printing paper will decline again.

In consideration of the above announcement, however, we solicit all our friends to assist in making the subscription list as much larger as possible. Taking into account the amount expended in obtaining and condensing information, the exclusion of a large most profitable class of advertisements because likely to lead our readers astray, and the low subscription price maintained, we think the *Agriculturist* will be conceded to be the cheapest paper in the country. The truth is, that by publishing so large a number, and having only one office, one set of editors, engravers, printers, stereotypers, etc., for the whole, we are able to give more for the same money, than if the general expenses, aside from printing paper, were divided among a few thousand subscribers only. Every name beyond fifty thousand or so costs only the paper, presswork, and mailing. We again ask our friends to make a special effort this month to add as many names as possible. All the proceeds will go to make a better paper for the whole, and then each will in turn be benefited.

Does it Pay?

Just now, many of the fifty or sixty thousand persons whose term of subscription expires with this month, will perhaps insensibly ask themselves whether it will *pay* to renew for another year. Let us see. The index and reference figures to Volume 23, given in this number, indicate that there have been about *two thousand* separate articles and items. Many of the short items have involved no little care, investigation, and condensation. These with the Calendar, have embraced many thousands of hints and suggestions. Probably no one person has been interested in, or benefited by the half of this; and has not every reader received some hints that are worth more than the subscription price? In estimating, it is proper to consider not only the hints directly and plainly valuable, but also the trains of thought set in motion, and the results indirectly growing out of them. In other words, would any one be willing for a single dollar to blot from his or her mind all the information, and all the thoughts suggested by what has been perused in this journal this year? We think not. We believe that the poorest paper published, if it only sets men to *thinking*, will, in the end be valuable. It is thought and calculation, that make one person's labors more profitable, and more pleasing than those of another. All we can say further is, that the next volume will be no less valuable than the past, and we ask only those to patronize it who, on looking over the whole of the past year, believe that another volume will pay. We will also take it as a favor, if those who think it pays for themselves, will also suggest to their neighbors and friends, that it will pay them to take it.

Cotton Exhibition Postponed.

We have several responses to last month's request, in regard to the proposed exhibition of Northern Grown Cotton; but, few have the required amount, and those who have, prefer, at its present high price, to use what they have in experiments in home manufacture, rather than to prepare and send it to an exhibition in which they are not *sure* of receiving a large premium in competition. Several suggest a postponement of the exhibition to next year, and then have an early, definite announcement as to the conditions of growth, the amount of surface, the cost of production, etc. Under these circumstances, and as only one unconditional offer to exhibit has as yet been received, it would seem to be expedient to postpone the exhibition for this year. In the meantime we hope to hear from those who have experimented the past season, and thus secure at least one object of the proposed exhibition, namely: To learn how far North the plant has succeeded well, and what are the conditions of growing it profitably.

Free Distribution of Seeds.

When possible, we have always announced in the December AGRICULTURIST the list of seeds to be presented to our subscribers for the next year. These seeds have been in part grown specially for the purpose, by ourselves and by others for us, and in part obtained from Europe. But owing to unexpected delay in receiving information from some of our correspondents abroad, and to other causes, we must necessarily delay our seed announcement until next month.

The Premium Maps Discontinued.

All Premium Maps offered have been promptly sent off in every case, except a few of those of the Southern States, which we were disappointed in obtaining, for a time. *All* have now been sent, however. Owing to the advance and scarcity of paper to print them on, they were not only delayed, but the price of all was increased twenty-five per cent beyond what we expected to pay when making the offer. On this account, and from the difficulty experienced in obtaining a supply, we shall send no more after the expiration of the previous offers, which extended to November 30th, with sufficient extra time to very distant persons. When desired, we will procure and send others, when paid, as follows: The map of Virginia, and that of the Southern States, at twenty-five cents each; and the map of the United States, including Canada and New-Brunswick, at fifty cents each.

Postage Stamps still Received—Drafts—Demand Notes.

Many shop-keepers, all the omnibus and railroad lines, and several newspapers, in this city, have announced that postage-stamps will no longer be received as currency. In the present lack of small change, we deem this course detrimental and inconvenient for the public, and so far as we are concerned, shall continue to receive all undefaced, clean postage stamps offered for subscriptions or single copies, where there are fractional parts of a dollar to be paid. For even dollars, bank bills are of course the best.

A draft on a New-York city bank, payable to the order of the Publisher, is the best method of sending large sums. The rates of exchange are now so nearly uniform over the country, that drafts on New-York can be purchased quite cheaply of any Bank or private Banker.

Subscribers on the *Pacific coast*, and in Utah and New-Mexico, can send new postage-stamps of United States Demand-Notes (which are at par here,) or Drafts for large amounts.

American Agriculturist in German.

The AMERICAN AGRICULTURIST is published in both the English and German Languages. Both Editions are of the same size, and contain, as nearly as possible, the same Articles and Illustrations. The German Edition is furnished at the same rates as the English, singly or in clubs. A club may be part English, and part German.

Bound Volumes and Back Numbers can be Supplied.

We shall immediately bind up a number of volumes of this year to supply when wanted. (See terms below.) Those who have a part of Vol. 21, or of any other volume back to XVI., can receive the lacking numbers at a price proportional to the whole year, adding one cent more per number for postage, as this must be prepaid on copies not sent out when issued.

PRICES AT THE OFFICE.

Volumes 16, 17, 18, 19, 20, and 21, *unbound*.....$1.00 each.
Volumes 16, 17, 18, 19, 20, and 21, *bound*.....$1.50 each.

PRICES WHEN SENT POST-PAID BY MAIL.

(*They can not go unpaid.*)

Volumes 16, 17, 18, 19, 20, or 21, *unbound*.....$1.12 each.
Volumes 16, 17, 18, 19, 20, or 21, *bound*.....$2.00 each.

BINDING.—Sets of numbers sent to the office will be bound up neatly in our regular style of binding the *Agriculturist* for 50 cents a volume.

PREPARED COVERS.—Covers for binding, neatly made, with title, etc., gilt upon the back, ready for the insertion of the sheets by any bookbinder, can be furnished for Vols. 13, to 20 inclusive, at 25 cents per cover. *Covers can not go by mail.*

PRIZE FOWLS AT THE EXHIBITION IN LONDON.

(Engraved for the American Agriculturist.)

A few years ago, when the hen-fever was widely prevalent, the above engraving would have created no little excitement. We should have expected visits from fowl fanciers, letters from distant points, and no end of inquiries, as to where specimens and eggs might be procured. Now they will merely be looked upon as curiosities, particularly the Japanese Bantams shown in the foreground. They are indeed singular specimens of the feathered race. Their legs are not more than one or two inches long, and their feathers very curiously frizzled, resembling the style of dressing the hair, in Queen Elizabeth's time. Of the particular value of these fowls for laying and breeding, we have no account. They have not long been introduced to England from their native country. Their tall companions, named the Crevecœur, are also a new importation from the East. In general characteristics they appear to resemble their Shanghai cousins, of which, in their primitive ugliness we have had more than enough. The above engravings are from prize specimens, shown at a recent poultry exhibition in London.

Although many varieties of poultry more curious than useful have been introduced, in consequence of the hen-fever, it has not been without beneficial results. Several breeds of superior excellence, which previously were almost unknown here, are now common, and our native stock has been much improved by various crosses. The extra care, also, bestowed upon favorites for which high prices had been given, was so well repaid by increase in eggs and weight, that others have taken the hint, and it is found profitable to give good care to poultry. It has been proved that with proper attention, a full supply of eggs the year round may be had from comparatively a small number of hens. The particulars of successful poultry raising have so often been noticed in our Calendar and elsewhere, that we need not now repeat them.

For the American Agriculturist.

Keeping Horses in Winter.

The first thing of importance is a good stable, which should be warm, light, dry and well ventilated. Each of these conditions must be observed to insure the health and comfort of the horse. The cold winds must not be permitted to blow upon him, nor damp, foul air fill the stable. Let a plentiful supply of pure air and light be admitted through windows or blinds. The stalls should be 14 feet long and 5½ wide; mangers for hay are preferable to racks, as the horses are less liable to waste their hay by getting it under their feet. The manger should be about 3½ feet high next to the stall, and 6 inches higher in front; about 20 inches wide at the top, 14 at the bottom, and extend to within 16 inches of the floor, which will leave room beneath for the bedding. The top piece on both sides of the manger should be 2 inches thick, of hard wood, to prevent the horse from gnawing. The feed box should be in the right hand end of the manger, and made of two inch hard wood plank; 16 inches square is a good size. The partitions between the stalls should be about 8 feet long, and it is best to have them so high in front that the horses can not get their heads together.

When the horse is idle, two quarts of oats given morning and evening, with plenty of good hay, will keep him in good condition. If corn is fed on the ear, two or three common sized ears will answer the same purpose, or three quarts of corn and cob meal per day. If at light or medium work, four quarts of oats, six ears of corn, or three quarts of corn and cob meal, should be given three times per day, with all the hay he will eat. If at hard labor, six quarts of oats, ten ears of corn, or four quarts of corn and cob meal, will be required. Whole corn is not economical food for horses, as much of it will pass through them undigested; but as it is used by many farmers, I give directions for feeding it. In feeding new corn, care must be taken not to give too much at first, as it is very liable to give horses the colic. Many, perhaps the majority of farm horses, in our part of the

country, are kept upon much less grain than this, but they do not look as we desire our horses should—fat, sleek and comfortable, and *always* ready for service. Carrots are very good for horses, and instead of feeding grain alone, an equal quantity of carrots may be substituted once a day with great benefit. Roots have a tendency to keep the bowels loose, and a horse will thrive better and look much better if carrots can form a portion of his food. An occasional "bran mash" is very good for the same purpose. To make it, scald four to six quarts of shorts, add a little salt, and feed after it has cooled sufficiently. Horses should be watered regularly, at least three times per day; our rule is, water after eating in the morning, before eating at noon, and before eating at night.

[The address of the writer of the above, has been mislaid. It is part of an essay in competition for prizes.—ED.]

From a Farmer in Iowa.

Raising Hogs by Wholesale.

The *Prize Article* on "Raising and Fattening Swine" published in the *American Agriculturist* for August, p. 235, is very good for operating on a small scale. But, as it is here, where from 50 to 1000 head are raised by farmers annually, how can stys be built for them? The lumber and nails for such a purpose can not be afforded. Now I am not advocating feeding hogs in their *wallow*, not by any means, nor letting them lie without shelter. But these things can be provided cheaper than by building stys. The writer of the prize article discards the idea of giving swine any freedom. I have found that in no way can a drove of hogs be advanced so fast through the Summer, (*i.e.*, taking into account the expense, the health of the animals, and the quality of the pork,) as by turning them into a field of rye in the Spring (sowed the Fall before). That will last them until a crop of oats can be grown. Then turn them into that field, or if you please, on a good crop of clover and timothy, in place of the oats. Give them such a lot, with access to plenty of good water, and if you have plenty of corn, a small feed each morning won't hurt them. Let them run thus until October, then shut them up and feed on scalded meal or corn. In this way I venture to say that by Jan. 1st, I'll have a heavier lot of hogs, (with just as good meat) than the man who keeps his pigs in stys, while mine will cost at least 25 per cent. less than his, to say nothing of the *trouble* of feeding through the Summer. I do not speak at random in regard to these things, for I've seen both ways tried. IOWA SUBSCRIBER.

A Comfortable Bed for Animals.

What man or beast does not enjoy it? Every wild animal, from the lordly lion to the insignificant mouse, bestows careful pains upon its nesting place. The universal instinct which prompts this ease, indicates that it is a matter of no small importance in the physical economy. About one-third of an animal's whole life is passed in resting, and nature intended that during this time its condition should be most favorable for restoring and building up the organization. In the care of domestic animals, kept for profit, this point is worthy of special attention. Comfortable bedding directly favors the increase of fat and muscle by helping to retain the animal heat, and also by adding to quiet and comfort. In this way a bundle of straw upon the outside may be equivalent to a feed of grain inside. Horses are usually well cared for in this respect, with a view to keep their muscles in good order, as every tyro must know that sleeping upon a hard board will scarcely give pliancy to the limbs. But good bedding is of little less benefit to cattle. If it be doubted, experiment for two weeks with milch cows; give them comfortable litter the first week, and allow them to lie upon the frozen ground the second, then note the difference recorded in the milk pail; it will be very great.

Straw and refuse hay are generally used, and are well suited for bedding. Cutting into lengths of say six inches, has some advantages, though it would hardly pay if required to be cut by hand. Where these can not be had cheaply, as is often the case in villages, an excellent substitute may be found in leaves. They possess one advantage over straw, in making the very best manure for gardening, when mixed with animal excrements. Spent tan bark, well dried, is another good substitute, also valuable as a mulch. A layer of dried muck, six inches thick, serves a good purpose for bedding. It is a most excellent absorbent, and will remain in good condition for some time without being changed. When well saturated it is just the article for the garden or the field. With proper care in furnishing abundant bedding for stock, a large accession to the manure heap will be made, sufficient of itself to pay for the trouble.

For the American Agriculturist.

Mules Valuable for Farm Work.

If any body wishes the mule for a saddle-beast, he is welcome to his choice, and he will have good company and good examples before him. In Persia, Syria, Spain, Italy, and indeed in nearly all semi-tropical countries, these animals are often used for riding. For rough, mountainous regions, they are invaluable, being so sure-footed. By a little training, too, they can be brought into a very agreeable gait. A foreign writer says: "In Bagdad, most of the learned and holy professions prefer the ass, as do all the ladies. They are of a particular breed, and often brug fifty pounds sterling, ($250). The favorite color is spotless white; they are magnificently caparisoned, and have their nostrils slit, which is said to make them long-winded. Surely, their wind is long enough when they bray! The bray is not much admired, generally, but the author of a scarce tract on the nobleness of the ass, (1595,) after giving us all its sweet notes, concludes by declaring that the continued braying of five or six asses forms a melodious kind of music, 'a song of world without end.'"

But it is with mules, as draft animals, that we have now especially to do. They are sometimes from fourteen to sixteen hands high. They are stronger, surer-footed, and more durable than common horses. They are subject to comparatively few diseases. The expense of shoeing them is slight. They will live and thrive upon one-third less than horses, and eat contentedly the cheapest and coarsest kinds of food. Yet, it is a little remarkable that the ass is quite fastidious about his drink, preferring only perfectly pure water. Hence the meaning of a passage in an ancient classic: "Thersites, would that the fountain of your mind were clear again, that I might water an ass at it."

Much has been said about the obstinacy, stupidity, and viciousness of the mule. But whether these alleged vices are not owing chiefly to the ill-usage he gets, is perhaps an open question. Mules are seldom known to die, or to become old; we never yet met with one called much over ten years of age! At least, their age is seldom thought of in purchasing; for they are serviceable for thirty years or more. We are glad to see that they are being used more and more for farm work. NON EQUUS.

Harness for Oxen.

In reply to an inquiry about harnessing oxen, in the October *American Agriculturist*, I send an account of what I have seen. For more than a generation the people of Selkirk settlement, 500 miles or so Northwest from Saint Paul, have used one-ox carts, the ox being harnessed between shafts, as nearly after the manner of horse harnessing as the shape of the animal will admit. The carts are of very rude construction, no iron entering into their composition, and no lubricator being used, and yet each ox transports a load of 800 pounds from Selkirk settlement to St. Paul, at the rate of 20 miles or more per day. They usually go in long trains, 80 or 100 carts, and the creakiug of the ungreased axles, wood running in wood, can be heard for miles. Within two weeks past there has arrived in Denver, from Council Bluffs, a train of 12 carts on the same plan, but built in the best manner, with thimble-skeins, each cart bringing through 1200 pounds. This is much better than can be done with 4-wheeled wagons, for in that way 4000 is all that three yoke of good cattle can manage.

Colorado Territory. E. K. WOODBURY.

Wintering Bees in a House.

The method of wintering bees practised by Mr. Hogan of Dupage Co., Ill., is thus described in the Prairie Farmer: He builds a house of suitable size to contain his stocks, something like an ice-house, of joists, clapboarding the outside and lining the inside with matched siding, leaving a space of four inches all around. This is filled with chaff (spent tan-bark would do as well), and the hives are ranged four tiers high all around the inside. To ventilate it, he constructs an air tube from the outside under ground to the center of the house, where it is admitted through a perforated board or plate of metal. At the top a passage is made for the heated air to escape. The whole is arranged to exclude every particle of light. The hives are left open as in the Summer. The heat generated by the bees is sufficient to keep the air warm enough for their safety and comfort.

[Some thirty years ago a farmer of our acquaintance in western New-York, built a house very similar to the above, using lath and plaster inside, instead of the double walls. His bees had been prosperous previously, in straw hives set on rude stands, and protected on the back and above with boards. He moved his ninety hives into the new house, and for a short time they did well. But they soon began to rob each other; the moths got in, but they were carefully cleared out several times; the bees gradually died off from some undiscovered cause, and the third year only half a dozen swarms remained alive. These were put back into the old position, where they maintained their own for three years longer, when the whole died out. The high hopes of the farmer of success in bee-keeping were dashed to the ground. He made his bee-house an addition to his dwelling, and until his death always insisted that though fond of queens, bees were too democratic to thrive in a fine house.—ED. *Am. Agriculturist.*]

Experiments with Sorghum — Value of Gypsum.

Friend Harris, in a recent number of the Genesee Farmer, gives a detailed account of some experiments on Sorgium with various artificial manures, from which we condense the main points of interest. The soil, a sandy loam, had been under cultivation without manuring for some thirty years; the last three years it had lain in grass and clover. It was plowed and harrowed into mellow condition, and the sorghum planted June 4th, in hills about 3 feet 4 inches apart. Eleven plots, each containing one twentieth of an acre were experimented upon. The various manures were applied in the hill, being thoroughly worked into the soil, and then covered with fresh earth, on which the seed was planted.

The Sorghum was cut October 7 and 8, and the stalks accurately weighed in the field, with the following results:

No.	Manure used per acre.	No. of Hills.	Weight of Stalks.	Value of Crop per acre.
1	No manure	236	1,947	3,241
2	400 lbs. sulphate of ammonia	123	9,383	15,387
3	400 lbs. superphosphate of lime	184	21,211	23,059
4	400 lbs. superphosphate of lime and 400 lbs. sulphate of ammonia	143	15,097	21,333
5	250 lbs. plaster (sulphate of lime)	184	22,858	34,326
6	2000 lbs. unleached fiard wood ashes	162	15,058	16,120
7	3000 lbs. unleached ashes and 250 lbs. plaster (mixed together)	169	16,165	19,060
8	200 lbs. common salt	161	7,570	9,463
9	400 lbs. sulphate of ammonia, 400 lbs. superphosphate of lime and 2000 lbs. unleached ashes	112	10,528	18,790
10	400 lbs. superphosphate of lime and 2000 lbs. unleached ashes	176	21,269	17,920
11	No manure	171	3,136	3,662

Each plot contained 201 hills, but as the above table shows, many failed. The seed either rotted in the ground or was injured by the manure. The last column shows in the plainest manner the relative yield per acre, allowing the same number of hills to have produced on each plot.

The effect of plaster (gypsum or sulphate of lime) is interesting and instructive. Not only does the plot manured with this, show the greatest yield per hill, but with one exception (plot No. 3) the greatest number of hills germinated and grew. These two plots, No. 3 and 5, were superior to any others, all through the season.

The superphosphate used was a superior article, made from calcined bones expressly for the experiment. It should be understood that the best superphosphate contains at least 50 per cent. of plaster; so that if common plaster contains 80 per cent of sulphate of lime, the 250 lbs. applied to plot No. 5 would contain the same quantity of real plaster as the 400 lbs. of superphosphate applied to plot No. 3; if 90 per cent., it would get 25 lbs. more plaster than plot No. 3.

The plots receiving plaster and superphosphate are the two best of the series. Plot No. 5 is a little the best, and probably received a little more real plaster than plot No. 3. One thing is clear: *the soluble phosphate of lime in the superphosphate* did no good, for on the plot No. 5 we have plaster alone; and on the other plot (No. 3) we have plaster and *soluble phosphate;* and yet the crop is no better from the two together, than from the plaster alone.

In conclusion Mr. Harris frankly says he does not know why the manured plots should produce so much more than the unmanured. It could not be wholly owing to want of sulphate of lime in the soil, for salt, which contains none, more than doubled the crop, and ashes quadrupled the yield. He suggests that it may be due to the plaster accelerating the growth of the young plants, and enabling them to throw out roots and occupy the ground, and thus helping them to get all the food they required. This, however, it must be said, does not appear to fully solve the question, for it does not explain *how* or *why* it accelerates their growth—the great point involved, and desirable to know. Whatever may be the true theory, the experiment indicates that on soils similar to the above, plaster is of undoubted utility; practical men will therefore do well to test it for themselves.

Plowing under Green Rye for Manure.

W. F., of Mercer Co., N. J., has a poor opinion of green rye as a manure for poor soils. He has now a piece of poor land which he would like to improve by plowing under green crops, having no stable or yard manure, but says: "A few years ago I plowed under a good growth of rye in the Spring for corn, but failed to get more than half the yield in corn that I should have looked for without the green crop; the season was favorable for it, but it came up poorly, looked yellow, and grew very slowly, notwithstanding it was well attended. The same Spring another piece of rye was turned under (earlier) for oats. This also failed to give an expected crop. From my experience above given I have had my doubts as to the propriety of plowing under grain crops in quick succession; but as to clover being good, there is no doubt. I have been engaged in the farming business 15 years." [The experience of W. F. is quite different from that of many others, so far as rye is concerned. As a general rule any green crop, plowed under, produces good effects. Clover is undoubtedly one of the best green manures for soils already good enough to yield a growth of clover.—Ed. *American Agriculturist.*]

Bones Good for Manure.

As most of our readers doubtless know, we do not attach great value to mineral manures, as a general rule. That was a beautiful *theory*, at one time so strongly advocated by Liebig and others, viz: that the organic part of plants being composed of the same elements as air and water, the main object of the cultivator should be to supply the inorganic elements, such as are found in the ashes of plants. Hence the importance attached to chemical analyses, to ascertain what are the mineral constituents of the plants or of their ashes. However much may yet grow out of this theory, it is pretty certain that, so far, the application of it has resulted in little practical good.

But without stopping to discuss this matter, we may safely assert that, as a rule, organic materials, (animal and vegetable substances) do act beneficially as fertilizers, and that for the cereal or grain crops, those substances yielding the most nitrogen or ammonia, produce the best results. Animal substances, especially lean flesh and cartilages, abound in nitrogen, and hence these are among the best fertilizers. Bones are made up of cartilage and a mineral part, which is chiefly phosphate of lime with some carbonate of lime. The manure manufacturers claim that the phosphate is the most efficient and most valuable portion of the bones, and that therefore burned bones, or manures made from them, are of great value. We do not now and here discuss that question; nearly all admit that burned bones themselves are valueless, but that dissolving them in sulphuric acid sets the phosphoric acid free, in which state it becomes active. It may be queried whether the good results observed are due to the action of the phosphoric acid as direct food for the plants, or whether the freed phosphoric acid, together with the added sulphuric acid, may not act as absorbents of ammonia from the atmosphere, and in this way produce the same effect as ammoniacal organic manures. It is certain that phosphoric acid has a very ready affinity for ammonia, and on this account it may be a more powerful fertilizer than other acids.

But theories aside, the organic matter, the cartilagineous portion of bones, is a good fertilizer. Trials without number show that bones ground fine, and applied to the soil, stimulate plants to active growth. If ground fine, or dissolved in acid, they become quickly available. When merely crushed, they are a longer time in decomposing, and their full effect is not so soon obtained. For fruit trees and grape vines, where more permanent effects are desired, coarsely broken or whole bones are useful. They decay gradually, and yield a little nutriment from year to year. Unburned bones are far too valuable to be lost. A single bone lying on the surface of the ground where not needed, wastes its substance in the air. Put that one bone at the bottom of a fruit tree or vine, and it will gradually furnish all its valuable elements to increase the crop of fruit. Grind it to powder, or dissolve it in acid to a semi-fluid mass, and apply this to the garden, or to grain or grass, and it will be nearly all used up by the first crop, and show excellent results. We repeat, that bones are of too great value as a fertilizer to be wasted.

Salt in the Manure Heap.

One of the most economical articles about yards and stables is salt. It is just as good to feed to the manure heap as to pigs and cattle. It is best applied in a weak solution in water with a common watering pot. Whether salt does or does not supply direct plant food, it at least prevents the escape of ammonia, the most valuable part of the manure heap. This gas is always leaving animal manure, unless there is plenty of moisture present, or some agent to absorb it. Salt does this without arresting the decomposition of the mass. Sea shore farmers make a large use of sea-weed, without fully understanding the philosophy of its action. It is carted into the styes and barn yards several times in the course of the year, and intimately mixed by means of the plow with the droppings of cattle. Thus all the best parts of the manure are saved by the salt, and a large addition is made to its bulk by the vegetable matter of the sea weed. These weeds gathered from the shore are good manure by themselves, but are still more valuable when decomposed and saturated with manure drippings as they pass through the sty and yard on their way to the plowed field or meadow.

Cocoanut Waste in Gardens, etc.

The fiber of the outer husk of the cocoanut is extensively used in making mats, brushes, etc. In the process of manufacture, a large quantity of refuse is separated from the fiber. A recent number of the London Gardeners' Chronicle says that this substance is now being turned to great account in gardening. It is valuable as a mechanical agent for ameliorating stiff soils, makes an excellent mulching, and forms a good substitute for leaf mold in the finer kinds of compost for potting. Many other uses are named for this material in the garden and hot-house. Though few sources of supply exist in this country, these facts are worth noting by cultivators in the neighborhood of such factories

A SAMPLE PUMPKIN IN 1862.

Novel Exhibition at the Office of the American Agriculturist.

Great Display of Pumpkins, Squashes, Fancy Gourds, etc.

"*That's what we are coming to,*" said our humorous artist, as he threw upon our table the above picture which he had just sketched after examining the large pumpkins exhibited at the Office of the *American Agriculturist* in competition for the prizes offered. He has undoubtedly "stretched things" somewhat, as is his wont, but we believe that no exhibition of the kind ever excited more wonder than has been expressed by the crowd of visitors who have thronged our office during the exhibition. It was a complete success in every respect, in the number and variety of specimens shown, and in the mammoth size of several monsters of the pumpkin tribe.

Two long tables, covering an area of 150 square feet, were crowded with the golden globes, and above these were suspended nearly two hundred specimens of fancy gourds of every variety of form and color, the whole making a display probably never equalled in this country. The ten largest each weighed over one hundred pounds, their aggregate amounting to 1718 lbs., or an average of 171.8 lbs. each! It is a matter of no little gratification, that in this, as in many other friendly contests, we have beaten John Bull, and that too when he had all Europe to back him. Early in the year, the Royal Horticultural Society invited England and the rest of the world, to unite in a great International Show of Fruits, Vegetables, Cereals, and *Gourds*. It was generally understood that the last named productions, including every variety of melon, squash and pumpkin, were to be the chief feature of the exhibition, and we find that contributions from other countries than England were mostly confined to this line. The Show came off during the second week in October, and full reports are given in our foreign files. In variety and number of the gourd family, the exhibition was first class, but according to the figures, Jonathan ranks far ahead in size and productiveness. The heaviest pumpkin shown in London weighed 176 lbs., the second largest 154 lbs. These would look small beside our mammoth specimen, which stands 3 feet high, girts 8 feet 7 inches, and weighed when picked 289 lbs! Its weight has since been reduced by drying out. Four of our specimens each weigh over 200 lbs. So we can now put another feather in the cap of Yankee Doodle, and may claim the fastest yacht, the best reaper, the most effective gunboat, and the BIGGEST PUMPKIN! The cash prizes offered for competition at the *Agriculturist* Exhibition were as follows:

No. 1—For the *Heaviest* Pumpkin or Squash			$20.00
No. 2—For the 2nd	do.	do.	10.00
No. 3—For the 3d	do.	do.	5.00
No. 4—For the Best	do.	do. for cooking	10.00
No. 5—For the 2nd Best	do.	do. do.	5.00
No. 6—For the largest yield on a single Vine			10.00
No. 7—For the 2nd	do.	do.	5.00
No. 8—For the largest and finest collection of Fancy or Ornamental Gourds			10.00
No. 9—For the 2nd	do	do.	5.00

The Exhibition was opened according to previous announcement, on Wednesday Nov. 5th. The following is a list of the entries, in the order in which they were received:

No. 1.—Wm. D. Hall, Wallingford, Conn. Three pumpkins, for the heaviest. Weights 208, 221 and 270 lbs.

No. 2.—By the same, 42 pumpkins, growth of one vine, *the vine with them*; aggregate weight, 1250½ lbs.

No. 3.—J. W. Somarindyck, Lattingtown, L. I. Two pumpkins from one vine. Weights, 221½ and 165½ lbs.

No. 4.—W. R. Renwick, Saugerties, N. Y. One squash, 141½ lbs.

No. 5.—G. M. Van Ness, Pompton Plains, N. J. 6 African Squashes from one vine; 393 lbs. 4 single pumpkins, 67½, 70½, 87 and 85½ lbs., 1 Citron Melon, 37½ lbs.

No. 6.—Rev. Thos. McCauley, Huntington, N. Y. 2 Boston Marrow Squashes (hybrids), 92½ and 112¾ lbs. 1 Apple pie melon, 35¾ lbs.

No. 8.—A. B. Worthington, Middle Haddam, Conn. 1 Pumpkin, 116 lbs.

No. 9.—No name. 1 Pumpkin, 105 lbs.

No. 10.—Richard Wisner, Warwick, N. Y. 1 Pumpkin.

No. 11.—Jas. Devoe, Morrisania, N. Y. 1 Boston Marrow Squash (hybrid).

No. 12.—J. J. H. Gregory, Marblehead, Mass. For quality. Three Hubbard Squashes, Two Boston Marrow, One Turban, one new Hybrid.

No. 13.—N. C. Day, North Leominster, Mass. For quality. Two Hubbard Squashes, 19 and 20 lbs.

No. 14.—Wm. F. Heins, Woodstock, N. Y. Collection of Fancy Gourds, 75 varieties.

No. 15.—B. K. Bliss, Springfield, Mass, collection of Fancy Gourds, 73 varieties.

No. 16.—Master J. C. Williams, West Bloomfield, N. J. Hubbard Squash.

No. 17.—Bliss Coss jr., Branchville, N. J. 2 Hubbard Squashes.

No. 18.—J. B. Bryan, Brooklyn, N.Y. White Egg Gourds.

No. 19.—Henry W. Carey, N. Y. City. Mock Orange Gourds, very large.

No. 20.—John E. Kahns, Keyport, N. J. White Crooknecked Squash.

No. 21.—J. Van Riper, Lodi, N. J. 3 Crooknecked Squashes.

No. 22.—F. A. Leggett, N. Y. City. Boston Marrow Squash, Crooknecked Squash, Round Squash.

No. 23.—George A. Spaulding, So. Woodstock, Conn. One Cream Pumpkin, weight 163 lbs.

The Judges who were appointed by the Fruit Growers' Society, were the following gentlemen: W. S. Carpenter, Horace Greeley, J. Van Brunt, Judge Waterman and S. B. Conover. The pumpkins were carefully weighed under the direction of the Committee, upon platform scales from the well known manufactory of J. L. Brown, N. Y. City. The specimens submitted as "best in quality" were tested by stewing and in pies, cooked at the Home Dining Saloon, corner of William and John-sts., and in several private families.

The following are the awards:

1ST PRIZE: for *Heaviest Pumpkin*, 270½ lbs., (weight at Exhibition.) Wm. D. Hall, Wallingford, Conn., $20.

2ND PRIZE; for *Heavy Pumpkin*, 221½ lbs., to J. W. Somarindyck, Lattingtown, L. I., $10.

3D PRIZE: for *Heavy Pumpkin*, 221 lbs., to Wm. D. Hall, Wallingford, Conn., $5.

4TH PRIZE; for the best Pumpkin or Squash for *cooking*, to N. C. Day, North Leominster, Mass.; variety: Hubbard Squash—$10.

5TH PRIZE; for the second best for *cooking*, to G. M. Van Ness., Pompton Plains, N. J.; variety: "African" Squash—$5.

6TH PRIZE; for largest yield on a single vine, 42 pumpkins, weight 1,250½ lbs. to Wm. D. Hall, $10.

7TH PRIZE; for the second largest yield on a single vine, 429 lbs., to Wm. D. Hall, $5.

8TH PRIZE; for the largest and finest collection of Fancy and Ornamental Gourds—75 varieties, to Wm. F. Heins, Woodstock, N. Y., $10.

9TH PRIZE; for the second best collection of Fancy and Ornamental Gourds—73 varieties, to B. K. Bliss, Springfield, Mass., $5.

HONORABLE MENTION was made of the 4 handsome African Squashes from one vine, weighing 393 lbs., exhibited by G. M. Van Ness, Pompton Plains, N. J.

The object of the Exhibition was not merely to bring out a display which should gratify childish curiosity, but to call attention to the, utility of this production, particularly to exhibit its capacity of yield for stock-feeding purposes, and also to show what results may be obtained by high culture. The contributions of Mr. Hall, particularly, prove that pumpkin vines are not ungrateful for liberal treatment. The following is his account of how he obtained his great yield: The soil was a light sandy loam, that had been for many years a worn out pasture. It was well worked to the depth of *ten inches* and manured with a liberal application of fish guano, composted with soil. Only one vine was allowed to grow in a hill, and ample room was given for its extension. The largest pumpkin, weighing 289 lbs. when first picked, grew at the second set from the root, and was the only one allowed to remain on the vine. On another vine treated in the same manner, only three pumpkins were allowed to grow, which weighed respectively 193, 217 and 237 lbs. Another vine similarly cultivated, but with all the fruit allowed to remain, produced 42 pumpkins weighing when first gathered 1317 lbs. The vine with its laterals, which was sent to the exhibition with its product, measured 1621 feet in length.

It will be seen from the above that while large pumpkins may be easily grown, the practice is not economical. There was a loss of over 600 lbs. of fruit in confining the yield to three specimens on one vine, and over 1000 lbs., where only one was left. Besides this loss, the very

large fruit are worth little except for feeding to stock. It would require almost a regiment of men with good appetites to make way with the pies from one of these mammoths.

☞ Our artist has prepared a beautiful sketch of the finer varieties of fancy and ornamental gourds, which will be presented next month, with some account of that very pleasing department of the exhibition.

"Dakota Potato."

Maj. J. B. Hoffman, of the Ponca Indian Agency in Dakota Territory, proposes the above name for the *Apios tuberosa*, or ground nut, which he is trying to cultivate there. The specimens brought by Maj. H., to the *Agriculturist* Exhibition Tables are of the size of hens' eggs, though the seed planted were but little larger than peanuts. The Indians are fond of them, and it was with some difficulty he secured enough to plant in the Spring, so thoroughly had they been dug for food. They are not injured, but rather improved by leaving in the ground over Winter. The vine producing them is of delicate growth, 3 to 4 feet long and bears pretty clusters of purple flowers. Who knows but here is a plant superior to the far-fetched and very greatly lauded *Dioscorea batatas?* It is at least worthy of trial.

This plant attracted the attention of European savans many years ago. In 1840 Messrs. Eaton & Wright recommended it in their Botany, stating that it was a nutritious vegetable and ought to be enltivated. But our own countrymen seem to have almost entirely overlooked it. We hope Maj. Hoffman will carry out his intended experiments to test its adaptability to general culture as an esculent root, especially in the region where it flonrishes as an indigenous plant, and where the common potato does not grow well. His trial the present year indicates that enltivation has a marked effect upon the size and yield of the root. We will try the specimens presented, in this locality. One of them we boiled with potatoes, and found it required longer cooking. When done it was dry and mealy, somewhat resembling a roasted chestnut in flavor, and not so fine grained as the Dioscorea batatas, though firmer and better.

"Grinding up the Soil"—A Hint.

Any one who has observed and studied the effects of culture upon the soil and growing plants, well knows the great advantage of having the seed-bed pulverized very freely. Suppose for example, we eonld take up the entire surface of a field to a foot in depth and run it through a mill reducing it to a powder. Would not a soil thus prepared for the roots of corn, wheat or other grain, or for potatoes or turnips, be likely to start the seed more rapidly, and produce a far more luxuriant growth, than one merely stirred by the plow and harrow? But this grinding operation is just what is being done by nature dnring every Winter. Lay a lump of soil on a board, wet it, and let it freeze, and it will be found swelled and cracked in thousands of places, and when it thaws will fall into a mass of much finer particles than before the freezing. A second freezing will pulverize it still further, and by continuing the process a few times, the most compact hard-pan soil will be reduced to powder. An open Winter, one in which the soil is many times thawed and frozen, gives excellent preparation for good crops the following Summer, though such weather is bad for the growing of winter crops. The practical hint we would give, is, that cultivators should do what they can to facilitate the pulverization of the soil by freezing. As the ground ordinarily lies, in a compact state, the lower stratum is seldom reached by frost, though this is the portion most needing its effects. Hence the great advantage of plowing it up in Autumn or early Winter. Every acre that can now be stirred so as to let the frost penetrate lower down, will be better ground up. All the lower soil brought to the surface is there much more frequently expanded by alternate cold and heat. Spading or plowing up the garden, leaving it in ridges, is one of the most profitable things that can be done for it now.

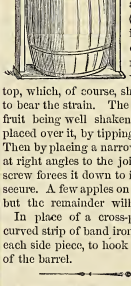
A Barometer Useful in Every Family.

A barometer, good enough for all ordinary purposes, can now be obtained for from $5 to $8. The interest on this sum, even at ten per cent., is only 50 to 80 cents a year. From our own experience and observation, we are certain that the barometer will save many times that amount, to a farmer, and indeed to every person whose business or pleasure depends at all upon being able to predict the state of the weather. It is said that "all signs fail in dry weather," but after several years of careful observation, we can not recall an instance in which our barometer has failed to give indication in advance of any material immediate change in the weather. No matter what the visible signs in the skies, or how threatening the clonds may appear, if our barometer index remains unmoved, we are always confident that neither rain nor wind will speedily disturb the present state of the weather. On the contrary, though the sun may shine ever so brightly and clear, and everything betoken serenity in the atmosphere, yet if the index hand of our Aneroid moves to the left, or if the mercury in our Woodruff commences to sink, we begin to "look out for squalls," and to prepare for them. If the movement be sudden and rapid, we look for an immediate smart shower, or at least a violent gust of wind, but of short duration. If the index-hand, or the mercury, fall very slowly, and continue to decline for a day or two, we are sure that there is an extensive disturbance of the atmosphere, with storms at a distance; that within a day or two these disturbances will reach our own locality; and that it will require several days at least for settled weather to again prevail. Take one example of many: On the morning of September 28, the barometer index began to recede, and thus continued until the evening of the 29th, when the index stopped falling and afterwards rose a little. Yet during both of these days the weather was unusually pleasant. Our barometer was pronounced a false prophet, but we bid the doubters wait a day longer. During the night of the 30th, a heavy rain commenced, and it has not ceased to rain up to this time of writing (noon Oct. 3d), nor will the weather be settled for some time yet. The slow, steady, long continued fall of the barometer is conclusive on this point. There are some exceptions to this rule, depending upon direction of the wind, etc., but these exceptions are readily learned by observation.——On the contrary, we have often known it to be cloudy and threatening, everything indicating a storm; yet the barometer showed no change and there was none in the weather. We are far more governed by the barometer in plans for out-door work, for traveling, etc., than by anything indicated in the clouds or winds. We say unhesitatingly that a barometer is one of the most useful implements on the farm, and in the household. As a guide to cutting, spreading, or gathering hay and grain, such an instrument will often pay for itself in a single day. Farmers who can afford to do so, will do well to secure one now, and study its use so as to be able to turn it to the best practical account during next season.

There are two kinds of barometers. One of these, Kendall's Aneroid, we described in full, in the August *Agriculturist*, 1860. It is neat, compact, readily carried, and every way reliable. See description in our premium list on another page (Premium No. 6). The Mercurial Barometer, having a column of mercury (quicksilver) in a glass tube, is preferred by many, and it is a desirable instrument, though not so well adapted to carrying and hard usage as the spring or Aneroid. Woodruff's patent "Weather Indicator," or Mercurial barometer, is the most convenient Mercurial barometer for transportation of any form we have seen. These cost $5, $8, and $12, according to style, addition of thermometer, etc.

Apparatus for Packing Apples.

In packing apples in barrels for market, they should be pressed together so that no amount of handling and jolting will cause them to move about in the barrel, otherwise they become bruised, and soon decay. Various contrivances for the purpose have been made, and several already published in the *American Agriculturist*.



This plan, which has been in use for some time in Washington Market in this city, is one of the most effective, if not the very best. It is nothing more than a frame of wood or iron, (1½ inch band,) the latter is preferable, large enough to admit a barrel, and having a screw working through the top, which, of course, should be strong enough to bear the strain. The barrel is first filled, the fruit being well shaken down, and the frame placed over it, by tipping it a little on one edge. Then by placing a narrow board across the head at right angles to the joints, a few turns of the screw forces it down to its place, and makes all secure. A few apples on the top will be bruised, but the remainder will be kept from injury.

In place of a cross-piece at the bottom, a curved strip of band iron may be screwed on to each side piece, to hook under the bottom edges of the barrel.

A Novel Mode of Growing Asparagus.

A neighbor of ours has tried the following method for several years, and finds it successful: Laying off his beds four and-a-half feet wide, and sixteen feet long, he spreads on the surface a coat of sand two inches thick, and spades it under. (His soil is a stiff clay.) Then he lays upon this six solid inches by careful measure, of half-rotted dung. After this has settled a week, he spreads over it four inches of good garden soil; and in this he sets out one year old plants, twelve inches apart from crown to crown. The roots soon find their way into the rich provender below, in which they luxuriate, as the large, succulent shoots soon show.

For the American Agriculturist.

A Talk About Troublesome Weeds.

At a late meeting of our Farmers' Club, the subject for discussion, was "*Stoloniferous Plants.*" The gentleman who presented it was a little mistaken as to the exact meaning of the words used. According to Gray and other botanists, a Stolon is "a trailing or reclining branch above ground, which strikes root where it touches the soil, etc.," of which the currant and gooseberry are familiar examples. But in the discussion referred to, it was used in a more general sense, to include all plants (weeds, especially,) which increase by creeping roots, such as Canada thistles, quack grass, and the like.

Speaker No. 1, observed that it was a lamentable fact that the pests of the farm and garden were rapidly increasing. Insects of many kinds swarm upon our trees and vines. Ants are increasingly troublesome, eating up young plants, burrowing in the finest lawns, in the footpaths of the garden, and throwing up unsightly heaps among the choicest flower-borders. In our fields, weeds are spreading in a formidable manner. The white daisy makes many a field as white in June as in Winter; and the mustard-plant makes others yellow as sulphur. The Canada thistle is running unbridled from farm to farm, and quack grass is hard after it.

What shall we do? These weeds exhaust the soil, and they make tillage very laborious. They can be subdued, if we only set about it with a will. Much has been said about cutting down thistles and alders and dock, in a certain month, on a certain day of the month and period of the moon's changes. Little reliance can be put on such rules. If rank-growing plants are cut down when at their full strength, and if the cutting is followed up by a heavy application of salt, either the brine, or the close browsing of cattle in search of the salt, may weaken, and at length kill out the plants; but such results will be the exception, not the general rule. *Grubbing up the roots*, is the only sure remedy.

Speaker No. 2. In my view, the increase of insects is owing mainly to the cutting down of our forests and the killing of the birds. Had we more forest trees about us, multitudes of insects would find homes there, instead of in our orchards and gardens. And if we encouraged the birds to dwell about us more securely, they would help keep down the insects. As to killing out Canada thistles by cutting off the tops, I don't believe a word in it. I have more faith in the old saw that, to make sure work of it, they should be dug up, the roots dried in an oven, smoked in a pipe, and the ashes carefully saved! This plant increases chiefly by an under-ground root. It sends down a perpendicular root, say a foot or eighteen inches long, which then turns off at a right angle, and runs some distance horizontally. From this horizontal root (which is the only *true* root,) there spring up new plants at every few inches. Now, the only sure way to kill the thistle, is to dig up this horizontal root. To cut off the leaves, or to pull up the perpendicular shoot, does not answer the purpose.

No. 3 said, jocosely, that if this thistle has spread into the States from Canada, it is plain that it has strong Southern leanings.

No. 4. In my experience, this plant and quack grass can be kept in check, if not wholly exterminated. The grass is a tough customer, indeed. I once dug up a lot of the roots, laid them on an old stick of timber to dry, but in a few weeks, found that they had penetrated the spongy wood, and looked far from being discouraged! When a field has become infested with these weeds or daisies, my plan is to put it under the plow and harrow. In the Spring, before planting, I plow and harrow twice, gather up the roots of thistle and quack, and burn them. Then I put in some hoed crop, keep the cultivator and hoe moving briskly until the crop completely shades the ground: after this, the weeds will not grow much. After the crop is harvested, I go over the field again, with plow and harrow and rake. The horse-rake answers well to gather the roots into heaps. The year after this, and indeed for several years, the weeds in that field give me but little trouble.

No. 5. I agree with the last speaker, but would add that wherever these pests or others of the family appear, they must never be allowed to go to seed. The scythe should go over the fields and along the roadsides at least twice every Summer. Nor will it suffice for one or two farmers to do this. All should do it, or the careful will suffer from the flying seeds of the careless. I am not so sure that thistles can not be subdued (say in the garden,) by perseveringly cutting off the tops, if they are cut off with the hoe or spade just below the surface of the ground. Like every other plant, they will die if they can't breathe; and their leaves are their lungs. [I have succeeded pretty well in fighting couch-grass in a stiff clay soil, by using a double Michigan plow, and turning under the roots so deep as to smother them. And when the roots rot, they make a capital manure. A neighbor of mine smothers his quack, and plows up his thistles once a month, giving them no rest above ground or beneath it, and they die out from sheer exhaustion.] *

Tim Bunker on Running Astern.

"A great crop of corn this," said Patrick, as he threw the tenth red ear over the heap of stalks from which he was husking.

"Taint nothing to what I've seen over on the Island when I used to live there," said uncle Jotham Sparrowgrass, with a look that would have annihilated anybody but an Irishman.

"An how much d'ye think ye've seen over there, old fellow?" asked Pat., determined to sift matters to the bottom.

"Eighty bushels to the acre of clean shell corn, and nothing used but fish manure neither."

"An sure that was some corn, but the Squire will have a hundred as sure as ye'r born. That is the tenth red ear, and we have not been husking an hour yet, and every red ear marks ten bushels, they say."

"Red ears! you fool!" exclaimed uncle Jotham, the corn is more than quarter red ears. There won't be seventy bushels to the acre on any part of the Squire's farm I know."

"You must go over to neighbor Frink's to see corn," remarked Seth Twiggs, drily, as he sat on his milking stool at the end of the heap, puffing away with his pipe, while his hands were busy with the ears.

"Now Jake, own up," said Tucker, "and tell us whether the crop on that lot was ten bushels and three pecks, or three bushels and ten pecks."

"It was plump twenty bushels, and no thanks to you either," said Jake indignantly. "It is enuff to make any man go astarn to have such a hand to work for him as you are. The weeds grew faster than the corn, a mighty sight."

These remarks were made at a husking bee on my barn floor a few evenings back. I approve of huskings if they are rightly managed, though they probably do more to promote good neighborhood than they do to help on the farmer's work. They make a pleasant gathering of old friends and neighbors, and sometimes relieve a man in a pinch. The scene was a good deal like that in Whittier's song of the huskers:

> "Swung o'er the heaped-up harvest
> From pitchforks in the mow,
> Shone dimly down the lanterns
> On the pleasant scene below;
> The growing pile of husks behind
> The golden ears before,
> And laughing eyes and busy hands,
> And brown cheeks glimmering o'er.
>
> Half hidden in a quiet nook,
> Serene of look and heart,
> Talking their old times over,
> The old men sat apart;
> While up and down the unhusked pile,
> Or nestling in its shade,
> At hide-and-seek with laugh and shout,
> The happy children played."

You see Whittier is an old fellow down in Massachusetts, that writes songs, and once in a while he touches up the farmers as well as the negroes. I suppose it is because he thinks they are both rather sad eases, and need sympathy. Mrs. Bunker says he is the best ballad maker in America, and I believe our Sally is pretty much the same way of thinking. At any rate, I guess he has been to a husking, and knows pretty near how they go on. The old folks that evening had the barn floor pretty much to themselves, the young ones preferring out-of-doors, where they had a plenty of moonshine in the heavens, and I guess some below.

Jake Frink's corn field of course came up for discussion. For I never saw men at a husking but they wanted one more *butt*, than they found in the corn heap. It was certainly the poorest piece of corn in the neighborhood, and if there is any poorer in town, I have not seen it. It wasn't so much because the land was poor naturally, for his farm joins mine, and there can't be a great deal of original difference in the soil. His corn field and mine were not a quarter of a mile apart, but there was a good deal more than that difference in the yield. Tucker probably made an under-statement in putting it at ten bushels and a fraction, but there could not have been over twenty bushels, and one third of that was soft corn. It was hoed only once, and the crop of wild mustard and wormwood was very generous. Grass was so plenty that Jake's cows found the best pasture upon the corn field.

"What is gwine to be the price of mustard this Fall naber Frink?" inquired Seth Twiggs.

"I don't care," said Jake, "I shant have any to sell. It makes tol'able fodder."

"You'll make beef on't I suppose," remarked Tucker very gravely.

"How much profit d'ye spose ye've made on that crop," inquired uncle Jotham.

"Profit!" exclaimed Jake. "I don't farm for profit. I'm thankful enuff if I can get a livin'. I've allers had a hard time on't, and this year have run astarn a little more than common."

"And where do you 'spose the leak is, in your pocket?" I inquired. "Wall neow I can't tell," said Jake scratching his head. It seems as if the trouble was at the top of the pocket instead of the bottom, and I've been allers siferin' to find out why money didn't git into my pocket. Mine allers gits out afore it gits in, so that the most of the time I don't have nothin'. I've allers been runnin' astarn since I begun to farm it, and I don't know what the matter is."

Jake's puzzle is that of a good many others, though few, it is to be hoped, are quite so bad off as he is. They do not make any headway, but are rather getting in debt every year. Many

have to sell out and change their business, or emigrate to the west, where the land has not been so long abused as it has in the older States. There is some thing in Jake's insinuation that bad help is the cause of bad crops. This is apt to be the case where the employer is not in the field himself with his hands for a large part of the time. I have never yet seen a farm that would thrive without the constant oversight of the owner. Farming necessarily confines a man at home as closely as any other business. There are occasions of loss every day in seed time and harvest, if he is away from home. But Jake's trouble is not here, for he does not hire much help of any kind, and what he does hire is a fair average of farm help.

One thing that makes him run astern is the want of all system in making manure. He does not feel that this is an essential part of a farmer's business. He does not make one load where he has the material to make ten. An empty barn-yard makes a barren corn field. This makes a man discouraged, and he does nothing promptly and with a will. He runs astern in every crop through the season, and in his pecuniary affairs at the end of the year.

But this is not all the trouble with my neighbor. Jake is not what he ought to be morally, and this perhaps lies at the bottom of his poor farming, as is the case with a multitude of others. It takes something more than a strong body and a sound mind to make a successful tiller of the soil. Manhood is as much an element of prosperity in this as in any other calling. If a man goes to the village and haunts taverns, nothing will save his business from disaster. He will make foolish bargains, sell what he ought to keep, and buy what he does not want. If he is tricky in his business dealings, he will soon lose the confidence of his fellow men, and the market for his produce. Temperance and integrity are about the best stock a man can keep on the farm, and with these, I have rarely known a farmer to run astern.

Hookertown, Nov. 15th, 1862. Yours to command, TIMOTHY BUNKER, Esq.

Notes from Colorado.

Mr. E. K. Woodbury sends the following items to the *American Agriculturist*: The place from which I write (La Porte), lies at the foot of the Rocky Mountains, in about latitude 40° 30', where a small, clear, rapid stream called *Cache la Poudre creek* issues from the mountains. At this point the Cherokee trail, to which the overland mail route has recently been changed from the South Pass, leaves the plains for scenery as famous for variety as is that of the plains for monotony.

But little of the land in this region is adapted to agriculture, and this requires irrigation, for which the rapid current of the streams furnish excellent facilities. Still we begin to produce fair crops of cereals, while all sorts of root and vine crops thrive most luxuriantly. What *tame* fruit will do we can not yet tell, but we have delicious wild strawberries, raspberries and gooseberries, currants, plums and cherries, and two kinds of cactus that yield palatable fruit as well as beautiful flowers. We are not backward in efforts to supply ourselves with apples, peaches, and grapes, and in regard to the first and last, we feel quite confident of success, less so in regard to apples, though all three (planted and set out this Spring) look promising. There is one item on which we shall eclipse you utterly. A Yankee or a Kentucky grazier who should look at his beautiful pastures, every inch covered with luxuriant verdure, would laugh at our sandy plains, not half covered with grass, and the little there is, so short as hardly to give a hold to bite it by; but he would be wrong after all. Within five years, unless the home demand uses all our beef, Colorado will sell cattle in Gotham. From this stream, and I don't know how much further north, down to, or rather up (South) to the Arkansas, the foot-hills of these Rocky Mountains and the adjacent plains, probably furnish the best pasturage on the Continent. Even in this latitude cattle do not require feeding more than three *weeks* during the year, and a majority of the cattle and ponies that are not worked, do not get a bite of hay or grain during the year. E. K. WOODBURY.

Agriculture of the Aborigines.

Little can be said of it, for it did not amount to much. Their principal crop was corn, called by them *menchin*. It was of several sorts, red, white, yellow, blue, black, speckled, etc., though the white and yellow were the most common. At the far north, they had a kind that they called *mohaust's* corn, which, though planted in June, ripened before frost. When the natives had occupied a piece of ground for several years, they manured it, using at planting, three fishes to the hill. The favorite fish for this purpose was a kind called *aloofes*. The early white inhabitants of New-England followed the example, and found it to their benefit.

After the whites came to this country, the Indians (the Indian *women*, be it known,) began to plant pumpkins, squashes, beans and turnips. Not very wisely, they used the hills of corn for bean-poles. Of the dried cornstalks, they made fodder in Winter: they also wove the husks into mats and baskets. Pop-corn was a favorite dish with them; the popping being done in hot ashes. Some of the corn thus roasted was eaten as Yankees eat it; much of it was pounded fine in stone mortars, and then made into pudding or bread. They also raised "sweet corn," which they ate as we do; they likewise boiled and dried and stored away a good deal in bags for Winter use. They, however, depended very much on the husbandry of their bows, traps, and fishing-rods.

Keep away from New-York.

A young man writes to the *American Agriculturist*, from Bergen Co., N. J., as follows: "I have a few hundred dollars with which I am thinking of starting some business in New-York City. A friend advises me to stay on my father's farm, and go into the business of raising poultry for market; which do you advise?" Similar inquiries are addressed to the Editor, almost weekly, from all parts of the Union. To all such we give the general answer: By all means keep away from this or any large city. Better raise poultry, pigs, pears, or any other produce, that would afford even a moderate income, than swell the number of anxious, careworn, and in most cases disappointed men who are struggling against the tide of competition which makes success in a large city the rare exception. Not more than one out of every hundred engaged in business here, grows rich; while at least eighty die poor. A larger number grow rich by farming, and not twenty, probably not ten, per cent. of those engaged in agricultural pursuits are ever reduced to poverty. This is the money view of the case. Moral statistics would show a yet more fearful risk to be encountered by changing a country for a city residence. We consider the chances of "doing better" by removal to the city about equal to the chances of safety in springing upon a locomotive in full motion: one man in a thousand may do it unharmed and be carried swiftly to the end of the route; the multitude would be quickly crushed. Sane men would choose the safer way of jogging over the ordinary highway with a steady team, or on foot.

Rustic Work, in Fine Country Seats.

Every one knows that it is very pleasant to meet with rustic arbors, seats and grottos in the retired parts of fine country places. Has any one ever stopped to consider *why* we enjoy such scenes? A traveler, in his description of the elegant grounds of Woburn Abbey, hits very near it. He says: "There are a number of ornamental cottages scattered around the margin of Woburn Park, of much exterior taste, and adorned by rustic work of various kinds. In some of them is an apartment for the reception of small parties from the Abbey, who wish to amuse themselves by allusions to primitive simplicity; for it is one of the enjoyments of those who are habituated to live in a style of high art and refinement, to take occasional refuge in the *contrast produced by comparative artlessness and simplicity*." That is it—the love of contrast.

Farmers Produce Wealth.

We are not disposed to underrate the importance of other callings, but in the actual production of commodities, the farmer confessedly ranks highest. He comes the nearest to being a creator of wealth.

Compare, for a moment, the nature and results of other pursuits with those of the husbandman. Take the manufacturer. He does but change the form of materials already produced to his hand. He adds, indeed, to their utility, or beauty or convenience, and in so doing is a public benefactor, but he is less a creator of values than the farmer. The miner does but bring up the crude ores already lying in the bowels of the earth; he does not create iron, lead, gold and silver. Yet let him receive his just reward. The man of commerce produces nothing, adds nothing to the world's wealth that did not exist before. He is simply a medium for the exchange of commodities. The commerce may be between individuals or nations, yet the result is the same; it is only a barter of equivalents—an exchange of six for half a dozen.

Something more than this can be affirmed of agriculture. It positively adds something to the stock of commodities. The crops gathered from a thousand hills were not here last Spring; the nation is positively richer by so much. Or rather, what remains over, after the cost of production is taken out, is so much added to the common stock of wealth. Yet, let not the farmer put on any unseemly airs. He could accomplish little without the aid and sympathy of other callings, and his products would be of little value without them. The eye can not say to the hand, I have no need of thee. Each fraternity of laborers is the friend and patron of the other; their interests are common. Let them hold each other in high esteem.

People usually consider two hands enough for all purposes, but we recently saw a man on Nassau street, who had *got a little behind hand*.

PROFITABLE WORK FOR WINTER.

Gather a Supply of Fuel Early.

The above scene will be realized on thousands of well regulated farms, at the first fall of snow sufficient for good sledding. The early gathering of a supply of fuel for the year has so many advantages, that to neglect it indicates bad management. If left until late in the Winter, much fuel that might be turned to good account may be buried under the snow, and accumulating drifts often make the woods almost inaccessible, or greatly increase the labor of collecting and hauling. By having a large supply of fuel at the door early in the season, profitable work is provided for many stormy days, in cutting and piling it under cover, which might otherwise be unemployed or wasted at the store or tavern. One of the secrets of successful farming is to so arrange the work that no hour need be without its task; another is that no operation shall be allowed to encroach on the time needed for something else. Both these points are gained by preparing the year's firewood early in the season. As we stated in the *Agriculturist* Calendar for November, it takes the heat of almost one half of green or soggy wood to burn the other half. Water, in changing to vapor, absorbs and conceals a thousand degrees of heat. A cord of charcoal gives out more heat in burning, than a cord of wood. A cord of thoroughly dried wood loses a thousand times less heat in the smoky vapor, than if burned when green. Therefore, get the Winter's fuel to drying out, under cover, as soon as possible. It will save fuel, time, vexation, and health, and be of great benefit to the housewife.

In most of the settled sections of our country, forests have been so reduced in extent, that it is an object to preserve and encourage their growth. In many places it is a question worthy of consideration whether it will not be more profitable to substitute coal for wood, and allow the forests to grow. Young trees increase rapidly in size, without any care, and the year's growth on an acre will usually pay a large percentage. At any rate, a little management will aid in economizing the limited supply. By cutting out only full grown trees, or those partially decayed, and thus making room for those of thrifty growth, the year's fuel may often be subtracted with positive advantage to the forest.

The Arboretum at Chatsworth.

A contributor to the *American Agriculturist* writes: Few readers need be told that an arboretum is a collection, into one place, of a large number of trees of different orders, species, and varieties, and arranged, more or less, in a scientific manner. They may indeed be distributed on principles of taste, rather than of obvious science. This has been undertaken in several small collections in this country, as likewise in the fine arboretum at Chiswick, England. And this plan is one that we should like to see followed in planting the grounds of our Colleges, and other large institutions. If no duplicates of either trees or shrubs are employed, a large variety can be got into a few acres. We have been shown a plan for embellishing a private country-place, of only about an acre in extent, drawn up by a scientific landscape gardener, in which upwards of one hundred species of trees and shrubs were noted down for planting. Such a mode of adorning a country home, must give it a peculiar interest.

But for large grounds, as from five to twenty acres, the first-named plan is doubtless best: certainly, it is the most scientific. And if the work is well done, it can be made to furnish at once an arboretum and a delightful pleasure ground. The famous arboretum at Chatsworth, England, is of this sort. It embraces, we believe, some forty or more acres, and contains upwards of two thousand species and varieties of trees. The trees, shrubs and plants are set along the margin or within near view of a carriage road which winds through the premises. They are all set far enough asunder to allow of their full development, and to admit of the subsequent introduction of other newly discovered species or varieties. They are classified in families; and it is very interesting to study out the relationship, where the external resemblance is often very slight. The road which rambles through so many trees is about a mile long. The name of every tree and plant is marked on a wooden label, and the letters are so large and distinctly painted, as to be read at ten yards' distance. Each tree is marked with its scientific name, its common English name, its native country, the year of its introduction, and the light which it attains at maturity.

All these trees and shrubs, it should be remembered, are those only which are hardy in Great Britain; of course, then, many interesting species have to be left out. It is an interesting fact that this vast collection of rare vegetation has not cost the owner of the property, the Duke of Devonshire, a sixpence. The ground has been prepared, the trees bought, and all other expenses paid from the proceeds of the timber trees with which the domain was originally covered, and which were removed and sold only just as fast as the room was wanted for planting. This fact indicates either that this timber was of remarkable quality, or that the price of timber is vastly higher around Chatsworth than any where in our own country.

As this public ground is centrally situated, and is generously thrown open to all visitors, its influence must be salutary and wide-spread.

Many a person receives here the first germs of a taste for rural pursuits. Many a person is surprised to learn of the wide variety of trees and plants which have been brought into cultivation. It is said that the day seldom passes when botanists, or amateurs, or nurserymen may not be seen here, examining the trees and making notes in their memorandum-books, for use elsewhere. As Mr. Downing said, when visiting it, in 1850, "The most perfect novice in trees can thus, by walking round the arboretum, obtain in a short time much knowledge of the hardy Sylva; while the arboriculturist can solve many a knotty point, by looking at the trees and plants, which no amount of study, without the living specimen, would settle."

We are happy to know that some of our leading nurserymen, in this country, are establishing arboretums of considerable extent, where the purchaser can see trees and shrubs in their maturity and perfection. And some of our literary institutions and country-residences are being embellished in the same way. A good idea.

For the American Agriculturist.

Secure the Best Varieties of Apples.

Farmers and orchardists who have more apple trees than is necessary to supply their families with an abundance the year round, will do well to change the varieties of the surplus trees by grafting, to Sweet Bough, Golden Sweet, Jersey Sweet and Tallman Sweet for stock, and to none but the very best long keeping varieties for market. When there is an abundant crop as at present, the Fall and early Winter market is seldom remunerative, but long keepers like the Northern Spy, Esopus Spitzenberg, Roxbury Russet and Baldwin, will always pay if properly managed and kept for late Spring market, especially the Spy and Russet. The Northern Spy is a large, handsome, showy apple, of good quality, a very long keeper, and retains its freshness longer and commands a higher price than any other apple of its season. It is not generally known and appreciated, or it would be more generally cultivated both for family use and market. Some parties have charged it with being a shy bearer, but this is an error, and results from the fact that being a thrifty, vigorous grower while young, it does not come into full bearing as early as some varieties which are moderate or slow growers while young. Any man who plants an orchard of this variety and trains (prunes) and cultivates according to its peculiar habits, can make no better investment, and neither himself nor his posterity will ever regret this choice. It is a sound, healthy, long lived tree, uniform in size and form, and the handsomest tree grown.

On account of its rigid, compact and uniformly upright habits it may be planted 25 feet apart where those of larger growth and spreading habits, like the Swaar, Baldwin and Fall Pippin, planted on the same soil, would require at least 30 feet distance apart. Furthermore, the Spy should be grown in the nursery with very low heads, commencing with two to four branches not more than 2½ feet from the ground, and those branches cut back to one foot, and the branches of the next season's growth to 12 or 15 inches, and so on, keeping the center open to form as broad a head as possible. This mode of training will improve the natural upright form of the head and also hasten its bearing.

Another fact which highly recommends the Spy is, that it blossoms two weeks later than others, which would often save the fruit from destruction by late frosts like that of the Spring of 1859, and this peculiarity makes this adapted to northern localities where Spring frosts are late and severe, as in a portion of New-England, Canada, St. Johns, and New-Brunswick. POMOLOGIST.

Business Hints to Nurserymen.

Let us say that, in what follows, we are not soliciting advertisements for this or any other journal. *We* can not afford to do much advertising: paper is too costly; postage would be doubled if we added a single page more; and, as a rule, a page of good reading matter set before at least two hundred thousand readers (not all subscribers, of course,) in the end pays better than even our high prices for advertisements.*

First then, we say, that large advertising, judiciously done, by good reliable nurserymen, is a paying operation. It costs little more to provide and sell $13,000 worth of trees and plants than it does for $10,000 worth in a year. The same organized force of men, the same machinery, etc., is required in one case as in the other. As with newspapers, so with nurseries, the cost of offices, making out catalogues, and keeping up a working force, is almost as heavy for a small business well done, as for a large one, and the largest profits are on the last sales. A few hundred dollars in advertising will pretty surely bring the increased trade.

Second. In making out catalogues, advertisements, hand-bills, etc., it is best to be explicit. Tell just what is for sale, the kind and character of trees and plants, the price of each; what is to be charged for packing—in short, answer just such questions as are likely to be asked in a personal conversation. A man is much more likely to buy, and to want to buy a thing, if he knows just what and how he can buy, than if the particulars are left in uncertainty, and he is in doubt about the "extras."

Third. The best season for advertising most largely is, we think, in Winter. People then have time to read, to plan, and select what they desire. A man will be much more likely to decide upon setting out an orchard, or ornamental trees, while he has leisure to look over the subject, and calculate the advantages, than when spring work is beginning to drive him up. Ten to one he will then put off tree-planting to a more convenient season. Suppose that all the trees to be purchased next Spring were selected and ordered in January and February, with all the preliminary correspondence completed before April. The purchasers would then be on the look out for manure, for the preparation of the ground, and be much more likely to make the trees live and thrive—to the credit of the seller. On the other hand, the nurseryman would have his plans all laid, and be able to have the trees taken up at the right time, packed in good order, and not hurriedly and imperfectly; his work would be done more profitably and more satisfactorily all round. As it now is, late in the Spring the nurseryman advertises, people get up a furore for trees, their orders are rushed in, the sellers run short on particular sorts, and have not time to correspond with those ordering; the arrival of large orders at once creates confusion and hurry; trees are hurriedly packed and sent off; the buyers plant them hurriedly without due care, and the results are—well known. We esteem the honest, intelligent nurseryman, who sets forth an attractive display of really good trees, and induces people to buy them, as a benefactor to the country, for there are not a tithe of the fruit and ornamental trees in the country that there ought to be, for the profit and pleasure of the people at large. The past season was an exception; the product of fruit was greater than ever before, and greater by far than we can expect as a rule; yet, except in a few favored localities, not half of the people have been supplied with an abundance of good fruit during the present year.

One hint more. Nurserymen are generally too ambitious to get large catalogues, embracing the greatest possible variety of every kind of fruit. They must offer two or three hundred varieties of apples and pears, and a proportionally large variety of other fruits. It is all very well for two or three great central establishments to have and offer about every thing grown; but there are in reality only a few kinds of the different fruits that are worth buying. If we were about starting a nursery in any locality, looking to our own profit, and the interests of our customers as well, we would carefully ascertain what were a *few* of the *best* apples, pears, peaches, plums, etc., for the localities where we looked for trade, and push these into the market. To induce a man to purchase an assortment of thirty or forty kinds of apples, for example, might tickle his fancy, and our own pocket, but it would neither be to his benefit, nor to our lasting credit.

Finally, no man should touch the nursery business, unless he have experience and observation among trees; nor unless he intend to make it a permanent business, so that he will feel it to be his *interest* to acquire and sustain a credit for strict honesty. The meanest of all cheating is that in which a man palms off a poor or untrue fruit tree for the sake of a shilling profit, involving the buyer in loss of purchase money, loss of time and care, and loss of interest, when after half a dozen or a dozen years of expectation, he finds that he has been the victim of deception.

* We say high prices, because some think our charges high, though in reality $1.50 a line would be cheaper than 10 cents a line in the average of journals of a similar class. The true method of estimating advertisements is: *first*, the price per line for each 100 or 1000 readers reached; *second*, the character of the readers; *third*, the smallness of the pages and their moderate limit and number, and the consequent likelihood of any advertisement being seen; and *fourth*, the select character of the advertisements. On these points we leave the *Agriculturist* advertising pages to speak for themselves, with the single remark that we reject a far larger number of advertisements than we admit.

A Common Mistake in Planting.

One of the greatest and commonest errors in tree-planting, is that of setting out large trees and many of them, in small inclosures. The rural improver thinks that he wants a great variety of trees, such as he has seen on Mr. Smith's place, and at Judge Jones' great establishment. So he adds tree to tree, year after year. While they are small, they look pretty, and all goes on well. But ere long, they spread out their limbs on every side, until they meet and overlap each other, making a complete forest jungle. None of them can become well-formed trees; they grow up spindling, or lop-sided, and give little real satisfaction. And besides, what can be expected of the grass under such overhanging boughs and such a mass of tree-roots? And what of shrubs and plants? Where, too, are the views of the street, or of the surrounding country? Everyway, the practice is a bad one.

Here let a remedy be suggested: Set out but few trees. Plant the largest along the bounda-

ries, and the smaller around the dwelling. Set them so as to preserve views of the neighborhood, at the best out-looks. Calculate for their growth many years ahead, and plant accordingly. Many persons plant a large number of trees in their grounds, intending, at some future day, when the trees become crowded, to thin them out. But very few persons have resolution enough to cut down a tree which has become large and thrifty, especially if it was planted by themselves. Multitudes of persons annually impose on themselves, and multitudes of places are annually ruined in this way.

It is safer, perhaps, for amateurs who make trees their habitual study, to have a large variety of trees, and of all sizes. They will take care of them; and when one interferes with the healthy growth of another, it will be removed. But for most persons, the better way is to select a few hardy, free-growing trees, set them at wide distances apart—say at least thirty to forty feet—and let them grow at their leisure. The effect will be good, and increasingly pleasant for a life-time.

Trees Against Flowers.—A Debate.

(Overheard and Reported for the American Agriculturist.)

John—Well, Mary, what do you think of flowers, this cold day? I reckon your posy-beds are done with for this season.

Mary—No, indeed. I have a fine collection of them here on the plant-stand. Flowers are not confined to the Summer season. See! I have chrysanthemums, geraniums, fuchsias, heliotropes, petunias, etc., making this southern window all a-glow.

John—Yes, that's better than nothing. But look out of doors. Where are the ten thousand summer flowers which filled the garden, and bloomed on hill and dale? All dead, or frozen stiff and buried up with snow. But my favorites, the trees, are still alive and doing well. The deciduous trees have cast their leaves, but their limbs and feathery spray are still beautiful; and the evergreens have undying charms.

Mary—I can't bear to hear you disparage my pets. Think how early in the season the spring flowers appear. The crocus, and snow-drop, and violet, hardly wait for the snow to melt. Go out even now, and brush off the snow, and you'll find the Christmas rose in bloom. Flowers begin early to blossom, and they persevere in doing so until Winter returns.

John—But, dear lady, only think of the trouble they make for mankind. One has to dig and manure, and rake and weed, sow seeds and save seeds, thin out and transplant, prune and tie up, and water, and protect from sun and frost, and so on—an everlasting botheration. Now, when I set out an apple tree or an elm tree, and get it once established in good soil, there's an end of all trouble. I can now stand or sit and look at my beauty, and enjoy it. All I have to do henceforth, is to clip a stray limb here and there, and it will go on, year after year, and build itself up—a splendid piece of architecture.

Mary—Good! sir, you *are* eloquent. But think what a *variety* of beautiful things we have in flowers—variety in color, shade and tint, form and fragrance. And then, what endless combinations we can make of these, both in the garden and in bouquets. How many pleasing associations florists have, poetical and historical. These touch the heart, and weave about our finer sentiments in a way that trees can not.

John—And *you* are eloquent. But hear one word more, before I submit to your superior arguments. You go into ecstasy, every Spring, over your beds of hyacinths and tulips; but remember, that in a very few weeks, these beds become a sightless mass of dry, withered stalks. A maple, or pear tree, or magnolia, blossoms, but the flowers are succeeded by a harvest of bright-colored and useful fruit, and by clustering boughs of fresh, green foliage. Bear in mind this fact, also: when you set out a dahlia, verbena, or other flowering plant, in the Spring, it attains its perfection in a single season, and that's the upshot of it. It dies down when the first frost comes, and each succeeding Spring you have to begin where you did the Spring before. You make no progress from year to year, and would gain nothing more at the end of a lifetime. But in setting out a tree, you plant something which is a pleasant object from the very first, and which develops itself more and more every year; it is something larger and grander, every season, and will continue to make progress for one's whole lifetime.

Mary—My dear friend, there's something to be said on both sides. Trees give us refreshing shade; they suggest ideas of repose and comfort.

John—They give us fire-wood and lumber, and ship-masts, wagon-hubs and ox-yokes.

Mary—Yes, you practical man. The oaks of Mamre, the cedars of Lebanon, "the pine-tree, and fir-tree, and box-tree, together," have sacred associations, as well as the rose of Sharon and lily of the valley. I think we had better shake hands, and agree that flowers and trees are both good things in their way, and were made for man's use and enjoyment.

[Our reporter goes on to tell how John and Mary compromised, and agreed that each was right in his and her tastes; and how John fell to praising the rose bloom on Mary's lips, and—but the reader may guess the rest. They are likely to have both trees and flowers, and enjoy them *together*.—*Ed. American Agriculturist.*]

For the American Agriculturist.

More Standard Fruit Wanted.

As the season for selecting sions for propagation is at hand, I would suggest to nurserymen the importance of materially reducing their long lists of varieties, and propagating none but the best. It costs no more and is as easy and convenient to grow them, as inferior sorts. When trees are grown, no matter how poor the variety, they are almost sure to be sold by some unscrupulous agent or tree peddler. If a man wants one or two thousand trees of one leading variety, he can not obtain them without purchasing a greater number of assorted kinds, which he does not want, and should not plant at any price, and if he selects but one or two leading varieties, he must pay from fifty to one hundred per-cent. more for them. The same difficulty occurs in selecting pear trees, which would not be the case if nurserymen were generally more scrupulous in discarding all inferior and worthless sorts. Pomologist.

Experience in Peach Culture.

To the Editor of the American Agriculturist:

During a long experience in raising peaches I have tried many experiments and have found the following treatment most beneficial: I sift coal ashes around the trunk of each tree to the distance of two feet, and five or six inches deep. The trunks are washed with whale-oil soap twice a year, using a quarter of a pound of soap to a gallon of water. I apply very little manure. About the 15th of April, 1st of June and September, and the middle of November, the trees are carefully examined for worms, which are cut out and destroyed. I have a Morris White tree which has been treated in this manner, and has borne a good crop for eleven successive years, and it promises to last a long time, with proper care. Northumberland Co., Pa.

Wine and Grape Fair in Hermann—Notes on Grapes in Missouri.

A correspondent, F. A. N., sends the following notes to the *American Agriculturist*: This little town of Hermann, in Gasconade County, about 80 miles west of St. Louis, situated on the Missouri river and the Pacific Railroad, is probably the only place in this State which will have held a fair this year. Out of a population of scarcely 2,000, men, women and children, so many have enlisted in our armies, that not a sufficient number of citizens liable to military duty to form a militia company have remained. As a natural consequence, the vineyards have been neglected in most cases, in some worked only by women and children, and in some not worked at all, though vine-growing is the principal and most lucrative occupation in this part of the county. In view of these sad times it was thought hardly advisable to venture on holding a fair; yet the hopeful spirit of our people predominated, and they at last, on short notice, exhibited under the auspices of the Gasconade County Agricultural Society the produce of farms and vineyards.

The main features of the exhibition were, the exceedingly fine display of grapes on boughs, in bunches, and as wines. There were, in all, some 35 varieties of grapes, grown here out doors, the most attractive of which were boughs of the Herbemont, Concord, Norton's Virginia Seedling, Catawba, North Carolina Seedling, and Cunningham. One bough of Norton's Virginia Seedling with 81 fine bunches was the most prolific on exhibition. In this region all the vines are grown on the renewal or spur-system, allowing each strong vine to have two shoots of about 6 feet length.

I have taken some pains to collect the observations and experiences of our most successful vine-growers as to the relative value of the different varieties raised here, and will give a short synopsis of my notes, which I derived chiefly from the brothers Poeschel—the successful competitors this year. The following statements are, therefore, not my individual opinions, but the result of observations by intelligent cultivators.

One circumstance in this connection deserves special mentioning—the most successful because most observing and discriminating vine growers, were not brought up as such, but commenced after they had settled here in their maturer years.

Market Grapes.—*Concord*, dark colored, showy, large, fine flavor, early, prolific bearer, quite hardy, very easily propagated.—*Union Village*, very showy, hardy, healthy.—*North Carolina Seedling*, a very valuable, showy market grape, sweet, resembles Isabella, prolific bearer, a week earlier than Concord.—*Delaware*, white or light colored, hardy, healthy, very sweet, prolific; fine bunches, berries medium.—*Allen's Hybrid*, superior to the Delaware; may rot some; will be further tested.—*Rebecca*, very fine, pretty good bearer.—*Anna*, healthy, fine.—*Cassady*, promising; to be tested further.

Wine-grapes.—*Herbemont*, though small berry, the cluster is so crowded that there is no room

for an additional berry, except at the ends of the bunches; bunches very large, heavy; very thin and delicate skin; no pulp, all juice; of the most delicious vinous flavor; two small seeds; healthy, good bearer, must be heeled in through Winter; is being propagated in preference to older varieties. Wine, all that can be desired. Ten pounds of grapes are reckoned to yield one gallon *must* at the first pressing.

Cunningham, similar to the Herbemont.

Concord, but little wine yet made of it, but that little is of an excellent, fiery character.

Norton's Virginia Seedling, healthy, extremely hardy, somewhat difficult to propagate from *cuttings* (better from layers), berries small, but crowded in the bunches; very prolific. Its wine is decidedly superior to any other red wine, whether native or foreign, and is a better keeper than the imported clarets.

Delaware makes a good strong wine, when used alone, and when mixed with other varieties.

Catawba, I put this old variety last, because it has lost many of its former friends by its being capriciously inclined to rot; it is sometimes too late in ripening, loses its foliage just when it ought to keep it, and is withal not quite hardy. Some years it behaves very well, yields an enormous crop of first quality (300 gallons *must* from one acre, worth this year $355), averaging 50 fine bunches to a healthy vine. The best vineyards I have seen this year were Catawbas, wholly or for the greater part; and the worst were Catawba also. But plenty of elbow-grease, with bucketfuls of perspiration and a generous supply of well rotten compost were at the bottom of the thrifty, luxuriant vines.

Isabella is either torn up, or, when a strong root, grafted with Concord. Itself is not worth the room it occupies. Soil and climate will not agree with this favorite of the East.

There are quite a number of other varieties which have been tested here for several years, and some (*e. g.*, Hartford, Clinton, To Kalon,) will maintain a place in public favor; others will be grown only for the sake of having them.

For the American Agriculturist.

It Pays to Lay Down all Grape Vines.

It is now generally conceded by the most successful fruit growers, that it pays well to lay down even the hardy vines, like the Catawba and Isabella. It is not necessary always to cover them with the soil, though this is sometimes the most convenient substance. I am now, in October, reaping the benefits of this precaution, in the shape of the finest bunches of Isabellas I ever raised. Not only are the bunches large, but the berries are of unusual size, and of the finest quality, so that grapes under glass are hardly coveted. The vine is trained partly upon the southeast end of the house, and partly upon the southwest, and is now twelve years old. The part upon the southeast, which has the best exposure, was left upon the trellis; that upon the southwest was laid down upon the flower border which runs along the side of the dwelling, and was covered slightly with sea-weed, coarse litter, and manure, last December, after trimming. It was raised and fastened to its supports about the middle of April. Both sides were summer pruned, and sprinkled with sulphur once. There was a fair crop upon the southeast side, but nothing to be compared to the grapes upon the other. With a little of the skill of Drs. Grant and Underhill, people who live along the Sound need not send to Croton Point and Iona Island for their grapes. The Isabella and the Catawba both ripen perfectly near the shore, in all ordinary years. The Isabella sometimes receives damage in the fruit buds during Winter, so that it bears no fruit. Laying down prevents this. It is probable that this injury is done by the sun, so that it is only necessary to protect the canes by a slight covering of straw or evergreen branches. It is but a small job while pruning, and if done, and the vines receive good treatment otherwise, I am confident that the grape crop can be made more sure than apples. CONNECTICUT.

The Hermitage Wine.

This wine, famous the world over, is so called from the ruins of an ancient Catholic hermitage found on the range of hills where the vineyard is established. The top of the hill is too cold, and at the base the ground is too rich to produce wine of first quality. Along the middle region is a belt of calcareous soil, crossing a granite debris in the subsoil; and this seems to furnish just the best material for superior wine grapes. Lands adjoining, along the Rhone, and other neighboring hills even, in which the soil is different, yield good wine, but it does not fetch more than half the price in market. The *best* of the red Hermitage wines is made from one sort of grape called *Civas;* the white from two kinds, viz.: the *Roussette* and the *Maison*. The vine-growers manure with sheep and horse manure.

The Japan Grape Vine.

In answer to an inquiry, we reply that little seems to be known about it. We are not sure that it has yet been sent to this country, though we wish it might be. From one of our contemporaries we gather the following: Mr. Fortune, the celebrated plant-collector, wrote, last year, from Jeddo in Japan, to the Gardener's Chronicle, that he had seen and tasted a native grape there of superior quality, which he thought would be an excellent fruit for America.

He had lately met in Asia Minor, with Bryant, the American poet, who told him that European grapes generally mildewed in the open air of America. He thought, however, that as other Chinese and Japanese plants have succeeded so well in America, a grape-vine might do the same: at least, it was well worth the trial. Accordingly, Mr. F. having found a first-rate grape in Japan, a native of the coldest districts and very hardy, he informed Dr. Hall, a resident American, and a true horticulturist, of its existence and character, and advised him to send it to this country. Dr. Hall had previously sent home other plants safely, and thought he could venture with this. What this gentleman has done in the premises, we do not know, but shall try to ascertain. Mr. Fortune describes the grape as a fruit of great excellence. Bunches medium size, berries brownish red, thin skinned, and the flavor all that could be desired.

Good Horticultural Prizes.

Among the prizes recently offered by the Caledonian Horticultural Society, we note the following: For the introduction of any new evergreen or deciduous shrub, of an ornamental character, and sufficiently hardy to withstand the Winter of Scotland. For the introduction of any ornamental or useful forest tree, adapted to the climate of that country. For the best model of a rustic chair, with description of materials recommended for its construction, expense, etc. For the best essay, founded on at least five years' observation, on bringing tender flowers and shrubs to such a state of hardiness, as to enable them, in ordinary situations, to endure the climate of Scotland. For the best essay, founded on observation and experiment, on the effects produced on the cion and its products by the stock on which it is grafted. For the best description of those diseases that appear in the bark of trees, which have hitherto been indiscriminately styled "canker," with mode of cure.

In another society, we observe that many of the premiums offered to laboring men consist of farm and garden implements, or articles of household furniture, or of books, trees and seeds. He who carries off the greatest number of prizes is to have the present of a splendid wheelbarrow! Might not our societies gain something in usefulness by adopting some such a system of prizes?

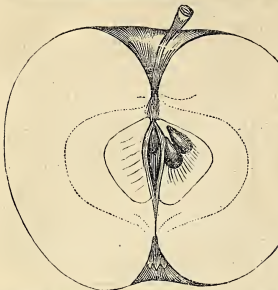
Enthusiasm for Fruit-Growing.

A subscriber, in a note to the Editors of the *American Agriculturist* about his fruit orchard, breaks out into the following strong language: "The most pleasant, most ennobling, and most wholesome of human employments, is fruit growing. It has no seasons of excessive toil, such as other farm labor involves at seed-time and harvest; it has nothing repulsive and shocking, like many operations in the care of, and slaughtering, animals; it is not confining, and soul or body-dwarfing, as are most mercantile, mechanical and professional pursuits. Each department of its labors is fit for saints—even for women; while the harvest—the gathering of the luscious and beautiful fruits—is suitable pastime for angels on gala days! What can be more paradisian here on earth than a snug fruit homestead accessible to a good market? With small capital and easy labor, it will yield a comfortable subsistence, and yet afford plenty of leisure in Winter for traveling, visiting, writing, study, or whatever is prefered. Parents will do well to consider these facts when counseling their sons as to choice of occupation."

THE BEST SHADE TREES.—For the beginner, we would say, plant at first, native, well-known hardy trees. These will include, generally, the white elm; the rock maple, silver, red and black maples; the white ash, the white oak, chestnut, and perhaps a few others. To these, we would add a few evergreens, such as white pine, balsam fir, black and white spruce, and arbor vitæ. Then we would go on with the Norway maple; English, Scotch and Dutch elms; Scotch larch, European Mountain ash, Norway spruce, Siberian Arbor Vitæ and a few other foreign evergreens.

WATER-CRESS.—This is a fine relish in Spring and is proverbially healthy. In Paris, it is cried through the streets under the name of *la sante du corps*,—the health of the body. In its natural growth, it is found along water-courses, but is also raised in artificial ponds. These ponds are bottomed with several inches of rich soil, in which plants are then set out, when the water is allowed to flow over them. They start soon, and grow rapidly.

A NOSEGAY OF FRUIT.—At a late party, we observed this novelty. It was composed of a large variety of different colored grapes, pears, plums, etc., arranged *a la bouquet*, with leaves worked in between them. The effect was fine.



The Westfield Seek-no-further Apple.

Names do not always indicate real qualities, especially among fruits. Many can testify to this from costly experience in the purchase of trees and plants by catalogue; it has frequently been found that the name was almost the only thing the purchased article had to recommend it. In this instance, however, the name, though pretentious, is not misapplied. For all qualities of tree and fruit this variety is unexcelled. It originated in Connecticut, but has been extensively disseminated both west and south, flourishing well in most localities. The Westfield Seek-no-further is thus fully described by Elliott: *Fruit*, medium; *form*, regular, roundish conical, broad at base; *color*, light yellow ground, the sunny side striped and splashed with red, small russet dots shaded around with light russet yellow, often considerable russet about both stem and calyx; *stem* long and slender; *cavity*, open, regular; *calyx*, usually small, closed, sometimes open, with short segments; *basin*, regular form, moderate depth; *flesh*, yellowish, tender, subacid, pearmain flavor; *core*, medium; *seeds*, ovate. Ripens from November to February. When grown in rich, loamy, alluvial soils at the south, it is much russeted, and about the stem the russet has the appearance of rich bronze; progressing northward, it gradually loses its russet, until, on light sandy soils, in Michigan, it becomes a pale yellow ground, with stripes and splashes of clear red, and minute dots. This description will render the fruit easily recognizable. It should have a place in most orchards, both for family use and for marketing.

Experiment in Transplanting—A Hint.

Having occasion, last Summer, to set out a Brugmansia while in full leaf, into the open ground, we observed that it wilted badly, and shed a portion of its leaves. Plentiful watering of top and root, with shading, restored it to partial vigor. But as it did not look quite right for some time, we took a sharp spade and cut all around it, taking off all the long roots close up to the ball of earth. Then, we worked in a lot of rotten dung all about the ends of the cut roots, and applied a heavy dose of water. This treatment was of course followed up by shading and mulching. In the course of ten days, the plant began to grow vigorously, both in root and branch, and soon looked as bright and healthy as one could desire. This result was owing to the fact that when some of the long, coarse roots were cut off, a large mass of new fibrous roots were formed, and that these numerous hungry mouths were supplied with a plenty of food close at home.

Now for the hint. Do we not find here the reason why many transplanted things, such as lettuce, cabbage, tomatoes, celery, etc., as well as some flowering plants, do better when transplanted? The "pricking out" causes them to form a multitude of short, new roots, and being set in rich soil, they grow vigorously. Why not apply this principle in the culture of the melon, cucumber, the grape and the pear? Keep the roots small, numerous, and feed them high? Certainly, it would be a saving of room. This subject is worthy of more careful experiment. It is often advised to be careful not to disturb the roots of trees. The Gardener of the Bible proposed to "dig about and dung" the unfruitful fig-tree. May we not often imitate him to advantage?

A New Mode of Striking Cuttings.

The plan indicated by the accompanying engraving is so sure and so simple as to recommend itself for practice by every body. Any lady can thus rapidly propagate pinks, roses, geraniums, etc., without much trouble or loss. Take a large, wide-mouthed pot, and partly

fill it with small stones or pieces of broken pots, for drainage, as seen at *b*. Then take a pot two inches smaller, stop the drainage hole of this with stiff clay or with a cork, to make it water-tight, as shown at *a*. Set this inside of the large pot, on top of the drainage, so that the brims of the two will be on a level. Now, fill the space between the pots with sandy loam, and insert cuttings all around the pot, as shown at *c*. Have the lower end of each cutting touch the surface of the inner pot. This pot is to be filled with water. Now, plunge the pots in a gentle hot-bed, or, if it is Summer, cover the cuttings with a bell-glass. The moisture will find its way through the sides of the inner pot as fast as the rootlets of the cuttings want it. After a suitable time, the inner crock can be carefully lifted out, to examine the cuttings and see if they are rooted. If they are not, it can be restored to its place without injury to the cuttings. When the young plants are started, they can be taken off, one at a time, with a broad-bladed knife.

THE PELARGONIUM.—It is not altogether an affectation which makes gardeners distinguish between this and the Geranium. The name originated thus: Pelargonium is the Greek name of the bird called stork. It was first applied by the German botanist, Burman, on account of the resemblance between the bill of that bird and the long, pointed seed capsule. The plant, originally from the Cape of Good Hope, has been found, also, in Australia, in Polynesia, and St. Helena.

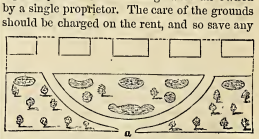
Planning Flower Gardens.

One of the worst ways of planting a flower-garden is to set out indiscriminately, plants of all colors, of different hights and habits of growth, without regard to any system or design. It is enough to make an orderly man's head ache. Here is a verbena, next a poppy; beyond is a petunia, and hard by is a lilac-bush; next is portulacca, and next a morning-glory, and so on. Such a confused mass of things is at best childish. Let there be some kind of system—almost any is better than none. This is a good one: Let the plants on a particular bed be similar in form, or color, size or style of growth. If different colors appear in the same bed, let them be of such kinds as will harmonize well together.

It is a growing custom, and a good one, to have the beds small, and only one color to a bed. Then, when the garden is viewed from the windows or veranda of the dwelling, it has the appearance of embroidery or carpeting. Mr. Loudon recommends drawing out in Winter, on paper, the plan of the garden, and coloring the beds with paint, so as to see what the effect will be. Make the arrangement of colors a long and careful study. When the plan is fixed upon, it will be the simple work of the gardener to find the plants which will give the required colors during the entire Summer, and at the least expense. We suggest this hint to the florists of the *Agriculturist* family, for winter study.

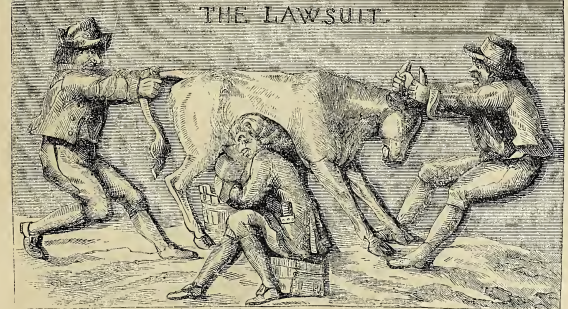
The Embellishment of City Door-Yards.

One excellent mode of adorning city yards is, to throw the front grounds of several buildings into one enclosure, and have them embellished with trees and flowers, under the care of a single gardener. The engraving below will give some idea of this plan. An arrangement of this sort would afford quite a considerable park or pleasure-ground for the different families to enjoy in common. It would furnish a much greater variety of trees and plants than could be possible in any one yard. By committing the premises to the care of a single gardener, it would save much care and expense to each family. The plan would be excellent, especially where the buildings were all owned by a single proprietor. The care of the grounds should be charged on the rent, and so save any



further trouble. The cut represents only one of a great number of plans which might be adopted in laying out the ground. Instead of one wide circular walk, *a*, terminating at the street, there might be several narrow and straight paths running from each door directly to the curb-stone; or there might be any number of serpentine walks, and flower beds and shrubs. The success of the whole arrangement would, of course, depend upon the good understanding maintained among the several tenants. Common interest in an attractive garden would seem to be an excellent means of promoting mutual good forbearance and good will.

[This plan, prepared by an associate, has some advantages, and in some circumstances may be adopted; but as a rule, we should say, let every family have its own garden, and enjoy



This engraving, made for the *Agriculturist* several years since, has been extensively copied, and has, we trust, done at least some good. Indeed, we have heard of several lawsuits in progress, which the "clients" stopped by mutual concessions, after seeing the above picture. The gist of it is plain; the clients waste their strength and substance, while their counsellors quietly enjoy the fees (milk). As we have already remarked, the picture is defective, in not indicating the other attorney drawing his share of the "fees." We are glad to announce that the famous lawsuit here pictured, which began many years ago, as will be seen by the ancient costume of the parties, has at last come to an end. We have in the hands of the engraver for the January *Agriculturist*, a capital original illustration of the final results, which will afford no little amusement and instruction to all.

the pleasure of cultivating it. The healthful exercise, and the improvement of the taste would be lost, if the work be done in common with others, or be delegated to a hired gardener. O.J.]

House Tools—Hints to the "Men-folks."

We dislike to offend by too plain talk, so the reader will please understand that in what follows, we do not refer to him, but to "another man."

On a recent evening we happened into his house (the other man's house) and saw his wife trying to cut out a garment; or possibly it was a patch for a coat for her boy or her husband; but it was hard work, and a ragged edge was left. She made sundry efforts and by clipping several times it seemed to come into about the desired shape. The fact was, the rivet was loose, and as for a cutting edge, that was worn off years ago. We noticed that she looked at her thumb and fingers to see if they were blistered. Three minutes with a hammer to head the rivet, and a grindstone, whetstone, or even a file, to give a cutting edge, would have made all right, saved the wife several hours of time in the course of each week or month, and enabled her to do her work much more easily, and to patch more neatly. But her husband was a "hard working man," and hadn't the three minutes' time. Having some business with him, we found him at the store sitting in his *accustomed* place on the counter.

The wife went to fix up the wood fire, and attempted to lift up a brand with the tongs, but the legs would turn and slip by each other. After several vain trials she pushed up the fire, and swept up the coals that had scattered from the falling brand. One minute's time, with a hammer, would have tightened the joint and made the legs meet square.

A daughter was trying to cut hash or mince meat, but the thug, thug, indicated that the dull knife was only mashing and not cutting the meat. The tired girl showed plainly that she had been at it for an hour or more. Three minutes with the grindstone, or whetstone, or a file, once a month, would give that knife a sharp edge, and save many a pound of elbow grease, many wearisome hours, give that daughter a little extra time to read the *American Agriculturist* (only the other man "don't take it"), and the finely cut tough meat would be far more digestible than when swallowed hurriedly in large pieces. (A Hale's meat cutter, costing $3.50, would cut the hash for a large family in four minutes, or in less time, and do the work excellently.)

One Monday we took dinner at the house of this "other man." The bread was not in smooth cut slices, but appeared as if haggled off from the loaf with the back of a scythe. The dried beef, instead of being in nice thin shavings, nice to look at, and nice to eat, was in thick, scraggy pieces, as if chopped off with a very dull hatchet. The table knives appeared to have been sharpened on the iron shovel handle, or on the stove edge so long, and were so much rounded off, that except from the shape it would have been difficult to tell on which side the edge *had* been. Five or ten minutes with the grindstone would have given a good edge on one side of every knive in the house. How much work it would have saved in the kitchen, in preparing meals, cutting up meats, paring potatoes, etc., the reader may figure up. (If the writer was the wife of this "other man" he would take a few lessons on knife-sharpening and be independent.)

Glancing through the open kitchen door, we saw Bridget *trying* to stop an old leak in a boiler, with a plaster of dough, but it would come off, and the water would run on to the stove and over the hearth. A drop of solder would have saved all this trouble and vexation. If the "other man" had read the *Agriculturist* for November, 1859, page 343, he would have known how to apply the solder himself in less than three minutes.—We have made several calls at this "other man's" house, but the above will do for a beginning. Please show him this copy of the *Agriculturist* and perhaps his curiosity may be excited to read more of his personal matters which will be found in the next volume.

About Artificial Limbs.

It was reported a few years ago, that a monomaniac in France, who believed in the doctrine of chance, conceived the idea that the first human body was the result of a chance aggregation of particles of matter. Instead of trying to prove his theory by reasoning, or on scientific principles, he went to work to demonstrate it by actual experiment. Learning from chemical analyses the kind of atoms entering into the composition of a perfect body, and the proportion of each, he collected the requisite materials, put them into a cylinder, or kind of churn, and commenced operations. His idea was, that, by the long continued agitation of the particles, he would in time bring them into just the proper position and arrangement, and a human body would be the result. He further believed that as he had collected only pure materials, a body more perfect than any one now existing among deteriorated mortals would be the result. If we remember rightly, he was a bachelor, and vowed celibacy until he had produced a perfect woman from his tub or churn. The last heard of him, he was turning away at the crank, as he had been for several years before.

Leaving our monomaniac to work on until his own fragile and ill-composed elements themselves fall asunder, it is pleasing to turn aside and contemplate the real progress that has been made toward con-structing artificial bodies, or in supplying such of the non-vital portions as chance to be lost by disease or accident. With our own eyes we have seen artificial *hands, feet, legs, arms, ears, eyes, noses*, not to mention the more common ones of teeth, and hair, etc.—all of which were so natural in form and appearance, as to escape the notice of the casual observer. Some of these artificial members are so perfect in form and construction as to serve nearly all the purposes of the natural ones. Having a friend who had lost a leg (shot off above the knee in a battle last Spring,) we had occasion to examine the construction of this particular member, and we confess to an agreeable surprise at the perfection to which the manufacture has been carried. After examining some of the most noted forms, any one of which would be a great acquisition to a legless man, we were led to give the preference to those made by Mr. Selpho, of this city. We have not room for a minute description of the construction, and of the means and appliances by which the manufacturers imitate the action of the natural limb. Essentially, the external appearance of the limb, in form and color is an exact imitation of the natural one. The structure is an ingenious combination of tough wood, leather, steel, India rubber, etc., by which lightness, strength, pliability and durability, are admirably secured. Fig. 1, gives the general appearance of an unclothed leg of nearly full length. Inside of this, as partly shown in fig. 2, are joints,

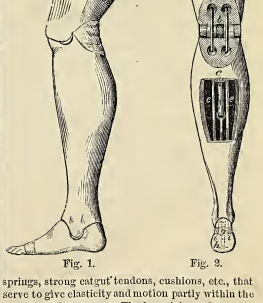


Fig. 1. Fig. 2.

springs, strong catgut tendons, cushions, etc., that serve to give elasticity and motion partly within the control of the wearer. The knee joint and the heel joint, bend and yield to pressure almost like the natural structure. We had the engravings specially made for the *Agriculturist*, but find it difficult to explain the various parts without having the reader present to see the actual limb, and will therefore not attempt it. The leg, as made by Mr. Selpho (of

No. 516 Broadway, New-York,) seems to excel in the simplicity of the internal machinery, and the consequent little liability to get out of repair; in the strength and broad bearing of the knee joints; and especially iu the arrangement by which a side motion is given to the foot, so that in steppiug on an uneveu surface, or upon an inclined plane, the foot yields laterally, and the bottom and ankle joint adjust themselves to the inequality.——*Artificial Arms* are made in almost equal perfection. As an illustratiou, we slipped one of our arms into an artificial one so as to be able to use our shoulder joint only, and yet by means of the concealed strap, tendons, and springs. we eould take off our own hat with the artificial fingers, place it on the table, and return it to the head agaiu.——We are glad to know that arrangements are made to supply our maimed soldiers with these most valuable artifieial limbs, at a low price. The Government allows $50 to soldiers for each limb lost, towards proeuring an artificial one. A moderate additional contribution from frieuds will pay the extra eost. Particulars as to price, etc., can be obtained by addressing the manufacturers as above, or in an advertisement.

A Cutting Board Convenient.

Ladies, especially those who do the cutting at meetings of Sewing Societies, Relief Associations, etc., know how tiresome it is to stand at a table all the afternoon or evening, preparing work. At one of these meetings the other evening, we noticed a simple and convenient cutting board, which may be in general use, but we had not before seen one. It is a board about 3 feet long, and 1½ to 2 feet wide, to hold upon the lap. On one side a half circle is cut out so that it fits partly round the body, and the arms may rest upon it. The other side is partly rounded to take off the sharp corners that would otherwise stand out in the way. Such a board is convenient both for cutting and mending. Auy husband or son will make oue in a few miuutes. The board should be thin, and of light seasoned wood. We will suggest an addition, thus: Bore a hole in each outer corner, and put two sticks, say broom sticks, for supporting legs to the outside; the other side rests on the lap. The sticks can be then taken out when not iu use. We may claim a patent for this "improvemeut," but it is free to all readers of the *American Agriculturist*, which includes about everybody and the rest of womankind.

Housekeepers, Help Each Other.

A REQUEST.

We respectfully solicit the aid and co-operation of all interested in housekeeping to help improve this department of the *Agriculturist.* During the past year several hundreds of items, hints and suggestions have been given, of which some at least have beeu interesting and useful we trust. But the household department has not been as full and varied as we could wish, or as we intend to make it. Our absence a part of the time has somewhat prevented as much personal attention to these columns as we expect to give hereafter. But while we shall do all we can, we ask our readers for abundant contributions. Wheu two or more housekeepers spend an hour together, each one usually gains some new hint or idea to put in practice. No one makes a day's visit at the house of a friend without seeing or hearing of some mode of doing a thing that leads to improvement in her own operations. Now we would like to gather up these ideas and spread them before tens of thousands. What is uew to any oue person, will be likely to be so to a great many others. We believe that there is just as great a chauce for improvements to be made in the house, as on the farm—iu labor saving implements, in the most important topics of the care and health of the children, in the preparation of good, healthful, economical food, etc. Usually, when we solicit information, the reply is, "I am not used to writiug for the papers"—especially from those who are most excellent practical housekeepers. But this need not be an excuse. We do not ask any one to edit; give us particulars, the ideas, the hiuts, no matter in how common language, and we will attend to putting them in shape for the public. Let all help in this matter, not merely those who can better tell how to do a thing than do it, but those of the opposite class. She is a public benefactress who gives to a thousand others a single hint that tends to lessen labor and care, or leads to even the slightest improvement in any common household operation.

To Cure Hams—Loss of Weight.

Johu C. Bishop, Fond du Lac, Wis., writes to the *American Agriculturist:* "I have never failed of having most excellent hams by using the following recipe—the shoulders are equally good, only fatter: Rub the hams thoroughly around the bone with salt, usiug the best quality. To 4 pails water add one quart molasses, six quarts salt, and one tablespoonful of saltpetre: they should remaiu in this pickle covered, five weeks. Cobs are preferable to any other article to smoke with; sack and whitewash, and you will have first quality hams the year round. In packing my pork last Fall, it occurred to me to ascertain how much is lost in weight by smokiug hams. I cut out a ham which weighed 24¼ lbs. After taking from the pickle, in which it had remained some 5 weeks, it weighed 25¼ lbs. To-day, one month after smoking, it weighs 22⅛ lbs., having lost over 3 pounds. A barrel of side pork weighing 200 lbs. that I packed freed from boue and most of the lean meat, on being re-weighed had gained 8 pounds.

Mince Pies—Spirits in Cookery.

Mrs. M. L. Thomson, of Falmouth, Ky., sends for the household department of the *American Agriculturist*, the following: Take 4 lbs. of boiled meat (a boiled beef's heart is very good), ½ pound suet, 4 ounces cinnamon, 2 ounces mace or nutmeg, 1 ounce cloves, 4 pounds raisins, 1 pint molasses, 1 quart brandy, and sugar euough to make quite sweet. To all the above add an equal weight (nearly 12 lbs.) of tart apples chopped fine. It will keep five or six months. As used for pies from time to time, add just before baking a tablespoonful of vinegar, or old cider, to each pie. [The above is doubtless good, but a serious objection is the amount of brandy. The taste for alcohol which leads to its more frequent after use, and often to excess, is very often created by the use of wine or brandy sauces, brandied fruits and pies, etc., eaten at the paternal board. Were there not this danger, we should less object to *pure* brandies and wines occasionally in cooking. As it is, we thiuk it always safer to eschew all alcoholic mixtures in cooking. One generous, noble young man lost to society through such means, is a greater loss to his friends, aud to society, than the sacrifice of all sweetmeats, condiments, aud stimulants, for ten thousand tables. It is the generous hearted, active, energetic, social young men, those worth most to society, who are by far the most liable to be overcome by evil habits, for these take the strongest hold upou such.—ED.]

How to Cook a Rabbit.

L. E. Palmer, Luzerue Co., Pa., writes to the *American Agriculturist:* At the preseut season, country families, especially those which number a trap-setting juveuile or two, are coming into possession of various "small deer" of this sort. Many questiou whether it is "worth while" to dress aud cook these chance acquisitions. Plain housekeepers are apt to be shy of wild game from the idea that it requires some intricate process to render it really excellent. Rabbits cooked in the following simple way are prouounced better than that great standard of comparison—'chicken'. Prepare for stewing the same as with fowls, aud after par-boiling, change the water, adding salt. Three hours steady stewing is not too much for an old rabbit; the great point is to get it teuder, but not ragged. When cooked, add two-thirds of a teacup of butter, and stir in while boiling, two tablespoonfuls of flour in a cup of water, theu a little pepper. Toast to surface browu, but do not harden, three slices of bread; butter them freely while hot, lay on the platter, and pour the stew over them.

Another Pennsylvania lady, Mrs. E. McC., Northampton Couuty, whose husband is equally expert with a gun in bringing down rabbits at home, or as a "militia man" ou the southern border of the State, gives us her method of preparing a rabbit as follows: After skinning they are thoroughly freed from blood with cold water. They are then left over night in weak salt water, which is poured off in the morniug, and new salt water added, in which they stand until ready for cooking. This water is made just salt enough to fit the flesh for eating. They are then boiled until tender, when the meat is taken out, aud flour and butter, first rubbed together, is stirred in, and well peppered, and the whole poured over toast, upon which the meat is laid. A few sprigs of parsley added, improve the taste for many persons.

A Stuffed Beefsteak.—Prepare a dressing of bread scalded soft aud mixed with plenty of butter and a little pepper aud salt. Lay it upon one side of a round of steak, cover with the other and baste it down with needle and thread. Salt and pepper the outside of the steak and place in a dripping pan with half an inch of water. When baked brown on one side, turn and bake the other.

The Queen of Puddings.—L. E. Palmer, Luzerne Co., Pa., contributes the followiug to the *American Agriculturist*, and challenges any housekeeper in the country to give any mode of preparing a more delicious light pudding: One piut of nice fine bread crumbs to one quart of milk, one cup of sugar, the yolks of four eggs beaten, the grated rind of a lemon, a piece of butter the size of an egg. Bake until done but not watery. Whip the whites of the eggs stiff and beat in a teapcupful of sugar in which has been stirred the juice of the lemon. Spread over the pudding a layer of jelly or any sweetmeats you prefer. Pour the whites of the eggs over this and replace in the oven aud bake lightly. To be eateu cold with cream. Is second only to ice cream, and for some seasons better.

Another Nice Pudding, by the same contributor: Three tablespoonfuls melted butter mixed with one cup of sugar; 1 egg well beaten; 1 pint of flour; 2 teaspoonfuls cream tartar; 1 of soda; 1 cup sweet milk. Beat well, and bake 30 minutes. Serve hot with the following sauce: Two cups sugar with 1 cup of butter; 1 cup of currant or other wine added a little at a time, as the butter and sugar are melted—the pan containing it being set in hot water ten minutes or so. ["Spirits" agaiu.]

Pumpkin Bread.—Coutributed to the *American Agriculturist*, by Mrs. S. Washburn, Westchester Co., N. Y. Stew oue small pumpkin, in the same manuer as for pies; while boiling, stir in Indian meal until it becomes of the cousisteuce of mush, adding a teacup of molasses and a little salt. Theu take it out in some wheat flour—have your sponge light—and when sufficieutly cool, mix, mould and bake.

Potato Pie.—Contributed to the *American Agriculturist* by Indamora Hyatt, Westchester Co., N. Y. Mix the crust iu the same manner as for chicken or beefsteak pie, aud place it in a deep pie dish or dripping pan; cut into it one small onion, and fill eveu full with fiuely sliced potatoes; add a little butter, and pour into the pan as much sweet milk and cream as it will contain. Season with salt and pepper to suit the taste; cover aud bake in a slow oveu. [Pray, leave out the ouion.—ED.]

WORKING BACKWARD.—A worthy Scotch couple, when asked how their son had broken down so early in life, gave the following explanation: "When we began life, we worked hard, and lived upon porridge, and such like, gradually adding to our comforts as our means improved, until we were able to dine off a bit of roast meat, and sometimes a boiled chuckie (chicken); but Jack, our son, worked backward; he *began with the chuckie first.*"

Sunday School Lessons for Two Years.

The following 104 lessons, averaging 7 to 8 verses, are arranged in chronological order, with names of the leading copies of the New Testament History are printed in capitals, and designed for the first year. They are taken from the chapters that give within the limits of one lesson the most complete narrative of the several events. The pupil learning them will have the groundwork of the Gospel History and Chronology started in his mind. The second series of 52 lessons, for another year, printed in *italics*, are placed in their proper places in order of time. If every Teacher and Scholar has a printed copy, there will be no room for the usual excuse, "I didn't know where the lesson was." See Almanac on the back of this, for any year.

	Subject.	Chapter.	Verses.
1—ANGELS AT BETHLEHEM	Luke ii.	8 to 14	
1—*Testimony of Simeon*	Luke ii.	25 to 32	
2—VISIT OF THE WISE MEN	Matt. ii.	1 to 9	
2—*Slaughter of the Innocents*	Matt. ii.	16 to 23	
3—CHRIST AT THE AGE OF TWELVE YEARS	Luke ii.	41 to 52	
3—*The Light of the World*	John i.	6 to 12	
4—THE BAPTIST'S MISSION	Matt. iii.	1 to 12	
4—*The Baptist's Preaching*	Luke iii.	7 to 14	
5—CHRIST'S TEMPTATION	Matt. iv.	1 to 11	
5—*Christ's First Miracle*	John ii.	1 to 8	
6—INTERVIEW WITH NICODEMUS	John iii.	1 to 12	
6—*The Samaritan Woman*	John iv.	19 to 30	
7—CHRIST EQUAL WITH THE FATHER	John v.	18 to 30	
7—*Evidence of Miracles*	John v.	33 to 40	
8—DOCTRINE OF THE SABBATH	Matt. xii.	25 to 30	
9—*The Beatitudes*	Matt. v.	3 to 10	
9—PARABLE OF THE SOWER	Matt. xiii.	3 to 9	
10—*Christ Teaching by Lake*	Luke v.	3 to 11	
10—COMMISSION OF THE TWELVE	Matt. x.	1 to 7	
11—JOHN'S IMPRISONMENT AND DEATH	Matt. xiv.	1 to 12	
12—CHRIST THE BREAD OF LIFE	John vi.	26 to 33	
13—*The Syrophœnician Woman*	Matt. xv.	21 to 28	
13—THE TRANSFIGURATION	Luke ix.	28 to 36	
14—NECESSITY OF CHILD-LIKE TEMPER	Matt. xviii.	1 to 7	
14—*Parable of the Unmerciful Servants*	Matt. xviii.	21 to 35	
15—APPOINTMENT OF THE SEVENTY	Luke x.	1 to 7	
15—*Freedom of Believers*	John viii.	31 to 38	
16—PARABLE OF THE GOOD SAMARITAN	Luke x.	25 to 37	
16—THE LORD'S PRAYER	Luke xi.	1 to 8	
18—CHRIST FULLY OFFERED	John x.	1 to 9	
18—*Christ the Resurrection*	John xi.	20 to 27	
19—PARABLE OF THE PRODIGAL SON	Luke xv.	11 to 19	
19—*The Rich Man in Hell*	Luke xvi.	19 to 31	
15—*The Wicked Husbandmen*	Luke xx.	9 to 16	
15—*The Great Commandment*	Matt. xxii.	34 to 40	
20—THE LORD'S SUPPER	1 Cor. xi.	23 to 29	
20—*The Vine and its Branches*	John xv.	1 to 8	
18—*The Comforter Promised*	John xvi.	5 to 12	
21—THE ASCENSION	Luke xxiv.	45 to 53	
22—SEIZURE OF CHRIST	Luke xxii.	47 to 53	
23—PETER'S DENIAL	Luke xxii.	54 to 62

52—*The Millennium*	Rev. xx.	1 to 8	

Entered according to act of Congress in the year 1863, by ORANGE JUDD, in the Clerk's Office of the District Court of the United States for the Southern District of New York.——The above table of Lessons originated with Orange Judd, Sunday School Superintendent at Flushing, Long Island. The final selection and arrangement of the Lessons were made by DR. JAMES STRONG, S. T. D., (author of the Harmony of the Gospels, etc.) The lessons were copy-righted simply to stop their improper use for speculative purposes. Any school can adopt them. Copies can be obtained by addressing Mr. O. Judd, Editor of the *American Agriculturist*, New-York City.—Cost, 50 cents to $2.00 per *hundred*, according to quality of paper, postage, etc. $1 will pay for 100 on fair paper, including *postage* by mail.

To S. S. Superintendents and Teachers.

Of the annexed series of lessons, those in capital letters were published last year and have been widely used. We shall have both of these series printed, as here, neatly, with a Calendar of Sundays upon the back to show the lesson in either series for any Sabbath from 1863 to 1869 inclusive. When desired, three sample copies will be mailed post-paid for a three-cent stamp.

But we now wish to call special attention to a very excellent little *Question Book* on these lessons which has several new and valuable features, and which we feel quite sure will please all, and come into general use as soon as known. It is now in press and will be out in a week or two. It gives each lesson in full, with the time and place of occurrence; a condensed history connecting each lesson with the preceding one; a series of questions directly on the text for small scholars; a series in small type for older scholars and adults, with each question answered directly or by a reference. These questions and answers give much information not accessible to the general reader. The book is thus a history, a chronology, and a commentary, as well as a question book. The price will be only 10 cents for 112 pages, in paper covers, and will be specially useful to teachers not supplied with Commentaries and other books for reference. We are free to speak thus strongly, as we have not the slightest pecuniary interest in the book. Send and get a specimen copy which costs only 12 cents post-paid.

The Editor with his Young Readers.

Long Days—No "Adieus."

Well, young friends, we have journeyed along together through another year. It seems to us but as yesterday that we wrote the closing item of 1861. To some of you the year has probably appeared to be very long. Every successful year of your lives will seem shorter than the preceding one, and for this reason: When the mind is fully occupied, we take no note of the passing moments; we are so intent upon business or pleasure, that the minutes and hours fly even too swiftly. Now, the older one grows, the more thoughts he has to occupy his attention, little boys and girls do not have to trouble themselves about their parents or friends provide their food and clothing, and they are themselves often troubled to find play enough to fill up their hours and days. When the real work of life comes, and you want to accomplish a great deal in a short time, you will be heartily wishing for longer long days.—But we started to say something about the closing year, and to write a parting paragraph. Yet, on a second thought, this does not seem necessary, for we hope all our *Agriculturist* family will come around the common table another year. We can not spare one of them. The Editor in Chief looks forward to many pleasant days in the coming months. This year he has been absent, seeking knowledge in foreign lands, and has had little to say to you except by letters. Some of the letters written in Europe are not yet published. These, with the engravings, will interest you, he hope. There were very curious things seen in France, Switzerland, Germany and Belgium, not yet described. And there are many other interesting things to fill up the pages devoted to the young people. The good associate editors have done what they could for you during the past months, but the Editor himself thinks that no one else can have quite so good a time with the little folks, as he can. He intends to be "at home" most of next year, and he cordially invites all his former young friends to gather around him, and bring new ones as many as they can persuade to join our goodly company. We shall begin at once to prepare the January number, so as to have it all done before Christmas. Please hurry along the names, old and new, so that our mail clerks can get them all entered on the books, ready to start off the next number in good time. Expecting to meet you all again next month, we will not write any "adieus" or "farewells" here, but cordially wish you all a MERRY CHRISTMAS.

Served them Right.

A correspondent relates that the story of "Peter after a Rabbit," in the November *Agriculturist*, reminds him of the following occurrence: A gentleman, after riding some distance in one of our City cars, stepped out and left a small package lying on the seat. The cars went on, and when at a distance of several blocks, a rough looking customer also got out, taking with him the package, which he had observed as soon as the gentleman left it. Almost immediately he was followed by another man of about his own stamp, and presently loud quarreling was heard between the two in the street. Each insisted that the package belonged to himself. The words "liar" and "thief" were quickly followed by a rough and tumble fight, each striving to get possession of the prize. In the struggle both fell; the package, which proved to be a bottle, was broken, and its contents were liberally spilled over both combatants, when they both set up a howl of pain. The bottle was filled with strong sulphuric acid, which quickly burned into their flesh like fire. This effectually stopped their fighting, and gave them a pretty severe illustration that "honesty is the best policy."

Puzzled for an Excuse.

Some years since while the cholera was prevalent in Virginia, the inhabitants, particularly the negroes, were greatly alarmed. A most gifted one was a negro boy, who, having heard his father say the cholera would soon be along that way, left his work one day and betook himself to the woods. Here he was found by his overseer, soon after, fast asleep. Being taken to task for leaving his work, he excused himself on the ground that "not being prepared to die, he had gone to the woods to meditate." "But," said the overseer, "how was it that you went to sleep?" "Well, I don't know, massa, how dat was 'xactly," responded the negro, "but I speck I must have overprayed myself!"

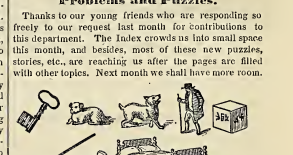
"Random Descriptions"—An Amusing Game.

A lady subscriber sends to the *American Agriculturist* the following instructions for playing an amusing game, which may be properly called "Random Descriptions." One of the party being provided with slate and pencil, calls on each of the others in turn to name some descriptive adjective, as good, pretty, ugly, fast, slow, etc. These are written in a column at the left of the slate. The writer then places his pencil opposite one of the words and calls for the *name* of one of the party, which being called for, is written next to the *adjective*, and then the name of the whole company is written in turn in each opposite the adjective which comes in the order of the list.

The writer now commences at some other part of the list, and each of the company names some *locality*, as "on the house," "under the barn," "in the woods," etc.; and these are added, one to each name. In the same manner, some *act* is next written down, opposite the preceding, as "hauling saw-logs," "sleeping soundly," "shelling corn," etc. When all is completed the sentences are read aloud. The ludicrous situations described will often cause the greatest merriment. Thus it may happen that "Sweet Susan was before the looking glass making faces;" or that "Slow John was on the railroad, running a race with the engine;" or that "Long John was hunting rebels, in the wash-tub." Of course, much of the fun will depend on keeping the sentences secret until all are read.

Problems and Puzzles.

Thanks to our young friends who are responding so freely to our request last month for contributions to this department. The Index crowds us into small space this month, and besides, most of these new puzzles, stories, etc., are reaching us after the pages are filled with other topics. Next month we shall have more room.



No. 20.—*New Rebus*, which contains good advice.

No. 21.—*Riddle.*

A four handed rider, on a two legged steed,
Whipped up the feathers and made very good speed.

Can you solve this riddle. Our answer will be an amusing engraving; look out for it in the next number.

No. 22.—*Arithmetical Problem*, proposed by Willie Perry, Waukesha Co., Wis. When gold is worth 22 per cent. premium, reckoning a paper dollar as par, at what per cent. discount is paper money reckoning gold as par?

No. 23.—*Arithmetical Problem*, by the same: A owns 3-5ths of a calf, and B, 2-5ths. They agree to admit C as a partner, and to divide the calf equally; C to pay $1 for his third. How shall A and B divide the dollar?

Answer to *Rebus* No. 19 (page 345, November).

"The cook doth crow to let you know
What time to rise if you be wise."

Correct answers to No. 19, have been received from C. L. Shubrick, Hattie Hanford, Mary A. Purdy, Jno. D. Talbot, Elsie B. Blackman, J. G. Barnett, "Jennie," A. B. Martin, Fannie J. Minor, C. S. Wheeler, Elgin Angell, A. C. Siewers, M. J. Burr, Fred. Cook, (Rebus pretty good, but too difficult), Kate E. Davison, "Beulah," Mary Esther, Mary Eva Haggerty, Lila J. Chapman, Marshall T. Bryan, Frank R. Conger, Aaron E. Frost, Werdna Nohiff, D. B. Vanyckel; H. Slater, and others coming in.

"SHOO!—GO AWAY!"—*(Engraved for the American Agriculturist.)*

No wonder the little fellow seen in the engraving is in trouble. He has begun to experience what all will find to be true, that even prosperity has its difficulties. The fowls that cared little for him before he became proprietor of that tempting slice of bread and butter, are now more attentive than is pleasant. Should he unfortunately drop it, they stand ready to snatch it away, and the rooster, more bold than the rest, seems meditating on the chances of success in making a direct attack to secure the coveted prize. Just so he will find it in older life. Success always causes envy, and this alienates friends and raises up enemies.

That Unfortunate "H."

Many amusing mistakes and ludicrous sentences have been made by the wrong use of the letter *H*, so common among the natives of some parts of England. They omit it where we use it, and use it where we do not. Here are two or three. The first we find in an exchange. The proprietor of a saloon in our neighborhood applied to an English sign painter to letter his window. Before commencing, the painter was asked, "can you spell *saloon*?" "Certainly," was the reply; "s-hay-bell, two hoes, and a hen." This would make quite a rebus if pictured out.

An English servant girl in the family of one of the editors of the *Agriculturist*, once proposed the following puzzle to one of the children: "What does two hens, two hoes, a bell, and a d spell. The child stood amazed that the girl should "say a naughty word," as she told her mother. The girl being asked for an explanation, said the word was "London," which you see is made up of the letters two *n*'s, two *o*'s, an *L*, and a *d*: the unfortunate *h*, was the cause of the "naughty word."

We recently heard a still more ludicrous instance during a sermon by an English minister. He was noticing the fact that man has two different orders of faculties, the mental and the moral. "Thus," said he, "for illustration, man may be compared to a double louse;" at least it sounded so to his hearers. He intended to say a double house, but unfortunately dropped the h, and ran the two words together, making sad work with his illustration.

A Sharp Newsboy.

Not long since a military officer was waiting at a Depot for the arrival of a train of cars. The newsboys soon discovered that he had no morning paper, and swarmed around him like flies, teasing him to "Buy the Sun—Times—Tribune?" He drove them all away but one, who was determined to sell him at least one paper. As a last resort, the officer cried out "I can't read a word, I tell you—so be off!" "Can't read, eh?" replied the news boy looking quizzically at him, "well now old feller, I'll fix yer: 'ere's a Illustrated News, or a *American Agriculturist*. Just look at the pickers! You needn't read a word; them pickers speak to the commonest understanding." The officer could stand it no longer, and bought half a dozen papers as a reward for the boy's ingenuity.

A Trick of the "Bogie."

In Great Britain the custom prevails of celebrating the evening before "All Saints Day," (Nov. 1st) by various games and amusements. Some superstitious people believe that on that evening—called Halloween, or All-Hallows—spirits, both good and bad, or fairies and bogies, as they are termed, are particularly active in bestowing good gifts, or in playing pranks upon mortals. Among other games played on Halloween is one called "bobbing for apples." A tub filled with water is placed upon the floor, and a few large apples are put in it, which float upon the surface. The company endeavor to get a bite from the apples without touching them with the hands. This causes great sport, as in their eagerness, they frequently get a ducking instead of an apple. The custom is kept up by some families coming here. Last Halloween the children of a neighbor of the writer, were engaged in this play, in which Bridget the servant girl joined them. After several failures she made a desperate grab, but immediately raised her head with a cry of distress, and to the astonishment of the company remained with her mouth wide open, unable to close it or to utter a word. Poor girl: she was sure the "bogie" had played her a trick, and she was in the utmost alarm. The father of the family hearing the cry, examined her face and found that in bobbing at the apple she had opened her mouth so wide as to dislocate her jaw, and a surgeon was necessary to replace it. The girl, however, was not easily convinced that the "bogie" had not played her a trick, and nothing could now tempt her to bob for apples.

The Successful Mechanic.

Many years ago a young man, a house painter by trade, went to Savannah to start in business for himself. He took a shop, hung out his sign, and looked for customers; but none came. There appeared to be painters enough in the place already, and his prospects looked dark. What should he do? Give it up, return to the North, and work as journeyman again? He was not that kind of man. If customers would not come to him, he would go to them. Early one morning, with over-alls on, and paint pot and brushes in hand, all ready for work, he started out, and walked briskly through the principal streets as though in haste to commence a day's work—which indeed he was. Presently a gentleman stopped him with, "I see you are a painter." "Yes sir."

"Do you do business on your own account?" "Yes sir." "What can you do for me?" Most men would have answered "right away," but our friend was more shrewd, and replied, "Probably in a week or so."

"But I want it done immediately."—"I would like to accommodate you, and will try to; I will send a man by day after to-morrow, or I will come myself."

Of course he went himself, and found a long and profitable job on the gentleman's plantation, which he completed so well that others noticed it, and were glad to employ him; and in a short time he was at the head of the largest business of the kind in Savannah. He has since changed his business, and were we permitted to name him, he would be at once recognized as the Principal of one of the most important manufacturing establishments in this country. Remember, boys, that he owed his success to *perseverance, shrewdness* (not cunning, but careful thought), and *faithfulness*.

A Farmer Happier than a President.

No doubt many of our young readers suppose a Governor must be a happy man, and a President, one of the happiest, if not the most so of any man living. Here is the opinion of one who had filled both positions, expressed in his last will and testament, where men are supposed to speak their honest convictions. "I, Martin Van Buren, of the town of Kinderhook, heretofore Governor of this State, and more recently President of the United States, in the last and happiest year of my life, *a farmer in my native town*, do make and declare the following to be my last will and testament, etc." So thought Washington, Jefferson, Harrison, and multitudes of other great men, who could judge from actual experience as farmers.

Will You be an Agent?

The Publisher desires to secure the best special agent for the *Agriculturist* in every town and neighborhood. Judging from the fact that it is very hard for himself to say no to a proper request from a good child, he thinks the most successful agents will be his young readers, and he hereby commissions every boy and every girl who receives this, to act as a *special agent* to tell others what the *Agriculturist* is, and to invite them to take it. We can not this year afford much commission, (printing paper is too high) but we offer some good premiums to those who get large clubs. Those who do not get a club large enough to secure a premium, we will try to repay for their efforts by sending them just as many good things as we can crowd into the pages of the paper. We will try to give you some hints that will be worth more in after life than bags of gold; and not forget to put in many interesting stories, pictures, puzzles, etc. Will you please to accept the agency, and procure one, two, three, or more new readers? We believe you will gladly do so, and tender our thanks in advance. Who will speak out first, who second, who third?—all may speak together. A little practice in the art of persuasion will be useful. It is a good thing to be able to argue well. Try a pleasant argument with that neighbor who has not hitherto been convinced that it would do him and his family good to read such a paper as the *American Agriculturist*.

PREMIUM LIST,

For 1863---Volume XXII.

Good Pay to Voluntary Agents who attend to Collecting and forwarding Clubs of Subscribers to the American Agriculturist.

(Premiums open to all who Desire them.)

Every subscriber is invited to renew his own subscription, and to solicit others to subscribe. But to all those who will take the trouble to collect and forward CLUBS of subscribers, we offer a remuneration in the form of *first-rate* articles, as named below. (The pay thus offered is much larger than we could pay in cash, as we get these articles on extra good terms when *for premiums.*)

☞ WE WISH IT DISTINCTLY UNDERSTOOD *that these premiums are offered in good faith—no cheap, trashy, imperfect, poorly made, or second-hand things, will be sent out, but each article offered, is the best of its kind, and every one will be selected by the publisher from the very best manufactured. They will be the best sold in the market at the prices named.*

☞ *We make no distinction between new and old subscribers* in giving these premiums, but it is expected that every canvasser will not only gather up the names of old subscribers, but also secure a large number of new names.

☞ Every person collecting names for premiums, should send the names of each list of names—one of them marked "For Premiums," and also with the name of the sender.

☞ Every person collecting names for premiums, should send the names with the money as fast as obtained, so that the subscribers may begin to receive their papers; Two copies of each list of names should be sent—one of them marked at the top "For Premiums," and also with the name of the sender. The premium will be paid as soon as any club is made up—if duplicate lists are sent.

☞ Any person who has commenced sending in names at 80c. and finally fails to get the higher number of names, can fall back upon the smaller number, by remitting 20 cents extra on each of the smaller number of names required.

☞ Clubs need not be all confined to one Post Office.

Table of Premiums for 1863.

Names of Premium Articles.	Price of Premiums.	Names at $1 each.	Names at 80 cents each.
1—Good Books—*See terms below*			
2—Best Family Clothes Wringer.....	$7 50	18	37
3—Improved Washing Machine.....	$4 50	10	23
4—Sewing Machine, (Wheeler & Wilson)	$15 00	60	130
5—Sewing Machine, (Wilcox & Gibbs)	$15 00	60	130
6—Aneroid Barometer.....	$7 50	18	44
7—The Aquarius.....	$10 00	30	63

24—Eagle Plow No. 20.....	$9 25	28	62
25—Hay and Straw Cutter (best).....	$8 00	26	58
26—Steel-tooth Cultivator (best).....	$7 50	24	51
26—Family Lard and Wire Press.....	$3 00	21	55

DESCRIPTION OF THE PREMIUMS.

Premium No. 1—Good Books.

Any person sending 16 or more subscribers, may select from our book list, (page 376,) to the amount of 12½ *cents for each name, at the club price of 80 cents, or to the amount of* 33⅓ *cents for each name, at* $1 *each.* Farmers' Clubs have frequently joined together and obtained a good library through these premiums. N. B.—The books will be *delivered* to the recipients, (by mail or express,) *free of all cost.*

No. 2—Family Clothes-Wringer.

This is a first-rate household implement—a great saver of garments, and of hard work. With this machine set on the edge of the wash-tub, the garments are easily and rapidly passed between two India-rubber rollers, the water falling back into the tub, and the garments dropping into a basket, in a drier condition than can be wrung by hand, and therefore more quickly dried on the line. A child can in a few minutes wring out a tubful of clothes. We have had one in constant use in our family for nearly three years, and it is still as good as new. The machine offered, No. 2, is just the thing for family use. It is provided with cogs to move the rollers together, so that it is not possible to tear garments, as is the case with cheaper Wringers not provided with cogs. We present one of these No. 2 Wringers to any person procuring and forwarding 18 subscribers at $1 each, or 37 at the lowest club price, (80 cents each.)

Premium No. 3—Best Washing Machine.

The **Nonpareil Washing Machine** we have had in use in our family for nearly a year past, and it has not only driven out half-a-dozen placed there on trial, but has really gives excellent satisfaction. It is the only machine, out of twenty we have tried, which the "help" cheerfully use without compulsion. It is a labor-saver and a clothes-savcr—two important considerations. (See descriptive cut, and advertisement on page 318.) The clothes are put in, in quantity, and quickly washed by simply turning a crank. The balance-wheel adjusts the force required, so as to make the turning easy. Take it all in all, it is the best Washing Machine we know of, and is worthy of a place in every family. They are of three sizes; we select No. 2, as the best size for common family use. The price of No. 2 is $7.50. This machine will be present to any one forwarding 30 subscribers at the regular price, ($1 each,) or 70 subscribers at the lowest club price, (80 cents.) The machine can be sent to any point as freight, or by express, and will be forwarded, free of all expense, except the freight after leaving the city

Premium No. 4—Sewing Machine.

90 Subscribers at $1 each, (or 130 at 80 cents each,) will entitle the person sending them to **Wheeler & Wilson's best $45 Sewing Machine,** (including **Hemmer**), new from the factory, and of the very best make. There is no better family machine than this made, as we have used it nearly *five years'* use in our own family, in connection with other machines. We want no better. The terms on which it is offered are, with stable many families we are sure one without direct outlay of money. The Premium Machines will be selected new at the manufactory, and will be forwarded, well boxed, with full directions for setting up and using, and with no expense, except for freight.

Premium No. 5—Sewing Machine.

60 Subscribers at $1 each, (or 98 at 80 cents each,) will entitle the person procuring them to **Wilcox & Gibbs' $35 Sewing Machine,** including a set of **Hemmers.** This is the best machine of its kind, (sewing with one thread,) and has several points superior to other machines. It is neat, well made, and in its operation will have the credit of one in our own family for more than two years, we think highly of it, and can recommend it to those who can not afford to buy the higher priced double thread machines. Many of our neighbors think this machine ahead of all others. Premium 5 will be selected and sent the same as No. 4.

Premium No. 6—Barometer.

10 Subscribers at $1 each, (or 14 at 80 cents each,) will entitle the person getting up the club to one **Aneroid's Aneroid Barometer,** (Price $7 50.) This is a good, portable Instrument, and valuable to every person as a weather-glass. See a full and satisfactory notice on page 377, December No. It will save to the farmer and others many times its cost, as a weather-indicator. These instruments resemble a large watch, is inches in diameter, and 2 inches thick. Each one is in a neat leather case, and when sent to a distance, this is packed in cotton, in a wooden box 4½ inches, and can go anywhere, by express or otherwise, with perfect safety.

Premium No. 7—The Aquarius.

This is a capital instrument, valuable to have in every house. It is a portable hand force-pump, which any one can easily set up in a moment's warning, and throw from a pail or other vessel a steady stream of water upon a fire in a house, or elsewhere. It is supplied with both a jet-pipe and a rose, or sprinkling pipe, and can be used for washing windows, carriages, &c.; for sprinkling trees, plants, destroying insects, &c., &c. With it, it is easy to wash the second and third story windows, and to sprinkle and cool the roofs, while standing upon the ground. Such an apparatus will often enable a person to so use a bucket or two of water as to extinguish a fire breaking out where it could not be reached with water dashed on from pails. It is supplied with suction and injection India-rubber pipes, and with air-chambers to keep up a steady stream. The price is $10 00, and it can be sent anywhere as freight, or by express. (Price $16.) We will present an **Aquarius** complete to any one sending us 32 subscribers at $1 each, (or 47 at 80 cents each.)

Premium No. 8—Melodeon.

125 Subscribers at $1 each, (or 237 at 80 cents each,) will entitle the person getting up the club to one of *Geo. A. Prince & Co.'s* $75 **Melodeons** (5 octaves). These Melodeons are very superior to most Melodeons. We have ourselves used one for three years past, and it has given the highest satisfaction, and is pronounced by all who have heard it, one of the very best. The different priced instruments are of equally good tone—the price varying with the size and style of finish. The size, prices, etc., of these instruments are clearly learned from their Circulars, sent to any one by Geo. A. Prince & Co., Buffalo, N. Y., for an illustrated descriptive catalogue. The instruments given as Premiums, will be sent over directly from the factory at Buffalo, finely boxed, and without expense to the recipient, except for freight. Schools and churches can readily combine their efforts and secure one of these instruments. This has been frequently done. See "N. B," under Premium No. 10.

N. B.—Any higher or lower priced Melodeons will be given for other lists, in the proportion given. See table above.

Premium No. 12—Best Dictionary.

18 Subscribers at $1 each, (or 40 at 80 cts. each,) will entitle the person getting up the club to a copy of the *large Pictorial Unabridged Edition of Worcester's Dictionary,* (Price $7 50.) This now stands confessedly the most valuable Standard Dictionary published. The Dictionary can be called for at any Office, or be sent by Express or otherwise, to any part of the country.

Premiums Nos. 13 to 18—Back Volumes—A First-rate Library.

These premiums (13 to 18,) will enable any one to secure the previous excellent volumes of the *American Agriculturist,* as far back as Volume XVI. These will be sent *postpaid,* in clean, new numbers, each volume by itself, with index. The whole five can be taken together, or one or more copies of any particular volume be selected, as desired. They will be presented as in the table above, viz: For 20 Subscribers at $1 each, (or 37 at 80 cents each,) we will present **six volumes.** For 16 Subscribers at $1 each, (or 30 at 80 cents each,) we will present **five volumes.**—For 13 Subscribers at $1 each, (or 26 at 80 cents each,) **four volumes.**—For 10 Subscribers at $1 each, (or 20 at 80 cents each,) **three volumes.**—For 15 Subscribers at 80 cents each, **two volumes.**—For 10 Subscribers at 80 cents each, **one volume.**—Let every one be careful to name just *which* back volumes are desired.

Premium No. 19—Best File for Agriculturist.

Jacobs' Portfolio File, made just to fit the *Agriculturist*—the name gilded on. This is a leather cover or portfolio, so arranged that successive numbers of the paper can be inserted in a minute, and be properly preserved in book form for reading. When one volume is completed, the sheets can be removed and stitched, and a new volume inserted. A single cover will answer for a dozen successive volumes. It is the most complete file yet made. The price is $1, and the package 20 cents. We will forward it, postpaid, to any one sending *eleven* subscribers, at the lowest club price, (80 cents each.)

Premium No. 20—Paints.

20 Subscribers at 80 cents each, will entitle the person getting up the club to an assortment of *Windsor & Newton's* **Water Color Paints**—consisting of 12 colors, put up in a neat mahogany case, with brushes, etc. These Paints are imported from London, and are by us considered the best in the world. They are adapted to the finest work, or they will make a neat and appropriate present to any of our younger readers. They will be sent post-paid any where in the United States within 3000 miles.

Premium No. 21—Paints.

15 Subscribers at 80 cents each, will entitle the person getting up the club to an Assortment of *Osborne & Hodgkinson's* **Water Color Paints,** consisting of 6 colors, and brushes, put up in a neat case with brushes, cups, etc. These are of American manufacture, and though not so fine as the above, will answer for practice by children or beginners, and for common sketching. Sent same as No. 20.

Premiums Nos. 22 to 26.

We have not space left to describe these particularly, this month. The Cylinder Plow was described in this journal last year. It is remarkably easy draft. Premium The Eagle Plow is well known, and so is the Hay and Straw Cutter, and the Steel-toothed Cultivator, one of the most useful implements in the farm. The Lard and Wire Press is a very convenient household implement, for pressing out lard or tallow, the juice of grapes, currants, berries, &c. For the price, and subscribers required, see the table above.

Advertisements.

Advertisements to be sure of insertion must be received at latest by the 15th of the preceding month.

TERMS—(invariably cash before insertion);

FOR THE ENGLISH EDITION ONLY.

Fifty cents per agate line for each insertion.

☞ Business Notices, *Eighty cents* per line of space.

FOR THE GERMAN EDITION ONLY.

Ten cents per line of *space* for each insertion.
One whole column (175 lines), or more, $40 per column.

☞ Business Notices, *twenty cents* per line of space.

Gardener Wanted.

An unmarried man, competent to raise Summer vegetables for market, and to grow the smaller fruits, will have a good situation in Western Massachusetts, at fair wages. If he can make rustic garden work, he may have employment the year round. Address Dr. WM. H. F., Northampton, Mass.

PEACH TREES.

25,000 one-year old from bud, very thrifty and fine, at $50 per thousand. LENK & CO.,
Humboldt Nurseries, Toledo, Ohio.

SEEDS, PITS, STOCKS, TREES, all of the best quality and low prices. Apple and Pear Seeds, Plum, Peach, and Cherry Pits. Stocks of all kinds, worked or not. Trees, Shrubs and Vines, wholesale and retail. Send for Catalogues. E. C. FROST, Highland Nurseries, (P. O.) N.Y.

DUTCH FLOWERING BULBS.

We offer a large selection of *Hyacinths, Tulips,* and *Crocuses,* etc, etc. A Descriptive Catalogue just published, sent gratis to all applicants. LENK & CO.,
Humboldt Nurseries, Toledo, Ohio.

The Adirondac Grape.

The earliest and best American Grape known, ripening two weeks earlier than any other good grape. Pronounced the most delicious flavor, in fact, equal to the most delicate hot-house grape. Is originated at the base of the Adirondac range of mountains on the shore of Lake Champlain. It is believed it possesses all the properties to establish its character as the EARLIEST AND BEST NATIVE GRAPE.

PRICE. One year old vines $3. A limited number of two year old vines at $5. All cut back to 3 or 4 eyes.

Vines will be carefully packed and forwarded by Express or otherwise. Small packages (less than a pound) can be sent by mail, at 50 cents per ounce, to any part of the United States. Address with remittance

JOHN W. BAILEY, Plattsburgh Nurseries.
Plattsburgh, Clinton Co., N. Y., Oct. 8th, 1862.

GRAPES—GRAPES.

OUR "EXCELSIOR

BURR STONE MILLS,"

AND

ANTI-FRICTION

HORSE POWERS.

Have taken the HIGHEST PREMIUMS WHEREVER EXHIBITED! NINE FIRST PREMIUMS being received from WESTERN STATE FAIRS last year.

THE MILL may be driven by *horse, water, or steam power*, does its work equally as well as the best stone mills in milling establishments, and requires but *one-half the power* to do the same amount of work. They are made in the best manner, and will last *thirty years*, and cost *nothing for repairs*.

THE HORSE-POWER runs upon iron balls, and requires but TWO AND A HALF POUNDS DRAUGHT to keep it in motion. With the same number of horses it will do TWENTY-FIVE PER CENT. MORE WORK than ANY OTHER POWER IN USE.

☞ EVERY MACHINE IS GUARANTEED TO GIVE SATISFACTION, OR THE MONEY WILL BE REFUNDED. ☜

CLARK'S SCHOOL VISITOR,

VOL. VII.

A DAY SCHOOL MONTHLY.

The VISITOR will commence its *seventh volume* with the JANUARY No., 1863. This is the only *Day School Periodical* published at

FIFTY CENTS A YEAR!

Now is the time to form clubs for Winter Schools. Send for a specimen, and see inducement to clubs. Address
DAUGHADAY & HAMMOND, PUBLISHERS,
Philadelphia, Pa.

How to get a Patent.

A 3-cent stamp secures a copy of the "INVENTOR'S GUIDE." Address FOWLER & WELLS, 389 Broadway, New-York.

GODEY'S LADY'S BOOK
For 1863.
GREAT LITERARY AND PICTORIAL YEAR!

The Publisher of Godey's Lady's Book, thankful to that public which has enabled him to publish a magazine for the last *thirty-three* years of a larger circulation than any in America, has made an arrangement with the most popular authoress in this country—

MARION HARLAND

Authoress of "Alone," "Hidden Path," "Moss Side," "Nemesis," and "Miriam,"

who will furnish a story for every number of the Lady's Book for 1863. This alone will place the Lady's Book in a literary point of view far ahead of any other magazine. Marion Harland writes for no other publication. Our other favorite writers will all continue to furnish articles throughout the year.

THE BEST
Lady's Magazine in the World, and the Cheapest.

THE LITERATURE

is of that kind that can be read aloud in the family circle, and the clergy in immense numbers are subscribers for the Book.

THE MUSIC

is all original, and would cost 25 cents (the price of the Book) in the music stores; but most of it is copyrighted, and can not be obtained except in "Godey."

OUR STEEL ENGRAVINGS.

All efforts to rival us in this have ceased, and we now stand alone in this department, giving, as we do, many more and infinitely better engravings than are published in any other work.

GODEY'S

IMMENSE DOUBLE SHEET FASHION-PLATES,

CONTAINING

From five to seven Full length Colored Fashions on each plate. Other fashionplates only have two.

FAR AHEAD OF ANY FASHIONS IN EUROPE OR AMERICA.

DRAWING LESSONS.

No other magazine gives them, and we have given enough to fill several large volumes.

OUR RECEIPTS

are such as can be found nowhere else. Cooking in all its variety—Confectionery—the Nursery—the Toilet—the Laundry—the Kitchen. Receipts upon all subjects are to be found in the pages of the Lady's Book. We originally started this department, and have peculiar facilities for making it most perfect. This department alone is worth the price of the Book.

LADIES' WORK TABLE.

This department comprises engravings and descriptions of every article that a lady wears.

MODEL COTTAGES.

No other magazine has this department.

TERMS, CASH IN ADVANCE.

One copy one year, $3. Two copies one year, $5. Three copies one year, $6. Four copies one year, $7.
Five copies one year, and an extra copy to the person sending the club, $10.
Eight copies one year, and an extra copy to the person sending the club, $15.
Eleven copies one year, and an extra copy to the person sending the club, $20.
And the *only* magazine that can be introduced into the above clubs in place of the Lady's Book is Arthur's Home Magazine.

SPECIAL CLUBBING WITH OTHER MAGAZINES.

Godey's Lady's Book and Arthur's Home Magazine, both one year, for $3 50.
Godey's Lady's Book and Harper's Magazine, both one year, for $4 50.
Godey, Harper, and Arthur will all three be sent one year, on receipt of $6 00.
Treasury Notes and Notes of all solvent banks taken at par. Be careful and pay the postage on your letter.
Address **L. A. Godey,**
323 *Chestnut Street, Philadelphia, Pa.*

Which are the best in use.
The Editors of this Paper, and of nearly all the Weeklies in New-York, buy these articles for home consumption.

MRS. WINSLOW,
AN EXPERIENCED NURSE and Female Physician, presents to the attention of Mothers her
SOOTHING SYRUP
FOR
CHILDREN,
which greatly facilitates the process of Teething, by softening the gums, reducing all inflammation—will allay ALL PAIN and spasmodic action, and is
Sure to Regulate the Bowels.
Depend upon it, mothers, it will give rest to yourselves, and
Relief and Health to your Infants.
It not only relieves the child from pain, but invigorates the stomach and bowels, corrects acidity, and gives tone and energy to the whole system. It will almost instantly relieve
Griping in the Bowels and Wind Colic,
and overcome Convulsions, which, if not speedily remedied, end in death. We believe it the BEST and SUREST REMEDY IN THE WORLD, in all cases of DYSENTERY and DIARRHŒA in children, whether it arises from teething or from any other cause. We would say to every mother who has a child suffering from any of the foregoing complaints—DO NOT LET YOUR PREJUDICE, NOR THE PREJUDICES OF OTHERS, stand between you and your suffering child and the relief that will be SURE—yes, ABSOLUTELY SURE—to follow the use of this medicine, if timely used. Full directions for using will accompany each bottle. None genuine unless the fac-simile of CURTIS & PERKINS, New-York, is on the outside wrapper.
Sold by Druggists throughout the world.
Principal Office, 13 Cedar-Street, New-York.
Price only 25 cents per bottle.

$150. BEST PIANOS. $150.
J. P. HALE & CO. having removed to their new ware rooms
No. 478 BROADWAY,
are now prepared to offer the public a magnificent NEW SCALE, full
7 OCTAVE
ROSEWOOD PIANO,
containing all improvements known in this country or Europe. Over Strung Bass, French Grand Action, Harp pedal, Full Iron Frame.
$150 CASH.
Warranted for Five Years.
Rich moulding cases
$175 TO $200.
All warranted made of the best seasoned material, and to stand better than any sold for $400 or $500, by the old methods of manufacture. We invite the best judges to examine and try these new Instruments, and we stand ready at all times to Test them with any others manufactured in this country. J. P. HALE & CO., 478 Broadway, New-York.

Sectional View.

THE CRAIG MICROSCOPE.
This is the best and cheapest microscope in the world for general use. It has just received the First Premium—Silver Medal—at the Ohio State Agricultural Fair. It requires no focal adjustment, magnifies about 100 diameters, or 10,000 times, and is so simple that a child can use it. It will be sent by mail, postage paid, on the receipt of $2,25, or with six beautiful mounted objects for Three Dollars. Address
HENRY CRAIG,

There are no marked features in the general markets to be noted. The very complete and elaborately prepared tables above, show at a glance the transactions in Breadstuffs as compared with last month, and with last year. Several causes have conspired to depress the prices of wheat and flour. Gold, and consequently foreign exchange, has been lower, giving less margin for profit to shippers, while the demand from Europe has been less active. Weak holders have been scared, and been anxious sellers, which has depressed the market. During several days past, however, there has been a better feeling. and receivers of flour and wheat have held on to their stocks more firmly, while the demand both for shipment abroad and home use has been better. Oats and Barley have advanced materially during the month, as noted in the comparative prices below. They have been scarce, while the home inquiry has been active. Barley, and Barley malt, have reached a price in this market higher than at any previous period within our recollection, and the outlook is fair for a still further advance .... The Cotton market has been quite active, especially within the past two weeks, at decidedly higher rates, leaving the market nearly bare of supplies accessible to purchasers. ....Provisions have been in fair request; but, having been very freely offered, prices of hog products have declined .....Hay and Hops have been in active demand and quoted a shade dearer..... Tobacco has been moderately dealt in at uniform quotations....Wool has been more sought after, and prices have favored sellers ..... Rice has been quiet, in the absence of supplies of desirable lots......The movements in other articles have been of average magnitude .... The changes in the selling rates as compared with last month are indicated below.

CURRENT WHOLESALE PRICES.

	Oct. 18.	Nov. 19.

N. Y. Live Stock Markets.—THE CATTLE MARKETS have been largely supplied during the past month, the average being 5,485 beeves per week. (The weekly average for all of 1861, was 4,265 head.) The supply has exceeded the demand, and prices have fallen off a little ranging at the last general market, Nov. 18th, from 8¾c. to 9c. per lb., estimated dressed weight, for choice fat cattle; 8c.@8½c. for good animals; 6½c.@7½c. for inferior to medium, and 5c.@6c. for poor thin cows and coarse oxen. Average of all kinds 7¼c. Advanced freights, and limited car room on the railroads, with a general thinning out of N. Y. State cattle, indicate a lighter supply and higher prices, within a few weeks.

Veal Calves.—Receipts 776 per week, which is less than would find ready sales at 5½c.@6c. per lb. live weight for fat calves, and 4c.@5c. for coarse to fair veals

Sheep and Lambs.—Lighter receipts, or an average of only 11,853 per week. Trade is lively at higher prices. Pelts are now selling at about $1.75 each, in lots. Prime fat sheep are worth prices equivalent to 5c.@5¼c. per lb., live weight; poor thin sheep sell at 4c.@4½c.; lambs at 4½c.@5½c.; and are scarce. All kinds find ready sales.

Live Hogs.—Have come in at an average rate of **32,050** per week, which is far ahead of the receipts at this season last year. For the week ending Nov. 12th, the arrivals were 40,662! The packing demand was never better, and the facilities for slaughtering, smoking and barreling are so perfect, that even this large number was all used up during the week and prices suffered no decline. Prime, heavy corn-fed hogs are now worth 4⅞c.@5c. per lb. live weight; medium and light, 4¼c.@4½c.; and still-fed, 3½c.@3¾c., an advance of ½c. during the month. Dressed hogs arrive freely.

The Weather has been changeable during the past month, with considerable rain, a respectable snow storm, but no very cold days, 30° being the lowest point reached by the thermometer.——OUR DAILY NOTES, condensed, read: *October* 19, clear and fine, with rain and wind at night—20, 21, cool and clear—22, cloudy with high wind—23, 24, 25, clear, fine—26, light N. E. rain, increasing to heavy storm at night, 27, hard rain, barometer 29° 30′, the lowest point since last March—28 to 31, clear, fine, warm.——*November* 1 to 4, fine and clear—5, cloudy, rain at night—6, light rain A. M., clear, cool P. M.—7, Northeast snow and rain storm, of 8 inches here, of which 4 inches snow left unmelted—8, cloudy and cool, rain at night—9, melting snow storm—10, 11, clear, cool—12, cloudy, rain at night, snow gone—13, 14, clear, warm—15, 16, fine, but cool, barometer 30°70′, the highest for three years—17, light Northeast rain—18, cloudy—19, light rain.

The Rain Fall and melted snow, for month ending Nov. 15th, 6.13 inches, the greatest of which was 3.40 inches on the 26th and 27th of October. The Barometer has ranged from 29.30 to 30.70 inches, an unusual variation of nearly 1⅜ inches.

Thermometer at 6 A. M., New-York.

[Observations carefully made upon a standard Thermometer (Fahrenheit.)—*r* indicates rain—*s*, snow.]

Fruit Growers' Meetings.

These Meetings, held a the Office of the *American Agriculturist*, at 2 o'clock, P. M. on Thursday of each week, continue to increase in interest and value. Recently there has been much discussion on the question: "What 18 or 20 varieties of Pears are best for those who plant for market as well as for home use—the list to include those which will keep up the longest succession of fruit?" There is considerable difference of opinion in regard to a few of the kinds proposed by different leading growers. The question is to be decided by a vote upon each kind, in a general convocation of as many experienced growers as can be got together. The result and other interesting items from the weekly discussions will be published in our next issue.

Business Notices.

☞ *Eighty Cents a Line of space.*

Lands—To All Wanting Farms.

Large and thriving settlement of Vineland, mild climate, 30 miles south of Philadelphia, by railroad; rich soil; fine crops; twenty acre tracts, at from $15 to $20 per acre; payable within four years. Good business openings; good society. Hundreds are settling and making improvements. Apply to CHAS. K. LANDIS, Postmaster, Vineland, Cumberland County, N. J. Letters answered. Papers, containing full information, sent free.

American Agriculturist.

For the Farm, Garden, and Household.

A THOROUGH-GOING, RELIABLE, and PRACTICAL Journal, devoted to the different departments of SOIL CULTURE—such as growing FIELD CROPS; ORCHARD and GARDEN FRUITS; GARDEN VEGETABLES and FLOWERS; TREES, PLANTS, and FLOWERS for the LAWN or YARD; care of DOMESTIC ANIMALS, &c., &c., and to HOUSEHOLD LABORS. It has also an interesting and instructive department for CHILDREN and YOUTH, alone worth the cost of the paper.

A full CALENDAR OF OPERATIONS every month.

THREE to FOUR HUNDRED, or more, illustrative ENGRAVINGS appear in each volume.

Over TWELVE HUNDRED PLAIN, PRACTICAL, instructive articles and useful items, are given every year.

The Editors are all PRACTICAL WORKING MEN.

The teachings of the AGRICULTURIST *are confined to no State or Territory, but are adapted to the wants of all sections of the country—it is, as its name indicates, for the whole* AMERICAN CONTINENT.

TERMS——INVARIABLY IN ADVANCE,
(For either the English or German Edition.)

One copy, one year.............................$1 00
Six copies, one year.............................5 00
Ten or more copies one year.........**80** cents each.

☞ Add to the above rates: Postage to Canada. 6 cents; to England and France, 24 cents; to Germany, 36 cents.

Postage anywhere in the United States and Territories must be paid by the subscriber, and is *only six cents a year*, if paid in advance at the office where received.

All business and other communications should be addressed to the Editor and Proprietor,

ORANGE JUDD, **41** Park-Row, New York City.
